(54) Title: ADJUSTABLE IMPLANTABLE GENITOURINARY DEVICE

(57) Abstract

An implantable medical device and method for adjustably restricting a selected body lumen such as a urethra or ureter of a patient to treat urinary incontinence or ureteral reflux. The device includes an adjustable, self-sealing element having a continuous wall, including an inner surface defining a chamber. The adjustable element expands or contracts due to fluid volume introduced in the chamber for restricting a body lumen. After being implanted into a patient, the size of the adjustable element is altered by first locating the adjustable element implanted adjacent the body lumen, and then establishing fluid communication with the adjustable element. The volume of the adjustable element is then adjusted by either introducing or removing volume from the chamber of the adjustable element.

1

ADJUSTABLE IMPLANTABLE GENITOURINARY DEVICE

Field of the Invention

5 The invention relates generally to implantable medical devices and in particular to implantable medical devices for treating urinary incontinence.

Background of the Invention

10 Various implantable devices, such as distensible medical devices, are known in which the distensible medical devices are implanted into the tissue of a human to treat urinary incontinence. These devices have typically relied upon restricting or constricting the urethra of the patient to maintain continence.

15 U.S. Patent 4,773,393 to Haber et al. is an attempt at such a proposed device. U.S. Patent 4,773,393 relates to a hypodermically implantable genitourinary prosthesis which provides an extensible, inflatable tissue expanding membrane to be located in proximal urethral tissue to add bulk to these tissues for overcoming urinary incontinence by localized increase in tissue volume.

20 U.S. Patent 4,802,479 to Haber et al. is an attempt at an instrument for dispensing and delivering material to an inflatable membrane of a genitourinary prosthesis within the tissues of a patient for overcoming urinary incontinence. U.S. Patent 4,832,680 to Haber et al. relates to an apparatus for hypodermically implanting a genitourinary prosthesis comprising an extensible containment membrane for retaining a fluid or particulate matter which is injected from an external source.

25 U.S. Patent 5,304,123 to Atala et al. relates to a detachable membrane catheter incorporated into an endoscopic instrument for implantation into the suburethral region of a patient. Also, U.S. Patent 5,411,475 to Atala et al. discusses a directly visualized method for deploying a detachable membrane at a target site *in vivo*.

30 Once inflated, these devices maintain pressure on the urethra of the patient in an attempt to assist with continence. However, these devices are prone to being under or over inflated at time of implant, leading to undesirable

75712-20

2

postoperative results. For example, if the devices are overinflated it may cause the urethra to be restricted too tightly, and the patient is at risk for retention, a condition where the patient cannot pass urine. Such a condition could lead to kidney damage, necessitating major corrective surgery or at minimum use of self-catheterization to empty the bladder on a regular basis thus increasing the risk of urinary tract infection.

Furthermore, once these devices have been implanted within the patient, the only means of removing them in the event of a postoperative problem or device malfunction is through major surgery. Additionally, once the device has been implanted into the patient there is the possibility of the device migrating back along the pathway created during its insertion, a problem which has been noted with prior art devices. Thus, an important medical need exists for an improved implantable device for treating urinary incontinence.

Summary of the Invention

An implantable device and a method for its use in restricting a body lumen are provided. In one embodiment, the body lumen is a urethra, where the implantable device is used to coapt the urethra to assist the patient in urinary continence. The implantable medical device has the advantage of being adjustable both at the time of implantation and postoperatively. This postoperative adjustability of the implantable medical device allows a physician to regulate the amount of pressure applied to the urethra to ensure continence of the patient and to minimize iatrogenic effects.

In one embodiment of the invention, a patient's incontinence is treated by positioning one or more of the implantable devices adjacent to at least one side of a patient's urethra so as to adjust liquid flow resistance in the urethra. This is accomplished by using the implantable devices to coapt the patient's urethra so as to maintain a transverse cleft or slit structure of the collapsed urethra and thereby provide sufficient flow resistance to ensure continence, while still allowing the patient to consciously discharge urine when necessary.

The device according to one embodiment of the invention is intended to work immediately adjacent to the urethral wall of a patient to create an increase in urethral coaptation and flow resistance. In one embodiment, this

increase in urethral coaptation and flow resistance is due to the displacement of body tissue adjacent to the body lumen. However, in the prior art devices any tissue change which may occur postoperatively such as a reduction in tissue edema associated with the procedure may cause a reduction in clinical effect
5 because of the reduced coaptation and resistance after the swelling has subsided.

In one embodiment, the implantable device for treating urinary incontinence comprises an adjustable element having a continuous wall or membrane, where the wall includes an inner surface defining a chamber. The continuous wall is constructed of at least one material that is substantially self-sealing, and therefore, is able to withstand multiple punctures, for example from
10 non-coring hypodermic needles, during postoperative adjustments of the adjustable element.

In one embodiment, the continuous wall is constructed of a biocompatible resiliently elastomeric polymer or polymer blend of polyurethane, silicone, or the like. In an additional embodiment, the continuous wall of the
15 adjustable element has an outer surface generally defining a sphere. In yet another embodiment, the continuous wall has an outer surface generally defining an elongate body having semi-spherical end portions.

During the postoperative adjustments, the adjustable element is expanded or contracted (*i.e.*, the volume of the adjustable element is increased or
20 decreased) due to fluid volume introduced into the chamber. In one embodiment, fluid volume is introduced into the chamber through a hollow non-coring needle, such as a hypodermic needle, inserted through the wall of the adjustable element. The self-sealing ability of the wall allows for such
25 adjustments by needles during one or more postoperative occasions without compromising the pressure retaining ability of the wall of the adjustable element.

In an additional embodiment, the implantable device includes one or more reinforcing structures positioned between the inner surface and an outer surface of the continuous wall. In one embodiment, woven or layered fibers of
30 polyester, nylon, polypropylene, polytetrafluoroethylene (such as TEFLON) or other polymers having a high durometer measure or high modulus constitute the reinforcing structures. The reinforcing structures help to maintain structural

integrity and the shape of the adjustable element during the initial inflation and any postoperative adjustments made thereafter.

In an additional embodiment, the continuous wall of the adjustable element has a porous polymer structure that allows the movement of water between the outer surface and the inner surface. A hydrophilic polymer is substantially encapsulated in the chamber, where the hydrophilic polymer absorbs water to expand the implantable device. Once implanted within a patient, the volume of the adjustable element is altered (*i.e.*, expanded or contracted) during implantation and/or postoperatively by introducing or removing the hydrophilic polymer from the chamber. In one embodiment, the hydrophilic polymer is hyaluronic acid, polyvinylpyrrolidone, polyethylene glycol, or carboxy methyl cellulose.

In an additional embodiment, the implantable medical device includes a tubular elongate body, such as a conduit, connected to and sealed to the adjustable element. The tubular elongate body includes a first interior passageway extending longitudinally in the tubular elongate body from a first port at the proximal end to a second port in fluid communication with the chamber of the implantable device for adjustably expanding or contracting the adjustable element by applied fluid volume introduced through the first port. Expansion of the adjustable element is accomplished by delivering a fluid material into the first port of the implantable device remote from the adjustable element, but near the patient's skin, thus enabling post-operative adjustment with minimal surgical invasiveness.

The tubular elongate body further includes a second interior passageway extending longitudinally in the tubular elongate body from a proximal opening through the peripheral surface positioned between the proximal and the distal end to a distal opening through the distal end of the tubular elongate body. This second interior passageway is of sufficient diameter to receive an elongate probe member adapted for delivery of the implantable medical device to the desired site in the body tissue of a patient. In one embodiment, the elongate probe member is a solid stylet. In one embodiment, the elongate probe member is an obturator. Alternatively, the elongate probe

75712-20

5

member includes a flexible guidewire which has been initially delivered into the body tissue through a separate hollow stiff probe that has been inserted to the desired location in the body tissue.

5 This embodiment of the implantable device also includes a rear port element coupled to the proximal end of the tubular elongate body. The rear port element including a cavity in fluid communication with the first port of the first interior passageway. An elastic septum is included on the rear port element, and is retained in the rear port element by a clamp ring located around the rear port element.

10 An improvement provided by one embodiment of the present invention resides in the ability to access the implanted rear port element located close to the surface of the patient's skin to adjustably restrict the urethra. This is accomplished by controlling the volume of a fluid, such as a flowable material, in the adjustable element after it has been implanted in the patient. Suitable
15 flowable materials for introduction into the expandable membrane include a saline liquid, a flowable gel, or a slurry of small particles such as silicone in a fluid carrier. Moreover, the flowable material may be made radiopaque to facilitate fluoroscopic visualization for postoperative inspection.

20 The post implantation, or postoperative, urethral restriction is realized by the adjustable element acting on tissue adjacent to the walls of the urethral lumen and forcefully closing the urethral lumen. Voiding of urine from the bladder only occurs when the intravesical pressure overcomes the resistance established by the adjustable element.

25 An important feature of the implantable device of one embodiment of the present invention relates to the adjustable element or membrane which is accessible for subsequent adjustment in volume through the rear port element located under a patient's skin, remotely from the adjustable element. Another important feature of some embodiments of the present invention over the prior art devices is the convenient *in vivo* postoperative adjustability of both pressure and size of the adjustable element.

75712-20

5a

According to another aspect of the invention, there is provided an implantable device for implantation in body tissue, the implantable device comprising: a pressurizable adjustable element which is expandable to enlarged shapes by addition of a flowable material, wherein said adjustable element is adapted for implantation in body tissue adjacent a body lumen and adapted for adjustable coaptation of the body lumen, an elongate conduit element having a distal end and a proximal end, wherein the pressurizable adjustable element is attached to the elongate conduit element near said distal end, wherein said conduit element includes a port portion at said proximal end, and wherein said conduit element has a first passageway connecting said port portion to said adjustable element so that a flowable material provided into said port portion is able to enlarge said adjustable element, wherein said elongate conduit element further comprises a second elongate passageway extending from an opening adjacent the proximal end of the elongate conduit element toward said distal end.

A further aspect of the invention provides an implantable device, comprising: a pressurizable expandable element, attached to an elongate conduit element near its forward end, said conduit element including a rear port portion and having a first passageway connecting said rear port portion to said expandable element, said expandable element expandable to enlarged shapes by addition of a flowable material using an external source provided into said rear port portion, said rear port portion adapted for providing fluid communication between the implantable device and the external source during adjustment and for automatically sealing the flowable material in the implantable device upon removal of the external source, wherein the implantable device is adapted for implantation

75712-20

5b

within body tissue with the expandable element adjacent a body lumen to provide volume to the body tissue for adjustable coaptation of the body lumen.

There is also provided an implantable device assembly, comprising: (a) an elongate guide probe member adapted for being inserted into tissue adjacent a body lumen of a patient; (b) an elongate implantable device adapted for being surgically implanted into the tissue adjacent to the body lumen, said implantable device including a forward expandable element and a rear port portion connected together by flexible conduit, said conduit having a first inner passageway in fluid communication between said expandable element and said rear port portion and having a second passageway adapted for receiving said elongate probe member; and (c) an external source containing a flowable material and adapted for connection to the rear port portion of said implantable device, whereby a flowable material from said external source can be introduced through the rear port portion and through the first passageway of said implantable device so as to expand the forward expandable element adjacent a body lumen to at least partially and adjustably restrict the lumen.

In accordance with a still further aspect of the invention, there is provided an implantable device, comprising: an adjustable element including a continuous wall and an inner surface defining a chamber, wherein the adjustable element is adapted for adjustably expanding or contracting using a fluid introduced into the adjustable element; and a coagulant, wherein the chamber of the adjustable element contains the coagulant which coagulates upon contact with body fluid to assist sealing of an opening in the continuous wall.

75712-20

5c

According to another aspect of the invention, there is provided an implantable device, comprising: an adjustable element including a continuous wall and an inner surface defining a chamber, where at least a portion of the continuous wall of the adjustable element has a porous polymer structure that allows fluid to move between an outer surface and the inner surface of the wall; and a hydrophilic material, wherein the chamber of the adjustable element contains the hydrophilic material which causes the adjustable element to expand or contract due to fluid movement between the outer surface and the inner surface of the wall, and wherein the adjustable element is adapted for placement along side a body lumen to adjust coaptation of the body lumen by expansion and contraction of the adjustable element.

Brief Description of the Drawings

In the drawings, where like numerals describe like components throughout the several views:

7

Detailed Description of the Invention

In the following detailed description, reference is made to the accompanying drawings which form a part hereof and in which is shown by way of illustration specific embodiments in which the invention may be practiced.

5 These embodiments are described in sufficient detail to enable those skilled in the art to practice and use the invention, and it is to be understood that other embodiments may be utilized and that logical, and structural changes may be made without departing from the spirit and scope of the present invention. The following detailed description is, therefore, not to be taken in a limiting sense
10 and the scope of the present invention is defined by the appended claims and their equivalents.

In one embodiment, the present invention provides an adjustable implantable device which restricts urine from involuntarily escaping from the bladder, thus establishing continence for the patient. This adjustable component
15 can be done in a post-operative manner once the patient has resumed daily activity via an evaluation to determine what activities cause bladder stress and observable incontinence.

In Figures 1 (A-D) and 2 of the drawings, there is shown an implantable device 20 for restricting a body lumen. In one embodiment, the
20 implantable device 20 is for treating ureteral reflux of a patient by implanting at least one of the implantable devices adjacent one or both ureteral orifices. In an alternative embodiment, the implantable device 20 is for treating urinary incontinence by implanting at least one of the implantable devices adjacent the urethra.

25 Implantable devices designed for treating urinary incontinence are typically referred to as a genitourinary prosthesis. Many designs for genitourinary prosthesis have been proposed. In one such proposed embodiment, genitourinary prosthesis are comprised of elastomeric, ellipsoidally or spherically-shaped containment membranes which have an interior chamber
30 designed to receive a measured supply of fluid to inflate the prosthesis. One such description of a genitourinary prosthesis is also provided in U.S. Patent Serial No. 6,045,498, entitled "Implantable Device and

75712-20

8

Method for Adjustably Restricting a Body Lumen" issued April 4, 2000, to Burton et al.

5 In one embodiment, the present invention provides an implantable device for adjustably restricting a body lumen, and is suitable for treating both male and female patients suffering from stress incontinence. In treating urinary incontinence, the prosthesis are delivered within the body to a location that is typically within the periurethral tissue and adjacent to the urethra to enable a patient to overcome urinary incontinence by means of increasing both localized tissue volume and passive occlusive pressure upon the urethral mucosa.

10 The prosthesis may be mounted on a hollow non-coring needle, such as a hypodermic needle, which is releasably connected to a fluid source, such as a syringe element. In order to facilitate inserting the prosthesis into position, the prosthesis is housed within a tubular body, such as a trocar tube, where the tubular body is designed to penetrate the tissues of the patient, thus
15 allowing the proper placement of the prosthesis. Alternatively, the prosthesis could be mounted at or on a distal end of a trocar tube to allow for delivery of the prosthesis within the patient.

Once the prosthesis has been positioned within the body, it is inflated by infusing a measured supply of fluid volume, including fluid volume
20 having particulate matter into the interior of the membrane of the prosthesis. Fluids suitable for infusing into the prosthesis include, but are not limited to, sterile saline solutions, polymer gels such as silicone gels or hydrogels of polyvinylpyrrolidone, polyethylene glycol, or carboxy methyl cellulose for example, high viscosity liquids such as hyaluronic acid, dextran, polyacrylic
25 acid, or polyvinyl alcohol for example, or liquids that coagulate on contact with body fluids. The fluids also include fluids having a variety of particulate matter, and include, but are not limited to particles having a spherical shape, an elongate shape, or particles having a cross sectional star shape. Once the prosthesis has been inflated, the needle is withdrawn from the prosthesis and the tubular body is
30 withdrawn from the body, leaving the inflated prosthesis in position.

Figures 1A and 2 shows one embodiment of an implantable device
20 for restricting a body lumen comprising an adjustable, self-sealing element

22, such as an expandable element, having a continuous wall 24. The continuous wall 24 includes an inner surface 26 defining a chamber 28. Furthermore, the continuous wall 24 is constructed of at least one material that is substantially self-sealing to allow for the adjustable element 22 to be expanded or contracted due to fluid volume introduced into the chamber 28. In one embodiment, the continuous wall 24 itself is constructed of a self-sealing material. In an alternative embodiment, the inner surface 26 of the adjustable element 22 has a material that imparts a self-sealing ability to the adjustable element 22 such as crosslinked silicone gel, polyvinylpyrrolidone, or karaya gum for example.

Figures 1B-D show several embodiments of genitourinary prosthesis implanted in a patient. Figure 1B is one embodiment of positioning the adjustable element 22 of the present invention, where one adjustable element 22 is positioned adjacent a urethra 23 of the patient. In an alternative embodiment, Figure 1C shows two of the adjustable element 22 positioned adjacent the urethra 23, where each of the adjustable element 22 are generally disposed on opposite sides of and in a similar plane perpendicular to the urethra 23. In an additional embodiment, Figure 1D shows two of the adjustable elements 22 positioned adjacent the urethra 23, where each of the adjustable elements 22 are generally disposed on opposite sides of the urethra 23, with each of the adjustable elements 22 in generally a different plane perpendicular the urethra 23 to create at least two portions of the urethra having a coapted portion and leading to the urethra 23 having a tortious configuration. In an alternative embodiment, the adjustable element 22 is placed next to a ureteral orifice.

In one embodiment, the continuous wall 24 is intended and designed to be pierced by hollow non-coring needles on one or more occasions for adjusting the volume of the adjustable element during both the implanting of the adjustable element and during subsequent postoperative adjustment of the adjustable element. As such, the continuous wall 24 is constructed of a material that is tear-resistant and biocompatible. In one embodiment, the material is also substantially self-sealing during and after being pierced by a hollow non-coring needle to maintain fluid volume within the chamber 28 of the adjustable element.

In an additional embodiment, the adjustable element 22 has two or

more continuous walls 24, where the continuous walls 24 are arranged concentrically with one of two or more continuous walls 24 being within another continuous wall 24 (not shown). The two or more continuous walls 24 of the present embodiment are separated from each other due to the presence of fluid
5 between the continuous walls 24. In one embodiment, the chambers created by each of the continuous walls 24 are filled with any combination of fluids described within this detailed description.

In one embodiment, the continuous wall is constructed of a biocompatible resiliently elastomeric polymer or polymer blend of polyurethane, silicone, or the like. In this embodiment, the continuous walls 24 stretch as the
10 adjustable element 22 expands or contracts to a desired size. In an alternative embodiment, the continuous wall is constructed of a biocompatible non-resilient polymer or polymer blend of polyethylene, polytetrafluoroethylene, polystyrene, or polyesteretherketone (PEEK). In this embodiment, the continuous wall 24 of
15 the adjustable element 22 expand to a predetermined shape. The adjustable element is formed into a variety of shapes. In one embodiment, the outer surface 32 of the continuous wall 24 generally defines a spherical shape. In an alternative embodiment, the outer surface 32 of the continuous wall 24 generally defines an elongate body having semi-spherical end portions. In one
20 embodiment, a adjustable element 22 being constructed of a biocompatible resiliently elastomeric polymer or polymer blend typically retains the same general cross-sectional shape deflated as when inflated. In an alternative embodiment, when the adjustable element 22 is constructed of a biocompatible non-resilient elastomeric polymer or polymer blend the deflated adjustable
25 element 22 typically has a configuration in which the continuous wall 24 has a folded structure which as the adjustable element 22 is inflated changes to take on a preformed cross-sectional shape and size and/or diameter.

Referring now to Figure 3, there is shown an embodiment of a portion of the continuous wall 24, where the continuous wall 24 further includes
30 one or more reinforcing structures 30 positioned between the inner surface 26 and an outer surface 32 of the continuous wall 24. In one embodiment, the one or more reinforcing structures 30 are designed to support the structural integrity

of the continuous wall 24, helping to provide the substantially self-sealing nature of the adjustable element 22, and to assist in retaining particles within the chamber 28 of the adjustable element 22. In one embodiment, the one or more reinforcing structures 30 are fibers constructed from the group comprising one or more of polyester, nylon, polypropylene, polytetrafluoroethylene (such as
5 TEFLON) or other polymers having a high durometer measure or high modulus constitute the reinforcing structures.

In one embodiment, the fibers of the one or more reinforcing structures 30 form a mesh, such as when woven into a support structure that is
10 positioned between the inner surface 26 and the outer surface 32 of the continuous wall 24. In an additional embodiment, the fibers of the one or more reinforcing structures 30 are less elastic than the continuous wall 24, and the woven support structure has a loose weave configuration to allow for the support structure to expand or contract with the expansion and contraction of the
15 continuous wall 24 of the adjustable element 22.

In an alternative embodiment, the fibers of the one or more reinforcing structures 30 are substantially non-elastic and are arranged in a woven configuration, where the fibers have a kinked structure that allows them to expand or contract with the expansion and contraction of the continuous wall
20 24 of the adjustable element 22.

The one or more reinforcing structures 30 provide the adjustable element 22 with reinforced structural integrity and an increased ability to retain infused particles within the chamber 28 of the adjustable element 22. In one embodiment, the fibers of the one or more reinforcing structures 30 woven into
25 the support structure provide a "rip-stop" function. As an example, the woven support structure allows for rip-stop protection from tears in the continuous wall 24 due to insertion and removal of hollow non-coring needles through the continuous wall 24. In an additional embodiment, the woven support structure prevents the migration of particle from the chamber 28, where the particles are
30 used to inflate the adjustable element 22. In one embodiment, the particles are prevented from migrating out of the chamber 28 due to the tightness of the weave of the support structure.

As previously mentioned, a variety of particulate matter is suitable for infusing into the chamber 28 of the adjustable element 22. The particulate matter is typically suspended in a carrier fluid, or lubricious fluid, however, this is not necessary. Examples of particulate matter shapes include collapsible
5 hollow spheres or those having multiple projecting arms or structures from a central axis. In one embodiment, the structure of the particulate matter has a larger diameter than both the inner diameter of the hollow non-coring needle and the opening in the woven structure of the reinforcing structure 30. To inject the particulate matter into the chamber 28 of the adjustable element 22, the surface
10 of the particulate matter is physically distorted to allow it to pass through the inner diameter of the hollow non-coring needle, such as the hollow spheres collapsing or the projecting arms bending. Once the particulate matter has passed through the hollow non-coring needle, the particulate matter expands back to a size greater than the hole created by the needle, thus making the device
15 self sealing.

In an alternative embodiment, the particulate matter is an elongate body, such as a tubular elongate structure, such that the particulate matter can pass longitudinally through the hollow non-coring needle, but once inside the adjustable element 22 their random orientation would essentially prevent them
20 from passing back through any needle hole created by the hollow non-coring needle.

In an alternative embodiment, the inner diameter of the hollow non-coring needle is sufficient to pass the particulate matter, however the structure of the particulate matter has a larger diameter than the openings in the
25 woven structure of the reinforcing structure 30. In this embodiment, inserting the hollow non-coring needle distorts the mesh of the woven structure of the reinforcing structure 30 to allow the hollow non-coring needle to pass through the continuous wall 24 and into the chamber 28.

Alternatively, the particle is made of a hydrophillic material such as
30 polyvinylpyrrolidone, polyethylene glycol, carboxy methyl cellulose, hyaluronic acid, or the like, which expands once inside the adjustable element 22 due to the absorption of liquid that is either delivered with the particles or passes through at

least a portion of the continuous wall 24 of the adjustable element 22.

In an additional embodiment, a detectable marker 34 is embedded in the continuous wall 24 of the adjustable element 22. The detectable marker 34 allows the adjustable element 22 to be located and its shape to be visualized within the tissues of a patient using any number of visualization techniques which employ electromagnetic energy as a means of locating objects within the body. In one embodiment, the detectable marker is constructed of tantalum and the visualization techniques used to visualize the adjustable element 22 are x-ray or fluoroscopy as are known in the art. In an additional embodiment, the one or more reinforcing structures 30 are labeled with tantalum to allow the adjustable element 22 to be visualized using x-ray, fluoroscopy or other visualization techniques as are known in the art.

Referring now to Figures 4, 5, and 6 there is shown an alternative embodiment of the implantable device 20 further includes a tubular elongate body 36, such as a conduit, where the tubular elongate body 36 has a peripheral surface 38, a proximal end 40 and a distal end 42. The adjustable element 22 has at least one opening through the continuous wall 24 to which the peripheral surface 38 is connected to and sealed to the adjustable element 22. In one embodiment, the adjustable element 22 includes an expandable element. The tubular elongate body 36 is inserted through the first opening 44 and the second opening 46 such that the distal end 42 of the elongate body 36 partially extends beyond the outer surface 32 of the adjustable element 22. The peripheral surface 38 is then sealed to the walls creating the first opening 44 and the second opening 46. In one embodiment, the peripheral surface 38 is sealed to the openings using a chemical or polymer adhesive, such as silicone. In an alternative embodiment, the peripheral surface 38 is sealed to the openings using sonic welding techniques as are known in the art. In one embodiment, the adjustable element is an expandable element.

The tubular elongate body 36 further includes a first interior passageway 48 extending longitudinally in the tubular elongate body 36 from a first port 50 at the proximal end 40 to a second port 52 in fluid communication with the chamber 28 of the implantable device for adjustably expanding or

contracting the adjustable element 22 by applied fluid volume introduced through the first port 50.

In an additional embodiment, the tubular elongate body 36 further includes a second interior passageway 54 extending longitudinally in the tubular elongate body 36 from a proximal opening 56 through the peripheral surface 38 positioned between the proximal end 40 and the distal end 42 to a distal opening 58 through the distal end 42 of the tubular elongate body 36. In one embodiment, the second interior passageway 54 is of sufficient diameter to receive and guide an elongate probe member for the insertion of the implantable device 20 into a human body. In an alternative embodiment, the elongate probe member is removably attached at the distal end 42 and passes outside the adjustable element 22 and along side the elongate body 36 to allow placement of the device without the need for the second interior passageway 54.

The implantable device 20 further includes a rear port element 60 coupled to the proximal end 40 of the tubular elongate body 36. In one embodiment, the rear port element 60 is coupled to the proximal end 40 of the elongate body 36 using chemical adhesives, or alternatively, using sonic welding techniques as are known in the art. In an additional embodiment, the rear port element 60 and proximal end 40 of the elongate body 36 are formed together as one piece in a polymer extrusion process or polymer casting process as are known in the art. In one embodiment, the rear port element 60 and the elongate body 36 are formed of a biocompatible material such as silicone or polyurethane elastomer.

The rear port element 60 includes a cavity 62, where the cavity 62 is in fluid communication with the first port 50 of the elongate body 36. The rear port element 60 also includes an elastic septum 64 through which the cavity 62 is accessed. The elastic septum 64 is retained in the rear port element 60 by a clamp ring 66 located around the rear port element 60. In one embodiment, the clamp ring 66 is made of a biocompatible material, such as, for example, titanium. In one embodiment, the elastic septum 64 is made of a biocompatible material, such as, for example, silicone or polyurethane.

Referring now to Figures 7 and 8, there is shown an alternative

embodiment of the implantable device 20 for treating urinary incontinence or ureteral reflux. The implantable device 20 comprises an adjustable element 100 having a continuous wall 102, including an inner surface 104 and an outer surface 106, where the inner surface 104 defines a chamber 108. The continuous wall 102 also has at least a portion of the continuous wall that is constructed of a porous polymer structure that allows the movement of water between the outer surface 106 and the inner surface 104. A hydrophilic polymer 110 is substantially encapsulated in the chamber 108, where the hydrophilic polymer 110 absorbs water. As the hydrophilic polymer 110 absorbs water, it causes the chamber 108 to expand, thus enlarging the adjustable element 100.

In one embodiment, the continuous wall 102 is intended and designed to be pierced by hollow non-coring needles on one or more occasions for adjusting the volume of the adjustable element during both the implanting of the adjustable element and during subsequent postoperative adjustment of the adjustable element. As such, the continuous wall 102 is constructed of a material that is substantially self-sealing during and after being pierced by a hollow non-coring needle to maintain fluid volume within the chamber 108 of the adjustable element, and the adjustable element expands or contracts by introducing or removing the hydrophilic polymer from the chamber.

Referring now to Figure 8, there is shown an embodiment of a portion of the continuous wall 102, where the continuous wall 102 further includes one or more reinforcing structures 120 positioned between the inner surface 104 and the outer surface 106 of the continuous wall 102. In one embodiment, the one or more reinforcing structures 120 are arranged in a mesh, including fibers in a woven structure. The fibers are constructed from the group comprising one or more of polyester, nylon, polypropylene, polytetrafluoroethylene (such as TEFLON) or other polymers having a high durometer measure or high modulus constitute the reinforcing structures.

In one embodiment, the fibers of the one or more reinforcing structures 120 are woven into a support structure that is positioned between the inner surface 104 and the outer surface 106 of the continuous wall 102. In an additional embodiment, the fibers of the one or more reinforcing structures 120

are less elastic than the continuous wall 102. The woven support structure, in one embodiment, has a loose weave configuration to allow for the support structure to expand or contract with the expansion and contraction of the continuous wall 102 of the adjustable element 100.

5 In an alternative embodiment, the fibers of the one or more reinforcing structures 120 are substantially non-elastic and are arranged in a woven or mesh configuration, where the fibers have a kinked structure that allows them to expand or contract with the expansion and contraction of the continuous wall 102 of the adjustable element 100.

10 The one or more reinforcing structures 120 provide the adjustable element 100 with reinforced structural integrity and an increased ability to retain particles within the chamber 108 of the adjustable element 100. In one embodiment, the fibers of the one or more reinforcing structures 120 woven into the support structure provide a "rip-stop" function. As an example, the woven
15 support structure allows for rip-stop protection from tears in the continuous wall 102 due to insertion and removal of hollow non-coring needles through the continuous wall 102. In an additional embodiment, the support structure prevents the migration of particle from the chamber 108, where the particles are used to inflate the adjustable element 100. In one embodiment, the particles are
20 prevented from migrating out of the chamber 108 due to the size of the mesh of the support structure.

 In an additional embodiment, a detectable marker 122 is embedded in the continuous wall 102 of the adjustable element 100. The detectable marker 122 allows the adjustable element 100 to be located and its shape to be
25 visualized within the tissues of a patient using any number of visualization techniques which employ electromagnetic energy as a means of locating objects within the body. In one embodiment, the detectable marker is constructed of tantalum and the visualization techniques used to visualize the adjustable element 100 are x-ray or fluoroscopy as are known in the art. In an additional
30 embodiment, the one or more reinforcing structures 120 are labeled with tantalum to allow the adjustable element 100 to be visualized using x-ray, fluoroscopy or other visualization techniques as are known in the art.

The hydrophilic material used within the chamber 108 of the adjustable element 100 is selected from a group comprising one or more of polyvinylpyrrolidone, polyethylene glycol, carboxy methyl cellulose, or hyaluronic acid. In one embodiment, the hydrophilic polymer has a particulate structure, where the hydrophilic polymer takes the form of discrete, individual polymeric units. Additionally, the particulate structure of the hydrophilic polymer has an average diameter that is greater than an average diameter of pores of the porous polymer structure. In an additional embodiment, the porous polymer structure of the continuous wall 102 has openings that are less than or equal to 200 micrometers.

In one embodiment, the continuous wall 102 is constructed of a biocompatible resiliently elastomeric polymer or polymer blend of polyurethane, silicone, or the like. In this embodiment, the continuous wall 102 stretches as the adjustable element 100 expands or contracts to a desired size. In an alternative embodiment, the continuous wall 102 is constructed of a biocompatible non-resilient polymer or polymer blend of polyethylene, polyesterterethalate, or high modulus polystyrene, or polyesteretherketone. In this embodiment, the continuous wall 102 of the adjustable element 100 expand to a predetermined shape. The adjustable element 100 is formed into a variety of shapes. In one embodiment, the outer surface 106 of the continuous wall 102 generally defines a spherical shape. In an alternative embodiment, the outer surface 106 of the continuous wall 102 generally defines an elongate body having semi-spherical end portions. In one embodiment, an adjustable element 102 being constructed of a biocompatible resiliently elastomeric polymer or polymer blend typically retains the same general cross-sectional shape deflated as when inflated. In an alternative embodiment, when the adjustable element 102 is constructed of a biocompatible non-resilient elastomeric polymer or polymer blend the deflated adjustable element 102 typically has a configuration in which the continuous wall 102 has a folded structure which as the adjustable element 100 is inflated changes to take on a preformed cross-sectional shape and size and/or diameter.

Referring now to Figures 9 and 10, there is shown an embodiment

of the method of implanting one embodiment of the implantable device assembly 200 of the present invention for restricting a body lumen in a patient. The implantable device assembly 200 is adapted to be surgically implanted into body tissue 202 of a patient adjacent to a body lumen for coapting the body lumen.

5 The implantable device assembly 200 comprises an elongate probe member adapted for being inserted as a guide member into body tissue 202 to locate a portion of the obturator adjacent the body lumen to be restricted. In one embodiment, the elongate probe member is an obturator 206 having a cutting end 208. A physician, after locating the body lumen such as the urethra 23 of a
10 patient, first makes a small incision in skin of the patient 211 and inserts the obturator 206, or elongate probe member, in the body tissue to a desired location adjacent the urethra 23. This procedure is usually carried out under a local anesthetic with visual guidance, for instance by cystoscopy or fluoroscopy by the physician. The obturator 206 is of sufficient strength and rigidity to allow its
15 insertion into the tissue 202 of the patient adjacent and parallel with the urethra 23.

 Referring to Figure 10, an implantable medical device 210, adapted for being surgically implanted into the tissue 202 adjacent to the body lumen, is then positioned onto the obturator 206 and advance into the tissue 202 of the
20 patient. In one embodiment, the obturator 206 is inserted near the meatus urinarius 204 and advance through the periurethral tissue adjacent the urethra 23. In one embodiment, a detent or mark is provided on the obturator 206 which when aligned with a feature on the implantable medical device 210, such as a rear port element 60, ensures that an implantable medical device 210 is
25 appropriately placed at the correct depth in the patient's body tissue. In an additional embodiment, the elongate body 36 of the implantable medical device 210 is available having a variety of lengths to accommodate the patient's anatomic structure so as to facilitate placement of the elastic septum on the rear port element 60 near the patient's skin. Alternatively, the elongate body 36
30 effective length could be made adjustable by it having a helical shape similar to that of a coiled spring.

 While this invention has utility by effecting urethral coaptation for

both male and female patients, the mode of delivery of the device to the site makes it somewhat easier to use for females due to the anatomical differences. In one embodiment, the implantable medical device of the present invention relates to use in female patients. According to its method for use, a physician
5 will initially make a small incision at either side of the meatus, *i.e.* opening of the female urethra. This incision(s) permits an obturator, or a delivery probe member, to be inserted into the body tissue alongside of the urethra so as to define the path of later entry for the implantable device. Next, delivery of the device along the guide probe is made on either one or two opposite sides of the
10 urethra, one placement at a time. The implanted device with the expandable membrane element directed to each location is left in place, with access for adjustment of the membrane size being available through a remote elastic septum in the rear port away from the expandable membrane and located immediately under the skin of the patient.

15 Figure 10 shows one embodiment of the implantable medical device 210, where the implantable medical device 210 includes an adjustable element 22, a tubular elongate body 36, and a rear port element 60. The adjustable element 22 has a continuous wall, including an inner surface defining a chamber. The tubular elongate body 36, has a peripheral surface 38, a
20 proximal end 40 and a distal end 44, where the peripheral surface is connected to and sealed to the adjustable element 22. The tubular elongate body includes a first interior passageway and a second interior passageway, the first interior passageway extending longitudinally in the tubular elongate body from a first port at the proximal end to a second port in fluid communication with the
25 chamber of the implantable device for adjustably expanding or contracting the adjustable element 22 by applied fluid volume introduced through the first port.

The second interior passageway also extends longitudinally in the tubular elongate body 36 from a proximal opening 56 through the peripheral surface 38 positioned between the proximal end 40 and the distal end 44 to a
30 distal opening 58 through the distal end of the tubular elongate body 42. The second interior passageway being of sufficient diameter to receive and guide the obturator 206, or elongate probe member, for the insertion of the implantable

device into the patient's body. The rear port element 60 of the implantable medical device 210 is coupled to the proximal end 40 of the tubular elongate body 36, where the rear port element includes a cavity in fluid communication with the first port of the first interior passageway.

5 In one embodiment, once the obturator 206 has been inserted into the patient's tissue, the portion of the obturator 206 extending from the patient's body is inserted into the distal opening 58 of the second interior passageway. The implantable medical device 210 is then advance or moved along or over the obturator 206 to position the adjustable element 22 adjacent the body lumen to
10 be restricted and to position the rear port element subcutaneously. In one embodiment, the adjustable element 22 is positioned adjacent a urethra. In an additional embodiment, two or more of the implantable medical devices 220 are implanted within the body tissue adjacent a urethra. The obturator 206 is then withdrawn from the tissue of the patient by pulling the obturator 206 through the
15 proximal opening 56 of the second interior passageway, leaving the implantable medical device 210 in position.

Referring now to Figures 11, 12 and 13 there is shown one embodiment of the implantable medical device 210 implanted in the tissue of a patient for restricting a body lumen. In one embodiment, the body lumen is the
20 urethra 23 and the implantable medical device 210 has been implanted in the periurethral tissue of the patient.

After the implantable medical device 210 has been advanced over the obturator 206, or elongate probe member, so that the contracted adjustable element 22 is in the desired position adjacent to the urethra 23, the urethra 23 is
25 restricted to a desired degree by piercing the elastic septum with a needle of a syringe and injecting a flowable material through the first interior passageway into the adjustable element 22. The physician may determine the desired degree of restriction of urethra 23 by means such as infusing fluid through the urethra 23 past the restriction and measuring the back pressure. As illustrated by Figure 11
30 the source of flowable material is usually a syringe 220 with a hollow non-coring needle 222 used to pierce the elastic septum, however alternate fluid containers with means for making a reversible connection to implantable medical device

210 could be used. The flowable material may be, for example, a saline solution, a flowable gel, or a slurry of particles in a liquid carrier. It may be advantageous to make the flowable material radiopaque so that the degree of membrane inflation may be viewed by x-ray.

5 An alternative method of delivery of the implantable medical device 210 could be to first withdraw obturator 206, or elongate probe member, from the body tissue and then inflate adjustable element 22. A further alternative would be to first place the implantable medical device 210 over the obturator 206, or elongate probe member, outside the body and then insert them both into
10 the body tissue as a unit. To facilitate this latter procedure, it may be desirable that there be some friction between the obturator 206, or elongate probe member, and the second interior passageway.

 After the implantable device has been properly positioned with the adjustable element 22 located near the urethra 23 and the elastic septum in rear
15 port element 60 located near the skin, the implantable medical device 210 is injected with a flowable material from the syringe 220. Once filling of the adjustable element 22 is complete, the obturator 206, or elongate probe member, is withdrawn from the implantable medical device 210 leaving the adjustable implantable medical device in the body tissue. Then the skin incision is closed
20 over the rear port element 60 by means such as a suture 230 as shown in Figure 12.

 In an additional embodiment, the presence of the port located near the surface of the patient's skin affords the additional advantage of allowing the device to be easily removed through a small incision in the skin if, for instance, it
25 was to become infected or malfunction, whereas the prior art devices would require major surgery. Furthermore, the presence of the elongate body and the rear port of the implantable device left in the device delivery tract will serve to prevent backward migration of the expandable element along the tract, a problem which has been noted with prior art devices. In an additional embodiment, twists
30 or coils in the implanted device elongate body may permit the body tissue to grow around it and further anchor the implantable device in the patient's body.

 As described, one feature of this invention relates to the

adjustability of the adjustable element 22 postoperatively. This adjustability is effected because the elastic septum is located remote from the adjustable element 22 but near and under the patient's skin. The rear port element 60 and the elastic septum are located by, for instance, manual palpation of the skin region and the
5 needle of the syringe is inserted through the skin and septum so as to add or remove material from the adjustable element 22, thus increasing or decreasing the restriction of the body lumen.

Referring to Figure 13, there is shown one embodiment of the adjustable element 22 implanted adjacent a body lumen. The adjustable element
10 22 is shown in an expanded state, such that it increases both localized tissue volume and passive occlusive pressure upon the body lumen. In one embodiment, the body lumen is the urethra 23 of a patient, and the patient's incontinence is treated by positioning one or more of the adjustable elements 22 of the implantable medical devices 210 adjacent the urethra 23 so as to allow the
15 physician to adjust liquid flow resistance in the urethra 23. This is accomplished by the implantable devices coacting the patient's urethra as previously described so as to maintain a transverse cleft or slit structure of the collapsed urethra and thereby provide sufficient flow resistance, so that enough pressure is provided to maintain continence, but not so much pressure as to prevent the patient from
20 consciously urinating.

In one embodiment, two of the devices are implanted on opposite sides of the urethra so as to effect a balanced urethral coaptation and resistance. If after implantation inflation of the expandable membrane is excessive, thereby creating a disproportionate urethral resistance by obstructing the patient and
25 causing a bladder pressure higher than normal during voiding, damage to the bladder and kidney may ensue. Thus, a post-operative membrane size adjustment is available to reduce the patient's bladder pressure during voiding and maintain intravesical pressure within normal limits. In one embodiment, two individual devices with individual septums are implanted on opposite sides
30 of the urethra. Alternatively, the device may be so configured to have one septum serve both expandable membrane elements. Therefore, the present invention allows a more normal voiding process while maintaining continence in

the patient. This post-operative adjustment feature promotes normal voiding patterns for the patient, and appropriate vesicourethral pressure during voiding. In one embodiment, post-operative adjustment is done in a semi vertical or horizontal position with the bladder full after anesthesia is resolved and edema is minimal.

Referring now to Figures 14 and 15 there is shown embodiments of postoperatively adjusting an implanted adjustable element 22. The adjustable element 22 having been implanted adjacent a body lumen within a patient, is first located within the tissues of the patient. In one embodiment, locating the adjustable element 22 is accomplished using fluoroscopy, x-ray, or ultrasound visualization techniques as are known in the art. Once the adjustable element has been located within the tissue of the patient, the physician then proceeds to establish fluid communication with the adjustable element 22. In Figure 14 one adjustable element 22 having generally a spherical configuration is shown positioned adjacent a body lumen, such as a urethra or a ureteral orifice, of a patient. Alternatively, Figure 15 shows an additional embodiment where two adjustable elements 22 each having a configuration that is generally an elongate body having semi-spherical end portions.

In one embodiment of making an adjustment, fluid communication is established with the adjustable element by first inserting a catheter structure 300 into the urethra of the patient. In one embodiment, the catheter structure 300 has an elongate body 302 proximal end 304 and a distal end 306. The catheter structure 300 includes a fluid passageway extending longitudinally within the catheter structure 300 from an inlet port 308 at the proximal end 304 to a outlet port 310 at the distal end 306. In one embodiment, a hollow non-coring needle 312 is coupled to the outlet port 310. In an additional embodiment, the fluid passageway housed within the elongate body 302 of the catheter structure 300 moves longitudinally within the elongate body 302 to allow the hollow non-coring needle 312 coupled to the outlet port 310 to, in one position, extend beyond the distal end 306 of the elongate body 302, and in another position to be housed completely within the elongate body 302 of the catheter structure 300.

In an additional embodiment, the path of the hollow non-coring needle 312 as it is extended beyond the distal end 306 of the catheter structure 300 deflects away from a plane that is generally parallel with the longitudinal axis of the elongate body 302 of the catheter structure 300. In one embodiment, this allows the hollow non-coring needle 312 to penetrate through the urethral tissue and into the continuous wall of the adjustable element 22. The hollow non-coring needle 312 is then advance into the chamber of the adjustable element 22 at which point the physician adjusts the volume of the adjustable element 22. In one embodiment, the volume of the adjustable element is adjusted by passing fluid and/or particles through the hollow non-coring needle to adjustably contract or expand the adjustable element 22 due to fluid volume introduced into the chamber.

Figure 15 shows an alternative embodiment for adjusting the adjustable element 22, where the catheter structure 300 is first inserted through the tissues of the patient. The distal end of the catheter structure 300 is then aligned with the outside surface of the adjustable element 22 and the hollow non-coring needle 312 is advanced through the continuous wall of the adjustable element and into the chamber to allow the adjustable element to be either expanded or contracted by passing fluid, particles and/or hydrophilic polymer through the hollow non-coring needle 312 as previously described.

In an additional embodiment, the elongate body 302 of the catheter structure 300 acts as a needle stop to limit the depth to which the needle is allow to penetrate the implanted adjustable element 22. In an additional embodiment, the outer surface 32 of the adjustable element is secured to the catheter structure 300 during the insertion of the hollow non-coring needle 312 into the adjustable element 22. In one embodiment, a suction passageway extends longitudinally within the elongate body 302 to allow the distal end 306 of the catheter structure 300 to be secured to the outer surface 32 of the adjustable element 22 by a negative or vacuum pressure applied through the suction passageway. Once the catheter structure 300 is secured to the adjustable element 22, the hollow non-coring needle 312 is extended from the catheter structure 300 to pierce the

WO 98/56311

PCT/US98/12368

25

continuous wall of the adjustable element 22 and allow for its volumetric adjustment.

CLAIMS:

1. An implantable device for implantation in body tissue, the implantable device comprising:

5 a pressurizable adjustable element which is expandable to enlarged shapes by addition of a flowable material, wherein said adjustable element is adapted for implantation in body tissue adjacent a body lumen and adapted for adjustable coaptation of the body lumen,

10 an elongate conduit element having a distal end and a proximal end, wherein the pressurizable adjustable element is attached to the elongate conduit element near said distal end, wherein said conduit element includes a port portion at said proximal end, and wherein said conduit element has a first passageway connecting said port portion
15 to said adjustable element so that a flowable material provided into said port portion is able to enlarge said adjustable element,

wherein said elongate conduit element further comprises a second elongate passageway extending from an
20 opening adjacent the proximal end of the elongate conduit element toward said distal end.

2. A device according to claim 1, wherein said second elongate passageway extends from the opening adjacent the proximal end of the elongate conduit element to said distal
25 end.

3. A device according to claim 2, wherein said second elongate passageway extends from said opening adjacent the proximal end of the elongate conduit element to a second opening at said distal end.

75712-20

27

4. A device according to any one of claims 1 to 3, wherein the adjustable device is implantable in body tissue adjacent a urethra for adjustable coaptation of the urethra.

5. A device according to any one of claims 1 to 4,
5 wherein said port portion is adapted for providing fluid communication between the implantable device and an external source during adjustment and for automatically sealing the flowable material in the implantable device upon removal of the external source.

10 6. A device according to any one of claims 1 to 5, wherein said port portion comprises an elastic septum.

7. A device according to any one of claims 1 to 6, wherein said adjustable element is attached onto said elongate conduit element by a material comprising an
15 adhesive material.

8. A device according to any one of claims 1 to 7, wherein said elongate conduit element permits subcutaneous positioning of the port portion.

9. A device according to any one of claims 1 to 8,
20 wherein the implantable device is constructed using a biocompatible material such as polyurethane or silicone.

10. A device according to any one of claims 1 to 9, wherein the port portion comprises a compression ring for maintaining a seal of the port portion.

25 11. A device according to any one of claims 1 to 10, wherein the adjustable element has a continuous wall including an inner surface defining a chamber,

75712-20

28

wherein the elongate conduit element has a peripheral surface which is connected to and sealed to the adjustable element.

12. A device according to any one of claims 1 to 11,
5 wherein said second passageway is adapted for receiving an elongate probe member.

13. A device assembly comprising:

an implantable device as claimed in claim 11; and

an elongate probe member adapted for being
10 inserted into tissue adjacent a body lumen of a patient.

14. The device assembly according to claim 13, wherein said probe member comprises a stiff elongate rod having a pointed forward end.

15. The device assembly according to claim 12, wherein
15 said probe member comprises a flexible guidewire.

16. A device assembly comprising:

an implantable device as claimed in claim 6; and

a syringe having a forward facing needle whereby
said needle may be sealingly inserted in said septum and a
20 flowable material injected from said syringe through the first passageway to expand the adjustable element.

17. An implantable device, comprising:

a pressurizable expandable element, attached to an elongate conduit element near its forward end, said conduit
25 element including a rear port portion and having a first passageway connecting said rear port portion to said expandable element, said expandable element expandable to

75712-20

29

enlarged shapes by addition of a flowable material using an external source provided into said rear port portion, said rear port portion adapted for providing fluid communication between the implantable device and the external source
5 during adjustment and for automatically sealing the flowable material in the implantable device upon removal of the external source,

wherein the implantable device is adapted for implantation within body tissue with the expandable element
10 adjacent a body lumen to provide volume to the body tissue for adjustable coaptation of the body lumen.

18. The implantable device according to claim 17, wherein said rear port portion comprises an elastic septum.

19. The implantable device according to claim 17,
15 wherein said elongate conduit has a second elongate passageway extending from an opening in the conduit forward tip end to a location rearward from said expandable element.

20. The implantable device according to claim 17, wherein said expandable element is attached onto said
20 elongate conduit element by a material comprising an adhesive material.

21. The implantable device according to claim 17, wherein said elongated conduit element permits subcutaneous positioning of the rear port portion.

25 22. The implantable device according to claim 17, wherein the implantable device is constructed using a biocompatible material such as polyurethane or silicone.

23. The implantable device according to claim 17, wherein the rear port portion comprises a compression ring
30 for maintaining a seal of the rear port portion.

75712-20

30

24. An implantable device assembly, comprising:

(a) an elongate guide probe member adapted for being inserted into tissue adjacent a body lumen of a patient;

5 (b) an elongate implantable device adapted for being surgically implanted into the tissue adjacent to the body lumen, said implantable device including a forward expandable element and a rear port portion connected together by flexible conduit, said conduit having a first
10 inner passageway in fluid communication between said expandable element and said rear port portion and having a second passageway adapted for receiving said elongate probe member; and

(c) an external source containing a flowable
15 material and adapted for connection to the rear port portion of said implantable device, whereby a flowable material from said external source can be introduced through the rear port portion and through the first passageway of said implantable device so as to expand the forward expandable element
20 adjacent a body lumen to at least partially and adjustably restrict the lumen.

25. The implantable device assembly of claim 24, wherein said guide probe member comprises a stiff elongate rod having a pointed forward end.

25 26. The implantable device assembly of claim 24, wherein said guide probe member comprises a flexible guidewire.

27. The implantable device assembly of claim 24, wherein said implantable device rear port portion contains
30 an elastic septum and said source is a syringe having a

75712-20

31

forward facing needle whereby said needle may be sealingly inserted in said septum and a flowable material injected from said syringe through the first passageway to expand the forward expandable element.

5 28. The implantable device assembly of claim 27, wherein said syringe includes an axially movable rear plunger element, whereby the needle is insertable into the elastic septum located in the rear port portion of the implantable device and a flowable material injected by the
10 plunger element through the needle and first passageway to expand the forward expandable element.

29. Use of the implantable device according to any one of claims 1 to 12 and 17 to 23, for variable restriction of a body lumen.

15 30. An implantable device, comprising:

an adjustable element including a continuous wall and an inner surface defining a chamber, wherein the adjustable element is adapted for adjustably expanding or contracting using a fluid introduced into the adjustable
20 element; and

a coagulant, wherein the chamber of the adjustable element contains the coagulant which coagulates upon contact with body fluid to assist sealing of an opening in the continuous wall.

25 31. The implantable device of claim 30, where the fluid is made radiopaque.

32. The implantable device of claim 30, where at least a portion of the continuous wall of the adjustable element has a porous polymer structure that allows body fluid to

75712-20

32

move between an outer surface and the inner surface of the wall.

33. The implantable device of claim 32, where the chamber of the adjustable element contains a hydrophilic material substantially encapsulated in the chamber, where the adjustable element expands as the hydrophilic material absorbs fluid.

34. The implantable device of claim 33, where the adjustable element expands or contracts by introducing or removing the hydrophilic material from the chamber.

35. The implantable device of claim 33, where the hydrophilic material is one or more of hyaluronic acid, polyvinylpyrrolidone, polyethylene glycol, carboxy methyl cellulose, or hyaluronic acid.

36. The implantable device of claim 30, where the coagulant acts as a sealant for punctures to the continuous wall of the adjustable element.

37. The implantable device of claim 30, where the adjustable element has an outer surface generally defining a sphere.

38. The implantable device of claim 30, where the adjustable element has an outer surface generally defining an elongate body having semi-spherical end portions.

39. The implantable device of claim 30, where the fluid includes the coagulant.

40. An implantable device, comprising:

an adjustable element including a continuous wall and an inner surface defining a chamber, where at least a portion of the continuous wall of the adjustable element has

75712-20

33

a porous polymer structure that allows fluid to move between an outer surface and the inner surface of the wall; and

a hydrophilic material,

wherein the chamber of the adjustable element
5 contains the hydrophilic material which causes the adjustable element to expand or contract due to fluid movement between the outer surface and the inner surface of the wall, and

wherein the adjustable element is adapted for
10 placement along side a body lumen to adjust coaptation of the body lumen by expansion and contraction of the adjustable element.

41. The implantable device of claim 40, where the adjustable element expands or contracts by introducing or
15 removing the hydrophilic material from the chamber.

42. The implantable device of claim 40, where the hydrophilic material is one or more of hyaluronic acid, polyvinylpyrrolidone, polyethylene glycol, carboxy methyl cellulose, or hyaluronic acid.

20 43. The implantable device of claim 40, where the hydrophilic material has a particulate structure having an average diameter that is greater than an average diameter of pores of the porous polymer structure.

44. The implantable device of claim 40, where the
25 porous polymer structure has openings that are less than or equal to 200 micrometers.

45. The implantable device of claim 40, where the adjustable element expands to offset a reduction in tissue volume caused by edema.
