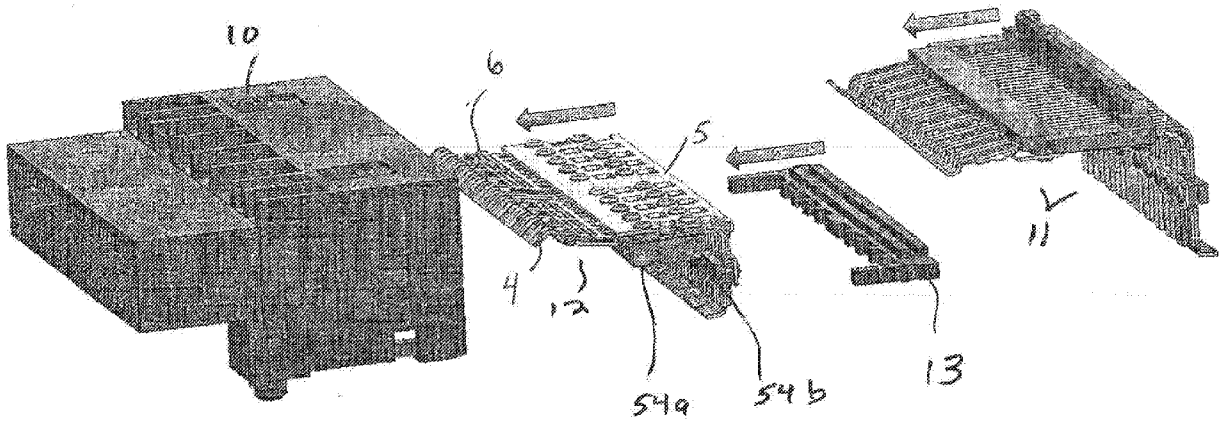
(54) Title: CONNECTOR WITH SHIELDED TERMINALS

Fig. 2



(57) Abstract: Input/output (I/O) connectors (1) for conducting data at high data rates, (e.g. 112 gigabits per second or more) are provided with protective shields (4, 5, 6) to provide increased mechanical strength and signal integrity.

WO 2020/117824 A1

CONNECTOR WITH SHIELDED TERMINALS

RELATED APPLICATION

[0001] This application claims priority to U.S. Provisional Application 62/774,650, filed December 3, 2018, (the "'650 Application") and incorporates by reference herein the entire disclosure of the '650 Application as if it were set forth in full herein.

TECHNICAL FIELD

[0002] This disclosure relates to the field of input/output (I/O) connectors, more specifically to I/O connectors that functions to transmit and receive data at high data rates, (approximately 112 gigabits (Gbits)).

INTRODUCTION

[0003] This section introduces aspects that may be helpful to facilitate a better understanding of the described invention(s). Accordingly, the statements in this section are to be read in this light and are not to be understood as admissions about what is, or what is not, in the prior art.

[0004] Many I/O connectors are configured as a stacked sandwich of wafers and are very sensitive to small dimensional variations. Further, because metal elements in these wafers are oriented at a right angle to a paddle card or module printed circuit board (PCB), electrical contacts connecting a "host" printed circuit board (PCB) to the paddle card or module PCB must often be rotated 90° through what is called a hemi-form. Such a configuration is difficult to construct and assemble. Accordingly, improvements are desirable in the design of such I/O connectors.

SUMMARY

[0005] The inventors describe various exemplary I/O connectors and related methods that allow for high data rate transmissions. The inventive connectors include protective shields to provide increased mechanical strength and signal integrity, among other things.

[0006] One embodiment of an electrical connector may comprise: a housing; and one or more wafers, each wafer comprising at least one flexible and at least one rigid shield, wherein lengthwise portions of each flexible shield are configured at a nominal distance from cantilever beam sections of electrical signal conductors of a corresponding pair of differential signal conductors of a transmission line for affecting an impedance of the transmission line. Such a connector may comprise an octal, small form factor pluggable (OSFP) connector.

[0007] Each transmission line of such a connector may comprise a plurality of electrical terminal end sections of ground and signal conductors, each of the plurality of terminal end sections operable to mechanically and electrically connect the connector to an electronic module (e.g., a PCB).

[0008] In a further embodiment, each flexible shield of a connector may comprise a self-aligning flexible shield configured to cover a first portion of each ground conductor of a transmission line and may be configured to correspondingly flex in substantially the same direction as the respective ground conductors yet maintain a nominal distance from respective signal conductors.

[0009] In embodiments of the invention, each flexible shield may comprise a metal alloy, such as a copper alloy or, alternatively, may comprise a non-metallic material.

[0010] Yet further each flexible shield of an inventive connector may be configured to electrically connect electrical ground sections of a rigid shield to ground conductors of a respective transmission line. Still further, each flexible shield of an inventive connector may comprise secondary end portions (e.g., cantilever springs) configured to mechanically separate lengthwise portions of a flexible shield from cantilever beam sections of a ground conductor.

[0011] In embodiments of the invention the inventive connectors described above and/or elsewhere herein may be configured to operate as an electrical ground and to cover a second portion of each electrical ground conductor of a transmission line.

[0012] Such exemplary rigid shields may be further configured to resist flexing in substantially the same direction as respective electrical ground conductors of a respective wafer.

[0013] Exemplary rigid shields may comprise a metallic material, for example.

[0014] Yet further each rigid shield of an exemplary connector may be connected to respective cantilever beams of ground conductors of a respective wafer to provide mechanical support for the ground conductors.

[0015] Inventive rigid shields that are a part of an inventive connector may comprise a top and rear section, where such sections are configured to align with ground conductors of a respective wafer. A plurality of welds may be used to connect each respective top and rear section to a respective cantilever beam section of a ground conductor of a respective wafer.

[0016] In addition to the connectors described above and herein, the present invention also provides for self-alignable, flexible shields that may be used as part of a high speed connector (e.g., 112 Gbits), where a flexible shield may be configured to correspondingly flex in substantially the same direction as electrical ground conductors of a transmission line of a wafer yet maintain a nominal distance from electrical differential signal conductors of the transmission line.

[0017] The flexible shield may comprise lengthwise portions that are configured to cover a portion of ground conductors of a wafer while maintaining a nominal distance from cantilever beam sections of differential signal conductors of a transmission line to affect an impedance of the transmission line.

[0018] Inventive flexible shields provided by the present invention may comprise octal, small form factor pluggable connectors and may comprise, or be composed of, a metal alloy (e.g. a copper alloy). Alternatively, inventive flexible shields may comprise, or be composed of a non-metallic material.

[0019] Flexible shields provided by the present invention may be configured to electrically connect electrical ground sections of a rigid shield to ground conductors of a transmission line, and may comprise secondary end portions (e.g., cantilever

springs) configured to mechanically separate lengthwise portions of the flexible shield from cantilever beam sections of ground conductors.

[0020] In addition to inventive connectors and flexible shields, the present inventors describe methods, some of which parallel, and involve, the inventive connectors and shields described above and elsewhere herein.

[0021] A further description of these and additional embodiments is provided by way of the figures, notes contained in the figures and in the claim language included below. The claim language included below is incorporated herein by reference in expanded form, that is, hierarchically from broadest to narrowest, with each possible combination indicated by the multiple dependent claim references described as a unique standalone embodiment.

BRIEF DESCRIPTION OF THE DRAWINGS

[0022] The present invention is illustrated by way of example and not limited in the accompanying figures in which like reference numerals indicate similar elements and in which:

[0023] Figures 1 to 3B depict different views of an exemplary I/O connector according to embodiments of the invention.

[0024] Figures 4A and 4B depict perspective views of an exemplary, self-aligning flexible shield according to an embodiment of the invention.

[0025] Figures 5A to 5E illustrate a configuration of an exemplary, self-aligning flexible shield according to embodiments of the invention.

[0026] Figures 6A to 6C depict portions of an exemplary, self-aligning flexible shield configured to function to make electrical and mechanical contact with ground (G) terminal end sections of a wafer according to embodiments of the invention.

[0027] Figure 6D illustrates exemplary dimensions of a self-aligning, flexible shield according to an embodiment of the invention.

[0028] Figures 6E and 6F depict illustrative views of portions of an exemplary self-aligning flexible shield connected to terminal end sections of electrical conductors of an exemplary wafer according to embodiments of the invention.

[0029] Figure 7 depicts a side view of a module PCB mechanically secured, and electrically connected, to terminal end sections of electrical conductors of an exemplary connector according to embodiments of the invention.

[0030] Figures 8A to 8C illustrate an exemplary rigid shield according to embodiments of the invention.

[0031] Figures 9A and 9B illustrate the fastening of an exemplary rigid shield to moldings and a wafer of an exemplary connector according to embodiments of the invention.

[0032] Figure 10A depicts a side view of exemplary connections of an exemplary flexible shield and rigid shield to ground (G) conductors of an exemplary wafer and to one another according to an embodiment of the invention.

[0033] Figure 10B depicts a cross-sectional view of the connections of a portion of a rigid shield to portions of a wafer according to an embodiment of the invention.

[0034] Figure 10C depicts a cross-sectional view of a portion of a rigid shield according to an embodiment of the invention.

[0035] Figure 11 depicts a close-up view of an exemplary weld that may be used to connect a portion of a rigid shield to a ground (G) conductor of an exemplary wafer according to an embodiment of the invention.

[0036] Specific embodiments of the present invention are disclosed below with reference to various figures and sketches. Both the description and the illustrations have been drafted with the intent to enhance understanding. For example, the dimensions of some of the elements in the figures may be exaggerated relative to other elements, and well-known elements that are beneficial or even necessary to a commercially successful implementation may not be depicted so that a less obstructed

and a more clear presentation of embodiments may be achieved. Further, dimensions and other parameters described herein are merely exemplary and non-limiting.

DETAILED DESCRIPTION

[0037] Simplicity and clarity in both illustration and description are sought to effectively enable a person of skill in the art to make, use, and best practice the present invention in view of what is already known in the art. One of skill in the art will appreciate that various modifications and changes may be made to the specific embodiments described herein without departing from the spirit and scope of the present invention. Thus, the specification and drawings are to be regarded as illustrative and exemplary rather than restrictive or all-encompassing, and all such modifications to the specific embodiments described herein are intended to be included within the scope of the present invention. Yet further, it should be understood that the detailed description that follows describes exemplary embodiments and is not intended to be limited to the expressly disclosed combination(s). Therefore, unless otherwise noted, features disclosed herein may be combined together to form additional combinations that were not otherwise described or shown for purposes of brevity.

[0038] As used herein and in the appended claims, the terms "comprises," "comprising," or any other variation thereof is intended to refer to a non-exclusive inclusion, such that a process, method, article of manufacture, or apparatus that comprises a list of elements does not include only those elements in the list, but may include other elements not expressly listed or inherent to such process, method, article of manufacture, or apparatus. The terms “a” or “an”, as used herein, are defined as one or more than one. The term “plurality”, as used herein, is defined as two or more than two. The term “another”, as used herein, is defined as at least a second or more. Unless otherwise indicated herein, the use of relational terms, if any, such as “first” and “second”, “top”, “bottom”, “rear” and the like are used solely to distinguish one entity or action from another entity or action without necessarily requiring or implying any actual such relationship, priority, importance or order between such entities or actions.

[0039] The term “coupled”, as used herein, means at least the energy of an electric field associated with an electrical current in one conductor is impressed upon another conductor that is not connected galvanically. Said another way, the word “coupling” is not limited to either a mechanical connection, a galvanic electrical connection, or a field-mediated electromagnetic interaction though it may include one or more such connections, unless its meaning is limited by the context of a particular description herein.

[0040] The use of “or” or “and/or” herein is defined to be inclusive (A, B or C means any one or any two or all three letters) and not exclusive (unless explicitly indicated to be exclusive); thus, the use of “and/or” in some instances is not to be interpreted to imply that the use of “or” somewhere else means that use of “or” is exclusive.

[0041] Terminology derived from the word "indicating" (e.g., "indicates" and "indication") is intended to encompass all the various techniques available for communicating or referencing the object/information being indicated. Some, but not all, examples of techniques available for communicating or referencing the object/information being indicated include the conveyance of the object/information being indicated, the conveyance of an identifier of the object/information being indicated, the conveyance of information used to generate the object/information being indicated, the conveyance of some part or portion of the object/information being indicated, the conveyance of some derivation of the object/information being indicated, and the conveyance of some symbol representing the object/information being indicated.

[0042] The terms “including” and/or “having”, as used herein, are defined as comprising (i.e., open language).

[0043] It should also be noted that one or more exemplary embodiments may be described as a method. Although a method may be described in an exemplary sequence (i.e., sequential), it should be understood that such a method may also be performed in parallel, concurrently or simultaneously. In addition, the order of each formative step within a method may be re-arranged. A described method may be

terminated when completed, and may also include additional steps that are not described herein if, for example, such steps are known by those skilled in the art.

[0044] As used herein, the term "embodiment" or “exemplary” mean an example that falls within the scope of the invention(s).

[0045] Referring now to Figure 1 there is depicted an exemplary I/O connector 1 according to an embodiment of the invention. As depicted, the connector 1 may be an octal, small form factor pluggable (OFSP) connector that functions to mechanically and electrically connect a host printed circuit board (PCB) 2 to a module PCB 3. In embodiments, the data rate of transmissions conducted by electrical elements of the connector 1 and PCBs 2,3 may be 112 Gbits per second (Gbps), for example.

[0046] Figure 2 depicts an exploded view of an exemplary I/O connector 1 comprising a housing 10, a wafer 12 with both flexible shields 4, 6 and rigid shield 5 attached, another wafer 11 with both flexible shields and a rigid shield attached and a bumper 13. For purposes of explanation only, wafer 11 may be referred to as a “first” or “top” wafer while wafer 12 may be referred to as a “second” or “bottom” wafer. Further, it should be understood that an inventive connector may comprise more than two wafers, more than one of each type of wafer and each wafer may be connected to one or more flexible and/or rigid shields.

[0047] In an embodiment the bumper 13 may function to limit the movement of wafer 11. For example, the bumper 13 may exert a force on a base of the rigid shield attached to wafer 11. In an embodiment the bumper is composed of a plastic, for example.

[0048] With reference now to Figure 3A, there is depicted the I/O connector 1 in Figure 1 with its housing 10 removed to enable the reader to view elements of the connector 1. As depicted a plurality of electrical, terminal end sections 11a to n (where “n” indicates the last section) of ground (G) and signal (S) conductors of top wafer 11 and electrical, terminal end sections 12 a-n of ground (G) and signal (S) conductors of bottom wafer 12 (though the latter is only partially shown) are depicted, respectively. The module PCB 3 may be mechanically and electrically secured and connected, to the connector 1 by press fitting or otherwise inserting the module PCB 3 in between

the plurality of terminal end sections 11a-n of ground (G) and signal (S) conductors on a top surface of the PCB 3 and the plurality of terminal end sections 12 a-n of ground (G) and signal (S) conductors on a bottom surface of the PCB 3 (see also Figure 7). In an embodiment, each terminal end section 11a-n, 12a-n may comprise a terminal end of an electrical conductor where a set of four conductors may be referred to as a transmission line. In an embodiment, each one of the four conductors making up a transmission line may be operable to function either as a ground (G) or signal (S) conductor. In an embodiment wafer 11 and wafer 12 may comprise a plurality of parallel positioned transmission lines, where each transmission line comprises two parallel signal conductors and two parallel ground conductors and their respective electrical, terminal end sections configured in a G-S-S-G arrangement to make mechanical and electrical connection with module PCB 3.

[0049] In some embodiments, a transmission line may be made of an insert molding. Further, it should be understood that the number of transmission lines and type of transmission lines in a wafer depicted in the figures is merely exemplary. Accordingly, a wafer may contain as many double-ended or single-ended transmission lines or other lines as desired. The structure of an exemplary wafer may be stiff in order to provide support for solderable elements. Accordingly, plastic supports that might otherwise be used for this purpose are not needed. Further, such a stiff wafer structure provides support when the terminal end sections 12 a-n are contacted to a paddle card or PCB. In more detail, as terminal end sections 12 a-n (i.e., terminal ends) make contact with a paddle card or PCB, a certain minimum force may be applied by the stiffness of the wafer at the interface between the terminal end sections 12 a-n and the paddle card or PCB to ensure good electrical connection.

[0050] Figure 3B depicts a rear view of the exemplary I/O connector 1. As shown wafer 11 may comprise a plurality of tail sections 110a to n of which may be soldered to points on the host PCB 2. Though not shown, tail sections of wafer 12 may similarly be soldered to points on the host PCB 2**.** In an embodiment, an exemplary width of a tail section may be 250 microns and a spacing between each section may be 0.6mm (i.e., a 0.6 mm pitch).

[0051] Referring now to Figures 4A and 4B there is depicted perspective views of an exemplary, self-alignable flexible shield 4 according to an embodiment of the

invention. As shown the exemplar shield 4 may comprise a plurality of terminal end portions 42a to n, where "n" represents the last end portion (only portions 42a to 42e are shown) and a plurality of secondary end portions 44a-n connected by a shield body 45. Also shown in Figure 4A are two indicators p_{1a} and p_{1b} for flexible, longitudinal and transverse portions, respectively, of shield 4 that, collectively, make up an area that substantially corresponds to the body 45 of shield 4. Said another way, a plurality of flexible, longitudinal and transverse portions p_{1a} and p_{1b} make up an area of the body 45 of shield 4. In more detail one longitudinal portion p_{1a} may extend from the longitudinal end of portion 42a to the longitudinal end of portion 44a and may have a width substantially equal to width of portion 42a (e.g., end of a terminal), while a transverse portion p_{1b} may extend from the lower transverse end of portion 42a to the upper transverse end of portion. Figure 6D provides some exemplary dimensions of an inventive shield 4. A more detailed discussion of these portions is set forth elsewhere herein.

[0052] Referring now to Figures 5A to 5E there is illustrated a configuration of exemplary, self-aligning flexible shields 4, 6, where each shield 4, 6 may be configured to cover a first portion of ground conductors within conductors of bottom wafer 12. The conductors and their integral terminal end sections 12a-n making up a transmission line may be configured as an exemplary, cantilever-beam constructed conductor, for example.

[0053] As will be explained in more detail herein, a flexible shield provided by the present invention, such as shield 4 for example, may be relatively thin (see exemplary dimensions in Figure 6D) and may be configured to correspondingly bend, deflect of flex (collectively "flex") in substantially the same direction and at substantially the same time as the ground (G) terminal end sections of ground conductors of a wafer flex yet maintain a nominal distance from respective signal (S) terminal end sections of signal conductors. For example, shield 4 may be connected to a plurality of terminal end sections 12a-n and may flex when one or more of the ground (G) terminal end sections 12a-n flexes without applying a force on the remaining contact end sections 12a-n.

[0054] In embodiments of the invention inventive flexible shields may be composed of a metal alloy, such as a copper alloy (e.g., C70250 or C70252).

[0055] In embodiments, flexible shields provided by the present invention may function to mechanically and electrically connect terminal end sections of ground (G) conductors to one another (see Fig. 6A where shield 4 connects sections 12a,d) as well as electrically connect ground (G) sections of a rigid shield 5 to the ground conductors (see Fig. 7, where ground sections 51a,52a of rigid shields are electrically connected to cantilever beams sections 120a, 130a of ground (G) conductors by secondary end sections 43a, 44a (e.g., spring-like, deformable end sections) of wafers 11,12.

[0056] In addition, further functions of an inventive flexible shield are to shield conductors of a transmission line of a respective wafer that the shield covers from electromagnetic interference (EMI)(e.g., cross-talk) from transmission lines of adjacent wafers and to adjust or otherwise contribute to the overall impedance of the electrical ground (G) of a given wafer.

[0057] In an alternative embodiment, rather than be composed of a metal alloy inventive flexible shields may be composed of a non-metallic material for electrical conduction. In such an embodiment it is expected that the shield could still function to connect ground conductors of a transmission line to one another, however, the ability to shield the conductors of transmission lines from EMI is expected to be reduced.

[0058] Figure 5D illustrates an enlarged version of Figure 5B that depicts a terminal end portion 42a of the shield 4 in aligned, electrical and mechanical contact with a ground (G), terminal end section 12a of wafer 12. As shown the portion 42a is shaped as an open-ended rectangle. However, the shape of the portion 42a need not be an open-ended rectangle. Rather, portion 42a may be formed to make mechanical and electrical contact with the shape of a particular ground (G), terminal end section of a particular wafer. Figures 5B and 5D depict the portion 42a aligned, yet unsecured to ground (G), terminal end section 12a while Figures 5C and 5E depict the portion 42a aligned and secured to ground (G), terminal end section 12a.

[0059] In more detail, in an embodiment, after the shield 4 is aligned over wafer 12 (described further herein) each of the aligned portions 42a-n may be crimped to (i) prevent the shield 4 from moving once it is aligned over wafer 12, (ii) to assist in maintaining a desired spacing between terminal end sections 12a-n as well as (iii) to

make a secure, mechanical and electrical connection with a respective ground (G), terminal end sections 12a-n of wafer 12 though it should be understood that crimping is just one means or method of preventing the shield 4 from moving and for mechanically and electrically securing portions of a flexible shield to ground (G), terminal end sections of a wafer.

[0060] It should be understood that an exemplary flexible shield may be similarly configured over top wafer 11, though the ground (G), terminal end sections 11a-n of wafer 11 are bent up instead of down as in sections 12a-n and crimped.

[0061] In embodiments of the invention, portions of an inventive flexible shield are configured to function to make electrical and mechanical contact with ground (G) elements of a wafer and do not so function to make contact with signal (S) elements of the wafer. For example, referring now to Figures 6A to 6C there is depicted portions 42a,b,c of the shield 4 configured to function to make electrical and mechanical contact with ground (G), terminal end sections 12a,d,g of wafer 12 and do not so contact signal (S), terminal end sections 12b,c,e,f of wafer 12.

[0062] Figure 6A depicts a close-up view of an exemplary flexible shield 4. As illustrated, portions 42a,b of one end of the shield 4 are configured to function to make electrical and mechanical contact with ground (G), terminal end sections 12a,d of wafer 12 and do not so contact signal (S), terminal end sections 12b,c of wafer 12. The opposite end of the shield 4 comprises secondary end portions 44a-n configured to function to make electrical and mechanical contact with electrical ground (G) sections of a rigid shield (not shown in Figure 6A).

[0063] Figures 6B and 6C depict a view of portions 42 b, c of one end of the shield 4 configured to function to make electrical and mechanical contact with ground (G), terminal end sections 12d,g of wafer 12 via crimping without contacting signal (S), terminal end sections 12e,f of wafer 12.

[0064] Figure 6D illustrates exemplary dimensions of a flexible shield 4 according to an embodiment of the invention, it being understood that each of the dimensions shown in Fig. 6D may be modified to correspond to the configuration of ground conductors of transmission lines a shield is connected to.

[0065] Referring now to Figures 6E and 6F there is illustrated top and bottom views, respectively, depicting the ground (G), terminal end sections 12a, d formed such that each includes an indentation 420a,d for receiving a portion 42a,b of the shield 4. The indentations further function to help prevent the corresponding portions 42a, b of the shield 4 (and the shield 4 itself) from moving.

[0066] With reference now to Figure 7, there is depicted a side view of module PCB 3 mechanically secured, and electrically connected, to terminal end section 11a on a top surface of the PCB 3 and terminal end section 12a on a bottom surface of the PCB 3 by press fitting or otherwise inserting the module PCB 3 in between sections 11a,12a. While only one of each terminal end section 11a-n, 12a-n is shown it should be understood that each terminal end section11a-n and 12a-n may make similar mechanical and electrical connection to the module PCB 3.

[0067] Figure 7 also depicts portion 41a of one end of shield 6 configured to function to make electrical and mechanical contact with ground (G), terminal end section 11a of top wafer 11 and portion 42a of one end of shield 4 configured to function to make electrical and mechanical contact with ground (G), terminal end section 12a of bottom wafer 12. Further, as shown the opposite ends of shields 4,6 comprise secondary end portions 44a,43a, respectively, each configured to function to make electrical connection to, and mechanical contact with, ends 51a, 52a of ground sections of rigid shields and with cantilever beam sections 120a,130a, respectively of ground conductors (not shown in Figure 7).

[0068] Though Figure 7 depicts the connection of the flexible shields 4,6 to ground conductors we shall utilize Figure 7 to explain additional functions and features of inventive flexible shields provided by the present invention. In accordance with embodiments of the invention, the shields 4, 6 cover respective portions (i.e., first portions) of ground (G) conductors 12a-n of transmission lines of wafer 12. To provide a desirable impedance and resulting return loss for a transmission line that includes differential signal (S) conductors (again, not shown in Figure 7, but see for example, sections 12b,c in Figure 6B) a lengthwise, longitudinal portion p_{1A} of each shield 4,6 may be configured at a nominal distance d_1 (e.g., 0.15 millimeters, nominal) from a cantilever beam section of electrical signal (S) conductors of a corresponding pair of

differential signal (S) conductors of a transmission line to, for example, affect an impedance of the transmission line.

[0069] In an embodiment, the secondary end portions 43a, 44a (e.g., opposing cantilever springs) of flexible shields 4, 6 may function to assist in the mechanical separation of each lengthwise portion p_{1A} of a respective shield 4, 6 from cantilever beam sections of each (S) signal conductor of a corresponding pair of differential signal (S) conductors in order to provide a desirable return loss for a transmission line. Accordingly, shields 4, 6 may function as a desired common mode reference.

[0070] More generally, in embodiments of the invention, each lengthwise, longitudinal portion p_{1A} of a particular flexible shield may be configured at a nominal distance d_1 from a corresponding cantilever beam section of a (S) signal conductor of a corresponding pair of differential signal (S) conductors to provide a desirable impedance and resulting return loss for a transmission line. Said another way, based on a desirable impedance or its associated return loss for a given transmission line of a connector, a shield may be configured a specified distance d_1 away from a corresponding cantilever beam section of each (S) signal conductor of a corresponding pair of differential signal (S) conductors, where the distance d_1 achieves such an impedance/return loss.

[0071] Though shown as a circular or oval shape in Figure 7 it should be understood that the secondary end portions 43a,44a (e.g., opposing cantilever springs) may be configured and formed in alternative shapes provided such an alternative shape functions to mechanically separate a lengthwise, longitudinal portion p_{1A} of a respective shield from a cantilever beam section of a (S) signal conductor of a corresponding pair of differential signal (S) conductors in order to provide a desirable impedance/return loss for a transmission line.

[0072] It should be noted that Figure 7 depicts a side view. Accordingly, lengthwise portion p_{1A} in actuality represents one flexible, longitudinal portion of an area of flexible shield 4. As noted previously in our discussion of Figure 4A, p_{1a} is one of many flexible, longitudinal portions that make up an area that substantially corresponds to a flexible body 45 of flexible shield 4.

[0073] In addition to impedance affects, the inventive flexible shields are believed to affect the resonant frequencies and cross-talk performance of connectors provided by the present invention.

[0074] In more detail, the flexible, longitudinal portions p_{1A} may be said to create a responsive, electromagnetic cavity in the longitudinal direction of the path of a signal being conducted through a conductor of a wafer. In particular, in embodiments of the invention as the length of longitudinal portions p_{1A} of shield 4 are progressively shortened the resonant frequency modes that can be generated by the corresponding, resulting cavity are believed to progressively increase in frequency.

[0075] As described in more detail below, the increased proximity of mechanical welds (see welds 600a to 600d in Figure 10A) is also believed to result in a shifting of the resonant frequencies to higher frequencies within such a cavity.

[0076] Further, the inventors have discovered that the flexible shields 4, 6 as shown in the figures and as described herein improve cross-talk between signal (S) conductors of wafers 11, 12, for example. In more detail, the transverse, flexible portions p_{1b} create a proximate Faraday cage with a near field boundary to differential signal (S) conductors covered by the shield 4.

[0077] As mentioned previously, the inventive flexible shields and corresponding transverse, flexible portions p_{1b} flex as the corresponding ground (G) conductors of a transmission line they are attached to flexes. Accordingly, this ability to flex allows a respective flexible shield to create and maintain an electromagnetic boundary that reduces the energy of an electric field generated by the signal (S) conductors of the transmission line thereby limiting the adverse coupling of components of such an electric field to differential signal conductors of transmission lines within an adjacent wafer.

[0078] Referring now to Figures 8A to 8C there is depicted a second shield 5 comprising top and rear sections 53a, 53b, respectively. In an embodiment, the entire shield 5 may be considered an electrical ground (G).

[0079] According to an embodiment of the invention, shield 5 may comprise a rigid shield. In comparison with the inventive flexible shields, inventive rigid shields

provided by the present invention, such as shield 5 for example, may be configured to be dimensionally thicker than flexible shields and resist flexing in substantially the same direction and at substantially the same time as the ground (G) conductors (i.e., cantilever beam sections 120a, 130a) of wafers they are connected to. In embodiments of the invention rigid shields may be composed of a metallic material such as a copper alloy (e.g., C70250 or C70252). Alternatively, rigid shields may be composed of a plastic. When rigid shields are composed of a metal alloy they may be made using a metal stamping process.

[0080] In each embodiment, an inventive rigid shield may be configured to cover a second portion of each of the electrical ground conductors (i.e., the flexible shield covers a first portion) and may be connected to the cantilever beams of a ground (G) conductor of a wafer thereby functioning to provide mechanical support for the ground conductors and to provide a combined structure that withstands warping and other external forces.

[0081] As shown, the top section 53a may comprise a plurality of openings 56a-n, where each of the openings 56a-n functions to alignably receive a fastening structure 55a-n of a first molding 54a, such as a deformable peg or post composed of a plastic (e.g., a high temperature thermoplastic such as a liquid crystal polymer or "LCP"), for example. The combination of the structures 55a-n and openings 56a-n may function to align the top section 53a of the shield 50 with a top of the first molding 54a thereby aligning the top section 53a with ground conductors of the wafer 12 as described in more detail below. In an embodiment, the structures 55a-n may be a part of the first molding 54a.

[0082] With continued reference to Figures 8A and 8B, in an embodiment the rear section 53b of the shield 5 may be a movable section that is configured at an initial counter-clockwise obtuse angle of ***x*** degrees with respect to the top section 53a (e.g., 115 degrees, or 25 degrees counter-clockwise from a geometric plane that is at a right angle to the top section 53a) to permit the top section 53a of the shield 5 to be aligned with the first molding 54a and ground conductors of wafer 12 before the rear section 53b is moved to be aligned with ground conductors of the wafer 12, thus eliminating the need to simultaneously align both the top and rear sections 53a,53b of the shield 5 at the same time. In an embodiment, one the rear section 53b is moved

into an aligned position with ground conductors of the wafer 12 it will remain there until it is connected as described below.

[0083] Upon aligning the top section 53a, the rear section 53b may then be aligned. Referring to Figure 8C, in an embodiment, the rear section 53b may comprise a plurality of openings 58a-n (openings 58a-n are shown under the structures 57a-n), where each of the openings 58a-n functions to receive a second fastening structure 57a-n of a second molding 54b, such as a deformable peg or post composed of a plastic (e.g., a high temperature thermoplastic such as a liquid crystal polymer or "LCP"), for example, for example. The combination of the structures 57a-n and openings 58a-n may function to help align the rear section 53b of the shield 5 with the second molding 54b, thereby aligning the rear section 53b with ground conductors of the wafer 12 as described in more detail below. In an embodiment, the structures 57a-n may be a part of the second molding 54b.

[0084] It should be understood that while the discussion above focuses on aligning the top section 53a of the shield 5 for fastening prior to aligning the rear section 53b, this is merely exemplary. Alternatively, the rear section 53b may be aligned for fastening prior to top section 53a. In either case, the combination of the deformable structures and openings functions to self-align both the top and rear sections 53a,b of shields 4,5 over the moldings 54a,b thereby aligning the top and rear sections with ground conductors of the wafer 12. Thus, it may be said that the shields 4,5 are "self-alignable" or "self-aligning".

[0085] Continuing, after a section 53a,53b of shield 5 is aligned and positioned as described above it may be fastened to a respective molding 54a,b. Referring now to Figures 9A and 9B there is illustrated the fastening of the top and rear sections 53a,b of shield 5 to moldings 54a,b connected to wafer 12.

[0086] In Figure 9A, each of the deformable fastening structures 55a-n of the first molding 54a that has been received by an opening 56a-n of the shield 5, for example, may be deformed (i.e., flattened or "mushroomed") by a heat staking process, for example, after passing through a respective opening 56a-n in order to increase a diameter of an end of such a structure 55a-n to a value that is greater than the value of a diameter of a respective opening 56a-n (i.e., the deformed end is wider

than the opening) to securely fasten the top section 53a of the shield 5 to the first molding 54a which is also connected to ground conductors of the wafer 12 as described in more detail below. In an embodiment, molding 54a may be configured as a box with structure around a periphery and an opening in the middle to allow for welding, for example (see Figure 10A).

[0087] One exemplary heat staking process may utilize a pulsed laser that heats each end of structures 55a-n to deform (i.e., melt) each end so as to increase a diameter of the end of such a structure 55a-n to a value that is greater than the value of a diameter of a respective opening 56a-n.

[0088] The rear section 53b may be similarly, securely fashioned. For example, referring to Figure 9B, each of the deformable fastening structures 57a-n of the second molding 54b that has been received by an opening 58a-n of the shield 5 (openings 58a-n are shown under the structures 57a-n), for example, may be deformed (i.e., flattened or "mushroomed") by a heat staking process, for example, after passing through a respective opening 58a-n in order to increase a diameter of an end of such a structure 57a-n to a value that is greater than the value of a diameter of a respective opening 58a-n (i.e., the deformed end is wider than the opening) to securely fasten the rear section 53b of the shield 5 to the second molding 54b which is also connected to a ground conductors of wafer 12. As explained previously, one exemplary heat staking process may utilize a pulsed laser that heats each end of structures 57a-n to deform (i.e., melt) each end so as to increase a diameter of the end of such a structure 57a-n to a value that is greater than the value of a diameter of a respective opening 58a-n.

[0089] In an embodiment of the invention, though the inventive rigid shields may be configured geometrically different than a flexible shield, rigid shields may be similarly connected to wafer 11.

[0090] Having described exemplary flexible and rigid shields we now turn to a discussion of exemplary connections that function to connect the two shields to ground (G) conductors of a wafer.

[0091] Referring now to Figure 10A there is depicted a side view of exemplary connections of a flexible shield 4 and rigid shield 5 to a ground (G) conductor of a wafer as well as to each other. Though Figure 10A only depicts the connection of the shields 4, 5 to cantilever beam sections 120a-n and terminal end section 12a of one of ground conductor of wafer 12, it should be understood that the shields 4,5 may be similarly connected to substantially all of the ground (G) conductors of wafer 12.

[0092] In particular, the top and rear sections 53a,b of rigid shield 5 may be securely connected to cantilever beam sections 120a-n of a ground (G) conductor of wafer 12 using the combination of moldings 54a,b, deformable structures 55a,57a, openings 54a,56a (not labeled in Figure 10A) and a plurality of welds 600a to d. In an embodiment molding 54a comprises a box-like structure with an opening in the middle to allow for welding, for example.

[0093] Further, though Figure 10A depicts four welds 600a to d it should be understood that more or less welds may be utilized provided the integrity of the connection of a rigid shield to a ground conductor is achieved. Figure 10A also depicts secondary end portion 44a of flexible shield 4 configured to function to make electrical and mechanical contact with a cantilever beam section 120a of a ground (G) conductor and contact with an end 52a of rigid shield 5.

[0094] By connecting a rigid shield to the cantilever beam sections of a ground conductor, the welds function to add mechanical strength to the resulting combination of a corresponding wafer and rigid shield. Further, the welds reduce electrical resonance due to the fact that the welds, which connect multiple cantilever beam sections of a ground conductor to a rigid shield, creates a common ground stricture. Such a common ground structure functions as an electrical bridge across the connector that shields signals within conductors from electromagnetic interference and provides increased signal integrity (e.g. resonance may be improved or controlled by connecting a wafer and shield as described herein).

[0095] In embodiments of the invention, each weld 600a to d may be formed by applying a converging beam of laser light on to the weld to melt the weld to a respective cantilever beam section 120a-n and to a corresponding portion of rigid shield 5. Figure 11 depicts an illustration of a close-up view of an exemplary welding position where

an exemplary weld 600a may be created between a portion of a rigid shield and a cantilever bean section. In an exemplary embodiment, the diameter of a weld may be 0.16mm. However, it should be understood that the dimensions of a weld may vary (e.g., a 0.2mm diameter).

[0096] Referring now to Fig.10B there is depicted a cross-sectional view of the connections of a portions 500a,b of rigid shield 5 to cantilever beam portions 120b and 123b of wafers, for example. In particular, portions of rigid shield 5 are securely connected to cantilever beam portions 120b and 123b of a ground (G) conductor of wafer 12 using welds 600b, 600c, for example. To provide a desirable capacitance for transmission lines that includes cantilever beam sections 121b,122b of differential signal (S) conductors, portions 500a,b of rigid shield 5 should be a nominal distance d_2 from respective cantilever beam sections 121b,122b of signal (S) conductors and a lengthwise portion p_2 of rigid shield 5 may be configured a nominal distance d_3 from the cantilever beam sections 121b,122b of signal (S) conductors of a corresponding pair of differential signal (S) conductors. For example, in one embodiment the distances d_2, d_3 may be 0.16mm and 0.29mm (nominal), respectively, to provide acceptable capacitance.

[0097] More generally, in embodiments of the invention, portions of a rigid shield should be a nominal distance d_2 from respective cantilever beam sections of signal (S) conductors of a corresponding pair of differential signal (S) conductors and a lengthwise portion p_2 of a particular rigid shield should be a nominal distance d_3 from respective cantilever beam sections of a signal (S) of the corresponding pair of differential signal (S) conductors to provide a desirable capacitance and resulting voltage for a transmission line.

[0098] It should be understood that shield 5 is comprised of a plurality of portions p_2.

[0099] Similar to the inventive flexible shields provided by the present invention, inventive rigid shields may also affect resonance and cross-talk performance of an inventive connector 1.

[00100] In more detail, the portions p_2 may be said to create a responsive, electromagnetic cavity in the longitudinal direction of the path of a signal being conducted through a conductor of a wafer. In particular, in embodiments of the invention as the length of longitudinal portions p_2 of shield 5 are progressively shortened the resonant frequency modes that can be generated by the corresponding, resulting cavity are believed to progressively increase in frequency.

[00101] As described in more detail below, the increased proximity of mechanical welds (see welds 600a to 600d in Figure 10A) is also believed to result in a shifting of the resonant frequencies to higher frequencies within such a cavity.

[00102] Further, the inventors have discovered that the rigid shield 5 as shown in the figures and as described herein improves cross-talk between signal (S) conductors of wafers 11, 12, for example. In more detail, transverse, flexible portions of shield 5 (not shown in Figure 10B, but see Figure 8C) create a proximate Faraday cage with a near field boundary to differential signal (S) conductors of a given transmission line of wafer 12 covered by the shield 5 thereby limiting the adverse coupling of components of such an electric field to differential signal conductors of transmission lines within an adjacent wafer, such as wafer 11.

[00103] Figure 10C depicts a cross-sectional view of a portion 601 of a rigid shield 5 according to an embodiment of the invention. The portion 601 may comprise a plastic and may function to mechanically support elements of the shield 5 and connector 1 and hold such elements together. Further, the portion 601 may function to electrically insulate elements of the connector 1 from one another. More particularly, the portion 601 may be made of a dielectric material having a dielectric constant that further functions to affect the electric field between, and therefore the voltage and capacitance between: (i), signal conductors 121b, 122b, (ii) signal and ground conductors 120b, 121b and 122b, 123b and (iii) the rigid shield 5 and the underlying signal and ground conductors 120b to 123b.

[00104] While benefits, advantages, and solutions to problems have been described above with regard to specific embodiments of the present invention, it should be understood that such benefits, advantages, and solutions and any element(s) that may cause or result in such benefits, advantages, or solutions, or

cause such benefits, advantages, or solutions to become more pronounced are not to be construed as a critical, required, or an essential feature or element of any or all the claims appended to the present disclosure or that result from the present disclosure.

We claim:

1. An electrical connector comprising:

a housing; and

one or more wafers, each wafer comprising at least one flexible and at least one rigid shield, wherein lengthwise portions of each flexible shield are configured at a nominal distance from cantilever beam sections of electrical signal conductors of a corresponding pair of differential signal conductors of a transmission line for affecting an impedance of the transmission line.

2. The connector as in claim 1 comprising an octal, small form factor pluggable connector.

3. The connector as in claim 1 wherein each transmission line comprises a plurality of electrical terminal end sections of ground and signal conductors, each of the plurality of terminal end sections operable to mechanically and electrically connect the connector to an electronic module.

4. The connector as in claim 3 wherein each flexible shield comprises a self-aligning flexible shield configured to cover a first portion of each of the ground conductors.

5. The connector as in claim 1 wherein each flexible shield is configured to correspondingly flex in substantially the same direction as respective ground conductors of a respective wafer yet maintain the nominal distance from the respective signal conductors.

6. The connector as in claim 1 wherein each flexible shield comprises a metal alloy.

7. The connector as in claim 1 wherein at least one of the flexible shields comprises a copper alloy.

8. The connector as in claim 1 wherein at least one of the flexible shields comprises a non-metallic material.

9. The connector as in claim 1 wherein each flexible shield is configured to electrically connect electrical ground sections of the rigid shield to ground conductors of a respective transmission line.

10. The connector as in claim 1 wherein each flexible shield comprises secondary end portions configured to mechanically separate the lengthwise portions of the flexible shield from the cantilever beam sections.

11. The connector as in claim 10 wherein the secondary end sections comprise cantilever springs.

12. The connector as in claim 1 wherein each rigid shield is configured to operate as an electrical ground and is configured to cover a second portion of each of the electrical ground conductors.

13. The connector as in claim 1 wherein each rigid shield is configured to resist flexing in substantially the same direction as respective electrical ground conductors of a respective wafer.

14. The connector as in claim 1 wherein each rigid shield comprises a metallic material.

15. The connector as in claim 1 wherein each rigid shield is connected to respective cantilever beams of ground conductors of a respective wafer to provide mechanical support for the ground conductors.

16. The connector as in claim 1 wherein each rigid shield comprises a top and rear section, and wherein the top and rear sections are configured to align with ground conductors of a respective wafer.

17. The connector as in claim 16 further comprising a plurality of welds for connecting each respective top and rear sections to respective cantilever beam sections of ground conductors of a respective wafer.

18. A self-alignable and flexible shield for a high speed connector configured to correspondingly flex in substantially the same direction as electrical ground conductors of a transmission line of a wafer yet maintain a nominal distance from electrical differential signal conductors of the transmission line.

19. The flexible shield as in claim 18 comprising lengthwise portions configured to cover a portion of the ground conductors.

20. The flexible shield as in claim 18 further configured to maintain the nominal distance from cantilever beam sections of the differential signal conductors to affect an impedance of the transmission line.

21. The flexible shield as in claim 18 wherein the connector comprises an octal, small form factor pluggable connector.

22. The flexible shield as in claim 18 wherein the shield comprises a metal alloy.

23. The flexible shield as in claim 22 wherein the shield comprises a copper alloy.

24. The flexible shield as in claim 18 wherein the shield comprises a non-metallic material.

25. The flexible shield as in claim 18 further configured to electrically connect electrical ground sections of a rigid shield to the ground conductors of the transmission line.

26. The flexible shield as in claim 18 comprising secondary end portions configured to mechanically separate lengthwise portions of the flexible shield from cantilever beam sections of the ground conductors.

27. The flexible shield as in claim 26 wherein the secondary end portions comprise cantilever springs.
