(57) **ABSTRACT**

An elongate body of a medical electrical lead includes at least one conductor formed into a coil that includes a first portion and a second portion, wherein the first portion extends within an outer insulation sheath and the second portion extends outside the outer insulation sheath to be exposed to an environment external to the lead body as an energy dissipating shunt.

**MEDICAL ELECTRICAL LEAD BODY
DESIGNS INCORPORATING ENERGY
DISSIPATING SHUNT**

CROSS REFERENCE TO RELATED
APPLICATION

The present invention is a continuation-in-part of U.S. application Ser. No. 10/909,518, filed Aug. 2, 2004, now U.S. Pat. No. 7,783,365 now published as 20050004643, entitled "Implantable medical device conductor insulation and process for forming," which is a continuation-in-part of U.S. application Ser. No. 10/407,653, filed Apr. 4, 2003, now abandoned now published as 20030216800, entitled "Implantable medical device conductor insulation and process for forming," which is a utility application filed off of U.S. Provisional Application Ser. No. 60/371,995, filed Apr. 11, 2002.

TECHNICAL FIELD

The present invention pertains to medical electrical leads and more particularly to medical electrical leads including energy dissipating shunts.

BACKGROUND

The technology explosion in the medical device industry has resulted in a variety of innovative diagnostic and therapeutic devices and methods. Many implantable medical devices (IMDs), for example, including pacemakers, cardioverter-defibrillators and neural stimulators, are operatively coupled to electrodes, which are joined to elongate lead wires that extend from the devices to a target site either on or within a body of a patient. The electrodes may deliver stimulation therapy and/or sense electrical signals from the patient, for example cardiac depolarization signals, which are used to guide or dictate therapy delivery.

Patients, in which such leads are implanted, may be exposed to a substantial amount of radio frequency (RF) energy, for example, when subject to magnetic resonance imaging (MRI) or radio diathermy processes. An implanted lead wire can act as an antenna during exposure to these RF signals and an appreciable amount of current may thereby be generated in the lead wire, resulting in high current concentration at a surface of a tissue-contacting electrode, for example, implanted to provide pacing stimulation. Much of this current produces heat, due to energy dissipated in a resistance of the electrode-to-tissue interface, which may result in tissue damage in proximity to the electrode. Leads that include an energy dissipating shunt component have been described, for example, in co-pending and commonly-assigned patent application Ser. No. 11/426,207, but there is still a need for novel lead body designs that incorporate more effective energy dissipating shunts.

BRIEF DESCRIPTION OF THE DRAWINGS

The following drawings are illustrative of particular embodiments of the present invention and therefore do not limit the scope of the invention. The drawings are not to scale (unless so stated) and are intended for use in conjunction with the explanations in the following detailed description. Embodiments of the present invention will hereinafter be described in conjunction with the appended drawings, wherein like numerals denote like elements.

2

FIG. 1 is a plan view including a partial section view of a medical electrical lead, according to some embodiments of the present invention.

FIG. 2 is a cross-section view through a conductor of FIG. 1.

FIG. 3 is a plan view including a partial section view of a coaxially constructed medical electrical lead, according to some embodiments of the present invention.

FIG. 4 is a plan view including a partial section view of a multi-conductor medical electrical lead, according to some embodiments of the present invention.

DETAILED DESCRIPTION

The following detailed description is exemplary in nature and is not intended to limit the scope, applicability, or configuration of the invention in any way. Rather, the following description provides practical illustrations for implementing exemplary embodiments of the present invention. Examples of constructions, materials, dimensions, and manufacturing processes are provided for selected elements, and all other elements employ that which is known to those of skill in the field of the invention. Those skilled in the art will recognize that many of the examples provided have suitable alternatives that can be utilized.

FIG. 1 is a plan view including a partial section view of a medical electrical lead 10, according to some embodiments of the present invention. FIG. 1 illustrates lead 10 including an elongate lead body 11 terminated at a proximal end by a connector pin 150 and terminated at a distal end by a stimulation electrode 15. Those skilled in the art will understand that connector pin 150 may be coupled to an implantable pulse generator, for example, a pacemaker device, and that electrode 15 may act as both a sensing and stimulation electrode when coupled to myocardial tissue. According to the illustrated embodiment, electrode 15 is coupled to connector pin 150 by a conductor 104 formed into a coil 114; coil 114 includes a first portion 141, which extends within an outer insulation sheath 112, and a second portion 142, which extends outside sheath 112, to form an energy dissipating shunt when lead 10 picks up radio frequency (RF) energy, for example, during an magnetic resonance imaging (MRI) procedure. According to an alternate embodiment, coil 114 includes more than one conductor 104, being what is known in the art as a multi-filar coil, and the multiple filars or conductors 104 may extend along an entire length of coil 114 between connector pin 150 and electrode 15. FIG. 1 further illustrates another outer insulation sheath 113 extending over coil 114 between second portion, or shunt 142 and electrode 15. Insulation sheaths 112, 113 are formed from insulative material. Exemplary insulative materials include silicone, polyurethane, a combination thereof etc.

FIG. 2 is a cross-section view through conductor 104. FIG. 2 illustrates conductor 104 including a wire 14 having an outer jacket of insulation 24 extending about an entire circumference thereof. Wire 14 may have an outer diameter in a range from about 0.003 inch to about 0.006 inch. Outer jacket of insulation 24 extends at least along a length of conductor 104 that forms second portion or shunt 142. According to embodiments of the present invention, insulation 24 provides a high enough impedance, between wire 14 and an implant environment of lead 10, so that relatively low frequency stimulation pulses may pass through conductor 104 to electrode 15 without current leakage along shunt 142, and provides for a capacitive coupling with the environment external to lead 10 for the current induced by relatively high frequency RF energy, which may be picked up by conductor 104, so that

a high current concentration at the relatively small tissue-contacting surface of electrode **15** is prevented. It should be noted that a length of shunt **142**, and a position of shunt **142**, when lead **10** is implanted, are such that the energy of the relatively high-frequency current will be dissipated over a relatively large surface area, resulting in a reduced local energy density and, thus, a reduced temperature rise, thereby avoiding tissue damage. Insulation **24** may be any dielectric, biostable and biocompatible material, for example an oxide, a polymer, or a ceramic, but is preferably one that can sustain repeated flexing imposed by a cardiac implant environment, either endocardial or epicardial, without sustaining breaches. Insulation jacket **24** may have a thickness in a range from about 0.0001 inch to about 0.001 inch.

According to some embodiments of the present invention, jacket **24** extends along an entire length of conductor **104** to form a primary insulation for sensing and stimulation between connector pin **150** to electrode **15**; according to some alternate embodiments, jacket **24** only extends along a length of conductor **104**, which forms second portion **142** of coil **114**, to act as a primary insulation for only second portion **142**, while outer insulation sheaths **112**, **113** act as a primary insulation for first portion **141** of coil and that portion extending between second portion **142** and electrode **15**, respectively. According to preferred embodiments of the present invention, conductor **104** includes a single conductor wire, for example, wire **14**, which is continuous from a junction with connector pin **150** to a junction with electrode **15**. A length of second portion **142** may be between about 3 centimeters and about 7 centimeters, or even approaching an entire length of lead **10**, for example, between about 30 centimeters and about 110 centimeters; and a length of second insulation sheath **113**, providing a spacing between second portion **142** and electrode **15**, is greater than about 3 millimeters, and, preferably, less than about 6 to 8 centimeters.

FIG. **2** further illustrates wire **14** including an optional 'low-resistance' core **29**, for example, formed from silver, tantalum or gold, to decrease a resistance of wire **14**. Such a decrease may be desirable in order to increase a number of turns of coil **114**, thereby increasing an inductance of conductor **104** without significantly increasing a resistance thereof. Careful selection of increased inductance (e.g. increased number of turns in a coil, etc.) of conductor coil **104** reduces the current induced by the MRI. By increasing the inductive impedance, minimal or no energy is delivered to the tip of the electrode by increasing the high-frequency (i.e. 21 megaHertz (Mhz) to 128 MHz) impedance of conductor **104** to electrode **15**. With reference back to FIG. **1**, according to a preferred embodiment, an outer diameter of coil **114** is increased along second portion **142** in order to be about flush with an outer diameter of adjacent insulation sheaths **112** and **113**. FIG. **1** further illustrates a filler material **124**, for example, formed by silicone rubber, between turns of second portion **142** of coil **114**, which may lend some mechanical stability to portion **142** and may prevent tissue in-growth between the turns. Silicone rubber is commercially available from Silicone Specialties Fabricators located in Elk Rapids, Mich. According to some alternate embodiments, coil **114**, either just along second portion **142**, or along an entire length thereof, may be mounted on a flexible insulative core, which may or may not include a longitudinally extending lumen. Embodiments including such a core may also include filler material **124** along second portion **142**. According to yet further alternate embodiments, first portion **141** of coil **114** may be embedded in sheath **112**.

According to an exemplary embodiment of the present invention, coil **114** of lead **10** is bi-filar, including two of

conductors **104** wound coaxially side-by-side; and key dimensions for lead **10** are as follows: an overall length of lead **10** is about 68 cm; wire **14**, preferably formed from silver-cored MP35N alloy, has a diameter of about 0.003 inch; insulation jacket **24**, preferably formed from one of polytetrafluoroethylene (PTFE), tetrafluoroethylene hexafluoropropylene vinylidene fluoride (THV), a fluorinated terpolymer, ethylene tetrafluoroethylene (ETFE), polyvinylidene fluoride (PVD) THV 400, THV 600, and Si polyimide. Insulation jacket **24** has a thickness of about 0.0005 inch; insulation sheath **112**, preferably formed from polyurethane, has an outer diameter of about 0.055 inch; second portion **142** of coil **114** has an outer diameter of about 0.055 inch and a length of about 6 cm; a pitch of coil **114**, at least along second portion **142** is about 0.012 inch; and insulation sheath **113**, preferably formed from polyurethane, has a length of about 1.5 cm. With respect to the Si polyimide, it is preferable to use hydrolytically stable polyimide. According to this exemplary embodiment, a capacitance of shunt **142** is between about 400 and 500 picoFarads. It should be noted that the Si polyimide insulative jacket may be as thin as about 0.0002 inch to further increase the capacitance. Alternate constructions of leads including shunts that are integral along a length of an electrode conductor thereof, similar in nature to shunt **142**, will be described below.

FIG. **3** is a plan view including a partial section view of a coaxially constructed medical electrical lead **10'**, according to some embodiments of the present invention. FIG. **3** illustrates lead **10'** including conductor coil **114** coupling connector pin **150** to electrode **15**, as previously described for lead **10**, wherein coil **114** includes first portion **141** extending within outer insulation sheath **112** and second portion, or shunt **142** extending outside sheath **112**. According to the illustrated embodiment, a lead body **11'** of lead **10'** further includes another conductor **404** formed into a coil **414** extending about coaxially about coil **114** and isolated therefrom by an inner insulation sheath **412**, for example formed from silicone or polyurethane; conductor **404** couples another electrode **47**, which is disposed proximal to shunt **142**, to a connector ring **470**, which is disposed in proximity to connector pin **150**. Those skilled in the art will appreciate that electrode **47** in conjunction with electrode **15** may form a bipolar pair for sensing and stimulation, however, it should be noted that electrodes **47** and **15** may function independently of one another. According to the illustrated embodiment, inner insulation sheath **412** extends distal of electrode **47** where an outer diameter thereof is increased to be about flush with an outer diameter of electrode **47**; an outer diameter of shunt **142** is preferably about flush with the outer diameter of sheath **412** distal to electrode **47**, which may be about equal to an outer diameter of sheath **112**. Although FIG. **3** illustrates a ring component forming electrode **47**, it should be understood that such a component is not necessary and an exposed portion of coil **414**, distal to sheath **112**, may form electrode **47**.

FIG. **4** is a plan view including a partial section view of a multi-conductor medical electrical lead **30**, according to some embodiments of the present invention. FIG. **4** illustrates lead **30** including an elongate lead body **31** terminated at a proximal end by a connector pin **350** and terminated at a distal end by a first electrode **35**; lead **30** further includes a second electrode **37** disposed proximal to first electrode **35** and a connector ring **370** disposed in proximity to pin **350**. According to the illustrated embodiment, first electrode **35** is coupled to pin **350** by a first conductor **304** formed into a coil **314**, and second electrode **37** is coupled to ring **370** by a second conductor **306** also formed into coil **314**. FIG. **4** further illustrates coil **314** including a first portion **341**, which extends within an

5

outer insulation sheath 312, a second portion 342, which extends outside sheath 312 to form an energy dissipating shunt when lead 30 picks up RF energy, and another outer insulation sheath 313 extending over coil 314 between second portion, or shunt 342 and electrode 35. Second conductor 306 is shown terminated in proximity to a distal end 345 of coil first portion 341 to join with electrode 37, and first conductor 304 is shown extending within a bore of electrode 37, past distal end 345 of first coil portion 341, to second coil portion, or shunt 342. Like shunt 142 (FIG. 1), shunt 342 is shown having an outer diameter about equal to an outer diameter of outer insulation sheath 312.

With reference back to FIG. 2, conductor 304 includes wire 14, which may include the illustrated low-resistance core 29, as previously described, and insulation jacket 24, which extends about an entire circumference thereof to electrically isolate conductor 304 from conductor 306, along first portion 341 of coil 314, and from the environment external to lead 30, along coil second portion, or shunt 342, during transmission of relatively low frequency stimulation pulses from connector pin 350 to electrode 35. According to alternate embodiments, second conductor 306 includes jacket of insulation 24 along first portion 341 of coil 314, and first conductor may only include jacket of insulation 24 along second portion 342 of coil 314. As previously described for conductor 104, insulative jacket 24 around wire 14 of first conductor 304 along shunt 342 provides capacitive coupling for the current induced by relatively high frequency RF energy, thereby preventing a high current density at the relatively small tissue-contacting surface of electrode 35; and a length and disposition of shunt 342 safely dissipates energy of the relatively high frequency current along shunt 342. According to preferred embodiments of the present invention, wire 14 of first conductor 304 is continuous from connector pin 350 to electrode 35.

In the foregoing detailed description, the invention has been described with reference to specific embodiments. However, it may be appreciated that various modifications and changes can be made without departing from the scope of the invention as set forth in the appended claims.

We claim:

1. A medical electrical lead, comprising:
 - a stimulation electrode; and
 - an elongate body including an outer insulation sheath and at least one conductor coupled to the stimulation electrode and formed into a coil;
 - the coil including a first portion, extending within the outer insulation sheath, and a second portion, disposed proximal to the stimulation electrode and extending outside the outer insulation sheath such that the second portion of the coil is exposed to an environment external to the lead body as an energy dissipating shunt; and
 - the at least one conductor including a wire and an insulative jacket extending about an entire circumference of the wire along at least a length of the at least one conductor that forms the second portion of the coil.
2. The lead of claim 1, wherein the insulative jacket serves as both a dielectric component and as a capacitor.
3. The lead of claim 1, wherein the insulative jacket comprises a polymer.
4. The lead of claim 3, wherein the insulative jacket comprises SI polyimide.
5. The lead of claim 4, wherein the insulative jacket comprises hydrolytically stable SI polyimide.
6. The lead of claim 1, wherein an outer diameter of the exposed second portion of the coil is about equal to an outer diameter of the outer insulation sheath.

6

7. The lead of claim 1, wherein a length of the exposed second portion of the coil is between about 3 centimeters and about 7 centimeters.

8. The lead of claim 1, wherein a length of the exposed second portion of the coil is greater than about 6 centimeters.

9. The lead of claim 1, wherein the exposed second portion of the coil is spaced apart from the stimulation electrode by a distance greater than about 3 millimeters.

10. The lead of claim 1, wherein the exposed second portion of the coil is spaced apart from the stimulation electrode by a distance of about 1.5 centimeter.

11. The lead of claim 1, wherein a thickness of the insulative jacket is between about 0.0001 inch and about 0.001 inch.

12. The lead of claim 1, wherein the wire comprises a silver-cored MP35N alloy.

13. The lead of claim 1, further comprising another conductor formed into an outer coil; the outer coil extending about coaxially about the first portion of the coil and within the outer insulation sheath and being terminated proximal to the exposed second portion of the coil.

14. The lead of claim 13, further comprising an electrode coupled to the other conductor and disposed proximal to the exposed second portion of the coil.

15. The lead of claim 13, wherein the outer coil includes a portion extending outside the outer insulation sheath to be exposed to the environment external to the lead body as an electrode.

16. The lead of claim 1, wherein the coil extends within the outer insulation sheath between the second portion of the coil that is exposed to the environment external to the lead body and the stimulation electrode.

17. A medical electrical lead, comprising:

a first electrode and a second electrode disposed proximal to the first electrode; and

an elongate body including an outer insulation sheath and first and second conductors coupled to the first and second electrodes, respectively, and being formed into a coil;

the coil including a first portion, extending within the outer insulation sheath and including a distal end, and a second portion, disposed between the first and second electrodes and extending outside the outer insulation sheath such that the second portion of the coil is exposed to an environment external to the lead body as an energy dissipating shunt;

the second conductor terminated in proximity to the distal end of the first portion of the coil; and

the first conductor including a wire and an insulative jacket extending about an entire circumference of the wire along at least a length of the first conductor that forms the second portion of the coil.

18. The lead of claim 17, wherein an outer diameter of the exposed second portion of the coil is about equal to an outer diameter of the outer insulation sheath.

19. The lead of claim 17, wherein a length of the exposed second portion of the coil is between about 3 centimeters and about 7 centimeters.

20. The lead of claim 17, wherein a length of the exposed second portion of the coil is greater than about 6 centimeters.

21. The lead of claim 17, wherein the exposed second portion of the coil is spaced apart from the first electrode by a distance greater than about 3 millimeters.

22. The lead of claim 17, wherein the exposed second portion of the coil is spaced apart from the first electrode by a distance of about 1.5 centimeter.

23. The lead of claim 17, wherein the insulative jacket comprises a polymer.

7

24. The lead of claim 23, wherein the insulative jacket comprises SI polyimide.

25. The lead of claim 17, wherein a thickness of the insulative jacket is between about 0.0001 inch and about 0.001 inch.

26. The lead of claim 17, wherein the wire comprises a silver-cored MP35N alloy.

27. The lead of claim 17, wherein the second conductor includes a wire and an insulative jacket extending about an entire circumference of the wire and along a majority of a length of the second conductor.

28. A medical electrical lead, comprising:

a stimulation electrode; and

an elongate body including an outer insulation sheath and at least one conductor coupled to the stimulation electrode and formed into a coil;

8

the coil including a first portion, extending within the outer insulation sheath, and a second portion, disposed proximal to the stimulation electrode and extending outside the outer insulation sheath such that the second portion of the coil is exposed to an environment external to the lead body as an energy dissipating shunt;

the at least one conductor including a wire and an insulative jacket extending about an entire circumference of the wire along at least a length of the at least one conductor that forms the second portion of the coil; and

the insulative jacket comprising SI polyimide and having a thickness between about 0.0002 inch and about 0.001 inch.
