(54) Title : TIRE TREAD HAVING IMPROVED RIGIDITY

(54) Titre : BANDE DE ROULEMENT POUR PNEU DE RIGIDITE AMELIOREE

FIG 1

(57) Abstract : The invention relates to a tread (10) including at least two wearing courses provided with at least one continuous groove (2) including a plurality of outer cavities (21) leading onto the running surface in the new condition, and a plurality of inner cavities (22) positioned radially and entirely inside the running surface in the new condition, each outer cavity (21) of a continuous groove (2) being connected to at least two inner cavities (22) of the same groove by connecting channels (23) ensuring the continuity between said inner and outer cavities, said tread further including a plurality of scorings (30) opening out onto the rolling surface of the tread in the new condition, each of said scorings connecting two consecutive outer cavities of a single groove and at least two connecting channels and at least one inner cavity.

Bande de roulement (10) comprenant au moins deux couches d'usure pourvue avec au moins une rainure continue (2) comprenant une pluralité de cavités externes (21) débouchant sur la surface de roulement à l'état neuf et une pluralité de cavités internes (22) placées radialement et en totalité à l'intérieur de l'état neuf, chaque cavité externe (21) d'une rainure continue (2) étant reliée à au moins deux cavités internes (22) de la même rainure par des canaux de liaison (23) assurant la continuité entre lesdites cavités internes et externes, cette bande comprenant en outre une pluralité d'incisions (30) s'ouvrant sur la surface de roulement de la bande à l'état neuf, chacune desdites incisions reliant deux cavités externes consécutives d'une même rainure et au moins deux canaux de liaison et au moins une cavité interne.

TYRE TREAD HAVING IMPROVED RIGIDITY

(0001) The invention relates to tyre treads and more particularly to the tread block patterns of these treads and to the tyres provided with such treads which have a more lasting ability, over time, to clear away surface water present on the road surface in rainy weather, these treads not being penalized in terms of wear rate.

(0002) As is known, the use of tyres under wet-weather driving conditions requires the water present in the region of contact between the tyre and the road surface to be cleared away as quickly as possible so as to ensure that material of which the tread is made makes contact with this road surface. Any water which is not pushed in front of the tyre flows into or is partially collected by the grooves and incisions formed in the tyre tread.

(0003) Definitions:

(0004) A tread block pattern of a tread here means the geometry of that part of the tread that is intended to come into contact with a road surface, this tread block pattern being formed by raised elements delimited from one another by cuts (grooves, incisions, wells, cavities).

(0005) A groove here means a hollow that opens onto a tread surface that comes into contact with the road surface, this hollow having a mean width that is suited to the walls of material that delimit it never coming into contact with one another under normal conditions of use of the tyre. The grooves may have any shape in cross section and in terms of the line that they follow along the tread surface and may be oriented in any direction. What is meant by the line that a groove follows along the tread surface here means the mean geometric line followed by the edges formed by the said

- 2 -

groove on the said surface. A groove may have ends that are open towards the outside of the tread or alternatively may be circumferentially continuous.

5 (0006) An incision here means a thin slit of small mean width such that, under certain loading conditions, the walls of material that delimit it can, at least partially, come into contact with one another during passage in the contact patch.

10 (0007) In the present description, the terms "radial" or "radially" are used to indicate a direction which, when considered on the tyre, is a direction perpendicular to the axis of rotation of the tyre whereas, when considered on a tread alone, it corresponds to the thickness direction of the said
15 tread. Moreover, the word "circumferential" is used to indicate a direction which corresponds to a direction tangential to a circle centred on the axis of rotation of the tyre. This same direction corresponds to the longitudinal direction of the tread, this tread being
20 formed in the manner of a flat strip before it is incorporated into a tyre.

(0008) The total volume of the hollows (or cavities) in a tread is equal to the sum of all the volumes of hollows which may or may not open onto the tread
25 surface of the tread in the as-new condition. Some of these hollows may open up onto the contact patch after the tread has become partially worn.

(0009) The total volume of a tread is equal to the sum of the total volume of material that can be worn away
30 during running before the tyre has to be removed (either in order to retread it or to replace it with a new tyre) and of the total volume of hollows.

(0010) The total thickness E of a tread corresponds to the thickness of material intended to be worn away
35 during running. By convention, this total thickness E

- 3 -

does not take into consideration any thickness that might be provided for to allow the grooves to be partially recut during the regrooving operation. This total thickness E is measured on the as-new tyre
5 between the tread surface and the external surface of the wear indicators. Radially between the crown reinforcement of the tyre and this total thickness E , there is generally an additional thickness E^* of tread.

(0011) For tyres intended for the steered or load-
10 bearing axle of a heavy goods vehicle, it is commonplace for the tread of these tyres to be provided with circumferential (or even longitudinal) grooves of a depth equal to the total thickness of the tread (this total thickness not taking into consideration any
15 thickness that may be provided for to allow the grooves to be partially recut). This groove depth as a general rule is between 13 and 18 mm on tyres intended for such axles. For tyres intended for the driven axles, the depth of the grooves may nonetheless be as much as
20 24 mm. Thus it is possible to obtain a tread which in terms of clearing away any water present on the road surface always performs better than the minimal performance known as the safety performance, and does so regardless of the level of tread wear.

25 (0012) For tyres of the prior art, the total volume of hollows is, as a general rule, between 15 and 25% of the total volume of the tread intended to be worn away during running (the total volume corresponding to the volume of material to which the said total volume of
30 hollows is added).

(0013) Further, it is found that these tyres have an effective volume of hollows V_e in the contact patch which is relatively high in the as-new condition (effective here meaning potentially capable of being
35 filled with a liquid present on the road surface). This volume of hollows opening onto the tread surface in the contact patch is, on average, of the order of 100 cm^3

- 4 -

for a tyre of 315/70 R 22.5 size. The effective volume of hollows V_e opening onto the tread surface in the contact patch is evaluated when the tyre is subject to its nominal inflation and static loading conditions as defined by the ETRTO standard.

(0014) While grooves or, more generally, cavities are essential to clearing away the water in the contact patch, the resulting reduction in tread material can have an appreciable adverse effect on the wearing performance of this tread and therefore reduce the service life of the tyre as a result of an increase in the wear rate. Other tyre performance aspects may also be detrimentally affected, particularly the handling, road noise and rolling resistance performance aspects. It is also found that these grooves that are formed so that they have a working height equal to the height of the tread that is to be worn away may be the cause of endurance problems. Under certain running conditions, foreign bodies such as stones may become lodged in these grooves and attack the bottoms of these grooves causing breaks to appear in the rubber.

(0015) Creating a plurality of grooves on a tread therefore has the disadvantage of reducing the amount of tread material for a given width of tread and therefore of reducing the service life of the tyre as a result of an increase in the wear rate.

(0016) Moreover, the grooves lower the compression and shear rigidities because these grooves delimit portions of material that are more sensitive to deformation by comparison with the portions that are delimited by incisions. This is because in the case of incisions the walls of material that delimit these incisions are able to come into contact with one another at least in the contact patch. This reduction in rigidity, where grooves are present, leads to an increase in deformations and results in a reduction in the wearing performance of the tread: greater wear is observed for

a low fixed distance covered (and this corresponds to an increase in the wear rate of the tread). Further, an increase in rolling resistance is also observed and therefore an increase in the fuel consumption of vehicles fitted with such tyres as a result of an increase in hysteresis losses associated with the deformation cycles of the material that makes up the tread.

[0017] It is an object of the present invention to provide a tread provided with grooves and with incisions that is able to have a performance the same as or better than the minimum safety performance for water clearance and for this to be true regardless of the level of tread wear while at the same time appreciably improving the performance in terms of service life to wear, reducing the rolling resistance and improving the ability of the tread to withstand attack.

[0018] In order to achieve this objective, there is proposed a tyre tread of thickness E having a tread surface intended to come into contact with a road surface, said tread including at least two wearing layers, within the thickness E, said tread being characterized in that it is provided with at least one continuous groove including a plurality of external cavities opening onto the tread surface in an as-new condition and a plurality of internal cavities placed radially and completely inside the tread surface in the as-new condition,

a first said wearing layer extending into the thickness E of the tread as far as the radially innermost points of the external cavities,

each other said wearing layer extending into the thickness E of the tread as far as innermost points of the internal cavities of the wearing layer considered,

the external cavities having a mean depth P1, a mean length L1 and a cross-sectional area S1,

the internal cavities having a mean height P2, a mean length L2 and a cross-sectional area S2,

said external and internal cavities being such that: the difference between the mean lengths of the internal cavities and of the external cavities is at most equal to 20% of the longest mean length (that is $0.80 \leq L1/L2 \leq 1.20$), the difference in the mean cross-sectional areas of the internal and external cavities is at most equal to 20% of the largest mean area (that is $0.80 \leq S1/S2 \leq 1.20$),

each said external cavity of a said continuous groove being connected to at least two said internal cavities of the same said continuous groove by connecting channels that provide continuity between the said internal and said external cavities,

said tread further including a plurality of incisions opening onto the tread surface of the tread in the as-new condition, each of said incisions connecting two consecutive said external cavities of one and the same said continuous groove and at least two said connecting channels and at least one said internal cavity, and in that each said connecting channel has two ends each having cross-sectional areas equal to the cross-sectional areas of the internal and external cavities that are connected by said connecting channel.

[0019] In this application a wearing layer means part of the tread connected to the maximum depth of the grooves in the said wearing layer. A wearing layer has a thickness which is less than the total thickness of the tread and which is equal to the maximum depth of

- 6 -

the grooves or cavities present in this wearing layer. The treads of the invention comprise at least two wearing layers, some of the grooves or cavities of which are formed only in one of the said layers. It is
5 of course possible and even advantageous that, in this configuration, each wearing layer becomes active before a previous wearing layer is completely worn away; in such a case, there is an overlap between at least two wearing layers. A wearing layer becomes active as soon
10 as the cavities or grooves formed within this layer open onto the tread surface of the tyre in contact with the road surface to clear away the water present on the said road surface in wet weather. The first wearing layer corresponds to that part of the tread that is
15 radially nearest to the outside in the as-new condition.

(0020) The first wearing layer extends, in the tread surface in the as-new condition, into the thickness of the tread as far as the radially innermost points of
20 the external cavities. Radially innermost is to be understood as meaning the points most distant from the tread surface in the as-new condition.

(0021) After this first wearing layer there is another wearing layer defined as being the layer extending into
25 the thickness of the tread as far as the radially innermost points of the internal cavities of the other wearing layer considered. This layer extends from the radially outermost points of the internal cavities.

(0022) The external cavities have a mean depth $P1$ less
30 than the total thickness E of the tread, a mean length $L1$ and a cross section, in a plane of section perpendicular to the tread surface, of area $S1$ (these preferred arrangements apply to all the variants described in this document).

35 **(0023)** The internal cavities have a mean height $P2$ less than the total thickness E of the tread (this

- 7 -

height being measured between the radially outermost points and the radially innermost points of the walls delimiting the said cavities), a mean length L_2 and a cross-sectional area S_2 (these preferred arrangements
5 apply to all the variants described in this document).

(0024) All these cavities of one and the same continuous groove are such that the difference between the mean lengths of the internal cavities and of the external cavities is at most equal to 20% of the
10 longest mean length (i.e. $0.8 \leq L_1/L_2 \leq 1.2$), and the difference in the mean cross-sectional areas of the internal and external cavities is at most equal to 20% of the largest mean area (i.e. $0.8 \leq S_1/S_2 \leq 1.2$).

(0025) Furthermore, each external cavity of a continuous groove is connected to at least two internal
15 cavities of the same groove by connecting channels that provide continuity between the said internal and said external cavities. Each connecting channel has two ends connected to an internal cavity on the one hand and to
20 an external cavity on the other; each connecting channel has cross sections (in a plane of section perpendicular to the mean direction of the groove) the areas of which are respectively equal to the cross-sectional areas of the internal and external cavities
25 that are connected by this connecting channel.

(0026) This tread further comprises a plurality of incisions opening onto the tread surface of the tread in the as-new condition, each of the said incisions connecting two consecutive external cavities of one and
30 the same groove and at least two connecting channels and at least one internal cavity.

(0027) Thanks to the presence of these connecting cavities it is possible to ensure that water circulates from an external cavity to an internal cavity of one
35 and the same groove thus better clearing away the water

- 8 -

in the contact patch while at the same time reducing hydrodynamic head losses.

(0028) Each layer has a thickness at most equal to 75% of the total thickness E of the tread (each wearing
5 layer comprising grooves or cavities that are specific to it and which are not to be found in their entirety in some other layer).

(0029) Advantageously, the thickness of the tread radially on the outside of each internal cavity is
10 greater than 25% of the total thickness E of the tread.

(0030) The external cavities and the internal cavities preferably have mean depths at most equal to 75% of the total thickness E of the tread.

(0031) Thanks to this tread structure, a volume of
15 hollows is obtained that is suitable for satisfactorily clearing away water while at the same time limiting the reduction in rigidity of the tread in the as-new condition, this volume of hollows being formed by the external cavities in a first phase of use and then by
20 just the internal cavities in another phase of use, these internal and external cavities being connected to one another by connecting channels. The groove according to the invention can be likened to a continuous groove that opens regularly and
25 discontinuously onto the tread surface of the tread in the as-new condition. This groove may adopt a wavy overall shape intersecting the tread surface in the as-new condition. It is the presence of rubbery material radially on the outside of the internal cavities and
30 radially on the inside of the external cavities that increases the rigidity of the tread, particularly in terms of compression.

(0032) By reducing the level of hollows at the surface in the as-new condition, the tread according to the
35 invention also has the advantage of being less

- 9 -

sensitive to the retention of stones and therefore offers better resistance to breakage at the bottom of the grooves which breakages are caused by the penetration of stones into the rubbery material. What
5 is meant here by the level of hollows at the surface is the ratio between the surface area of the external cavities open on the tread surface and the total surface area of the said tread. The fact that the internal cavities of one and the same groove do not
10 open onto the tread surface in the as-new condition effectively makes it possible to reduce the level of hollows in the as-new condition, while at the same time having effective water clearance in the groove.

(0033) For preference, the tread according to the
15 invention is such that internal cavities are arranged within the thickness of the tread to become open to the outside when the tread partially worn, this partial wear being less than the total wearing away in the first wearing layer. What is meant by partial wear that
20 is less is that the reduction in thickness of the tread as a result of wear is less than the reduction in thickness corresponding to the wear in the first layer, i.e. corresponding to the disappearance of the external cavities. In this advantageous configuration it is said
25 that the distance of overlap between the wearing layers is positive.

(0034) For preference, this distance of overlap between the wearing layers is less than half the depth P1 of the first cavities.

30 (0035) This variant has the advantage of ensuring a near-constant working volume of hollows for clearing away water present in the contact patch, regardless of the level of tread wear.

(0036) For preference, the tread according to the
35 invention is such that each connecting channel connecting an external cavity to an internal cavity of

- 10 -

one and the same groove has a length L_i greater than zero and less than the circumferential length L_1 of the external cavities. (L_i measures the shortest length in the circumferential direction between one end of the external cavity and one end of the internal cavity).
5 For preference, the length L_i of each connecting channel is greater than zero and at most equal to 50% of L_1 .

(0037) In a variant of the invention, the tread is
10 such that the internal and external cavities of two successive wearing layers of one and the same groove do not overlap - completely or in part - in the direction of the thickness of the tread, i.e. that they are entirely offset from one another in the mean direction
15 of the groove. The mean direction of a groove corresponds to the direction in which the groove allows the water to flow when running over a wet road surface; this direction in general corresponds to the direction of largest dimension of the groove.

20 **(0038)** This variant whereby the internal and external cavities do not overlap - completely or in part - within the thickness has the advantage of minimizing hydrodynamic head losses in the path followed by the water from the external cavities to the internal
25 cavities. In the event of an overlap or superposition - completely or in part - of the external and internal cavities that means that one end of an external cavity is situated beyond one end of an internal cavity which is within the scope of the present invention but is
30 considered to be less favourable from a point of view of how the water flows through the groove.

(0039) According to one advantageous embodiment of the invention, the total volume of hollows is at least equal to 7% and at most equal to 12% of the total
35 volume V of the tread.

- 11 -

(0040) According to another advantageous embodiment of the invention, the effective volume of hollows V_e (in the laden state) for each wearing layer, satisfies the following relationship:

5 (0041) $0.4 Se < V_e < 0.8 Se$,

(0042) in which 0.4 and 0.8 are heights expressed in millimetres and Se is the surface area (in mm^2) delimited by the external outline of the contact patch of the tread measured under static conditions under
10 nominal load and pressure, with the tyre being fitted to the recommended rim.

(0043) The heights of 0.4 mm and 0.8 mm correspond to mean depths of water that may be present on a road surface in wet weather and that has to be cleared away
15 in order to maintain good contact between the tread and the road surface. These mean heights multiplied by the surface area Se - which surface area is determined by the outline of the contact patch of the tread on the same road surface and expressed in mm^2 (the surface
20 areas corresponding to the cavities that open onto the tread surface are taken into consideration here) - give an indication of the effective volume of cavities V_e (in the laden state). If this volume V_e is less than 0.4 times Se , it is not enough to obtain satisfactory
25 water clearance. If this volume V_e is greater than 0.8 times Se then it is deemed excessive from the standpoint of obtaining suitable tread rigidity.

(0044) The effective volume of hollows V_e in the contact patch plays a part in draining water away from
30 the contact patch where the tread makes contact with a road surface.

(0045) In order in particular to increase the level of hollows at the surface of the tread in the contact patch (the ratio between the surface area of hollows
35 opening onto the tread surface of the tread in the as-

- 12 -

new condition, and the total surface area of the contact patch), the tread comprises at least one groove formed of a plurality of pairs of external cavities, each of which is extended by a connecting channel,
5 these connecting channels opening into one and the same internal cavity. The volume of this internal cavity can be appreciably reduced by comparison with the volume of the external cavities or adapted by those skilled in the art according to the desired performance and
10 according to the tyre concerned.

(0046) In another variant, the effective volume of hollows V_e increases with the level of wear of the tread, and therefore increases from one wearing layer to the next.

15 **(0047)** In another variant, the tread according to the invention comprises at least one groove, the external cavities of which are each extended at both ends by two connecting channels, these connecting channels each opening into separate internal cavities. Further, each
20 internal cavity, as well as the connecting channels that connect this internal cavity to two external cavities, are extended radially towards the tread surface of the tread in the as-new condition by an incision to allow the tread according to the invention
25 to be moulded and demoulded.

(0048) That which has been described for a tread comprising two wearing layers can easily be applied to a number of wearing layers greater than two and notably to three wearing layers. In such a variant, the tread
30 according to the invention comprises additional cavities situated in a third wearing layer which extends the second wearing layer radially on the inside. These additional cavities are connected to the internal cavities of the second wearing layer by
35 additional connecting channels. These additional cavities determine a third level of wear and open onto the tread surface after tread wear has practically worn

- 13 -

away the second cavities. One application of this variant is particularly advantageous for tyres that have very thick treads.

(0049) The continuous grooves formed of a succession
5 of external and internal cavities connected by connecting channels, that form the subject of the invention, can be oriented in any direction along the tread or along the tyre (i.e. longitudinally or transversely or obliquely in relation to one or other
10 of these directions).

(0050) Advantageously, grooves according to the invention are directed essentially in a direction corresponding to the largest dimension of the tread: whether that is the longitudinal direction of the tread
15 or the circumferential direction when this tread is fitted to a tyre.

(0051) In one particularly advantageous variant, a tread according to the invention comprises a first plurality of continuous grooves according to the
20 invention in a first direction and a second plurality of continuous grooves according to the invention in a second direction that intersects the first direction to form a network of criss-cross grooves. Advantageously, these first and second pluralities of grooves according
25 to the invention are arranged in such a way that the internal cavities of these first and second pluralities of grooves are interconnected in order to enhance the criss-cross grid effect. What is meant by interconnected is that it is possible for fluid to
30 circulate between the various internal cavities of the two pluralities of grooves.

(0052) In an advantageous variant, a tread according to the invention comprises a first plurality of grooves according to the invention in a first direction and a
35 second plurality of grooves according to the invention in a second direction that intersects the first

- 14 -

direction to form a network of continuous criss-cross grooves. These first and second pluralities of grooves according to the invention can be arranged in such a way that the internal cavities of these first and second pluralities of grooves are located at different depths so as, in this case, to obtain a level of hollows that remain substantially constant irrespective of the level of tread wear. What is meant by level of hollows is the ratio between the surface area of hollows on the tread surface considered and the total surface area of the tread at the wear level considered. The internal cavities, even though they are connected to external cavities, are not considered to contribute to a tread surface level of hollows until they appear on a new tread surface once the tread has become worn.

(0053) In another variant, it is possible to plan for the presence of at least one channel directed in a direction parallel to the mean direction of a continuous groove formed of a succession of internal and external cavities, this channel being situated at a depth corresponding to that of the internal cavities of the said groove and this channel being extended by an incision either towards the tread surface of the tread or towards the internal surface of the said tread. What is meant by the internal surface of a tread is the surface via which the tread is in contact with the tyre to which it is fitted. These incisions and channels may easily be produced when the tread is being moulded. The cross section of this channel is determined so that when the channel opens onto the tread surface following tread wear, a new groove is formed of a cross section suited to correct flow of the water present on the road in wet weather. This channel is designed to form a new groove by opening onto the tread surface after partial wear that is at most equal to the thickness of the first wearing layer.

- 15 -

(0054) In this variant, the tread may further comprise means for placing at least one channel in communication with a plurality of internal cavities of a continuous groove. Thus the ability to clear away water when
5 driving on a wet road surface is improved, at least after a part-wear condition that sees the channel open onto the tread surface, and form a new groove.

(0055) In order to maintain a satisfactory level of rigidity of the tread according to the invention it is
10 advantageous for the incisions that extend the internal and external cavities to be provided with means of mechanically blocking relative movement of the opposing walls that delimit the said incisions. Such means may adopt the form of a waviness of the opposing walls or
15 alternatively of reliefs moulded onto the said walls and suitable for engaging with one another.

(0056) The invention also relates to a tyre provided with a tread defined according to the invention, this tread radially on the outside surmounting a tyre cover
20 consisting of a carcass reinforcement and of a crown reinforcement. The tread of this tyre is produced as in one of the preceding variants, certain dimensions of the grooves being connected with the mean length of the contact patch of the tread under nominal conditions of
25 use of the tyre, these nominal conditions of use being defined in the ETRTO or JATMA standards.

(0057) It is advantageous that, for each circumferentially oriented groove formed of cavities opening onto the tread surface and of cavities under
30 the tread surface, there be at least one external cavity always in the contact patch in order to allow water clearance. If the mean length of the contact patch under nominal conditions of use of the tyre provided with a tread according to the invention is
35 denoted T (this mean length being obtained by dividing the total surface area delimited by the external outline of this contact patch by the width W of the

- 16 -

said surface area), it is more preferable still for the mean length of these external cavities of the circumferential grooves to be between 25% and 75% of the mean length T of the contact patch.

5 (0058) In a variant that has not been depicted, the tread comprises a plurality of grooves which are formed of a plurality of external cavities and of internal cavities connected by connecting channels oriented in the longitudinal direction of the tread, these grooves
10 being arranged in such a way that the external cavities that open onto the tread surface in the as-new condition are arranged offset from one another and so that the internal cavities are also arranged so as to all be offset from one another. The advantage of such
15 an arrangement is that it limits the reduction in shear rigidity of the tread notably under transverse loading (for example when cornering).

(0059) Other features and advantages of the invention will become apparent from the description given
20 hereinafter with reference to the attached drawings which, by way of nonlimiting examples, show some embodiments of the subject matter of the invention.

Description of the figures

25

(0060) Figure 1 is a partial view of the tread surface of a tread comprising a continuous groove according to the invention;

(0061) Figure 2 is a view in section on II-II taken
30 across the tread of Figure 1;

(0062) Figure 3 is a view in section on III-III taken across the tread of Figure 1;

(0063) Figure 4 is a view in section on IV-IV taken across the tread of Figure 1;

- 17 -

(0064) Figure 5 is a cross section of an embodiment variant whereby a continuous channel situated entirely under the tread surface is provided;

5 (0065) Figure 6 is a partial view of a tread according to the invention in the as-new condition;

(0066) Figure 7 is a plan view of the tread surface of the tread of Figure 6;

10 (0067) Figure 8 is a plan view of the tread surface of the tread of Figure 7 following tread wear down to the second wearing layer;

(0068) Figure 9 is a partial view of a variant of a continuous groove having a pair of external cavities connected to one internal cavity;

15 (0069) Figure 10 is a partial view of a variant of a continuous groove having one external cavity connected to two internal cavities;

20 (0070) Figure 11 is a partial view of a variant whereby a tread is provided with grooves according to the invention oriented in two intersecting directions, these grooves being interconnected;

25 (0071) Figure 12 shows a variant of the invention whereby the incisions that connect the internal cavities and the connecting channels to the tread surface are provided with wells that open onto the tread surface;

(0072) Figure 13 is a cross section through a variant of tread according to the invention in which the inclinations of the connecting channels at the ends of an internal cavity are different;

30 (0073) Figure 14 shows a variant whereby the grooves and incisions follow wavy paths;

- 18 -

(0074) Figures 15a and 15b show a variant whereby the external cavities of one and the same continuous groove are extended towards the inside of the tread by an incision provided with blocking means;

5 (0075) Figure 16 shows a variant of tread comprising three wearing layers;

(0076) Figure 17 shows another variant of tread comprising three wearing layers; and

10 (0077) Figure 18 shows a variant of a tread comprising, in addition to the continuous grooves formed of a succession of external and internal cavities, transverse channels opening onto the outside of the tread and connected to internal cavities of the continuous grooves.

15 (0078) To make the figures easier to study, the same reference symbols are used to describe variants of the invention when these reference symbols refer to elements of a similar nature, whether this be a structural or even a functional one.

20 (0079) Figure 1 shows part of a tread 10 in the as-new condition, this tread having a thickness E, a tread surface 11 intended to come into contact with the road surface during running and a surface 12 defining the thickness of the tread and situated on the opposite
25 side to the tread surface 11. This part of the tread comprises a continuous groove 2 according to the invention. The groove 2 is formed of a succession of a plurality of external cavities 21 of elongate shape of length L1 opening onto the tread surface 11 in the as-
30 new condition, and of a plurality of internal cavities 22 of length L2 situated completely within the tread in the as-new condition. Connecting channels 23 are formed to connect the internal cavities 22 and the external cavities 21 and thus ensure the continuity of the
35 groove 2 in the main direction of the groove. These

- 19 -

connecting channels 23 have a length L_i measured in the main direction of the groove. In order to ensure that liquid flows correctly between the internal and external cavities, the connecting channels have one end
5 connected to an external cavity, this end having a cross section equal to the cross section of the said external cavity. These same connecting channels have another end connected to an internal cavity, this other end having a cross section equal to the cross section
10 of the said internal cavity. In this particular instance, the cross sections of the external and internal cavities are substantially the same and each connecting channel maintains substantially the same cross section from one of its ends to the other. Of
15 course, this cross section could be modified and varied between the two ends.

(0080) With a groove 2 according to the invention everything is as if there were a tread with two wearing layers I and II taking over from one another during use
20 of the tread, each wearing layer having different cavities on the tread surface. A first layer I sees the appearance of the external cavities 21 on the tread surface and a second layer II sees the appearance of the internal cavities 23 in turn on a new tread
25 surface. Before the internal cavities appear, the connecting channels continue to play their part and in particular to ensure the continuity of the groove.

(0081) Figure 2 is a cross section through Figure 1 on a plane of section referenced II-II in Figure 1.

30 **(0082)** This Figure 2 shows the cross section of an external cavity 21 of an area S_1 and extending into the tread over a depth P_1 equal to around 74.5% of the total thickness E of the tread (this thickness corresponding to the thickness that can be worn away
35 during running).

- 20 -

(0083) This external cavity 21 is extended on each side by connecting channels 23 connecting it to internal cavities 22 visible in cross section in Figure 3.

5 (0084) Figure 3 is a cross section of Figure 1 on a plane of section referenced III-III in Figure 1.

(0085) This figure 3 shows the cross section of an internal cavity 21 of an area S2 substantially equal to the area S1 of the external cavities 21 and extending
10 towards the tread surface by an incision.

(0086) This internal cavity 22 has dimensions comparable with those of the external cavities 21; the respective lengths L1 and L2 (see Figure 4) of the external and internal cavities are substantially equal
15 here. In order for the tread always to have grooved elements on its tread surface regardless of the degree of tread wear it is advantageous, as is the case here, for the internal cavities 22 of one and the same groove 2 to appear before the external cavities 21 have
20 completely disappeared. This then forms a first wearing layer I extending between the tread surface of the tread in the as-new condition and the innermost points of the external cavities 21; a second layer extends as far as the points of the internal cavities 22 that are
25 nearest to the inside of the tread. Of course, it is possible to plan for the second cavities to appear only after the first ones have been completely worn away.

(0087) Figure 4 is a cross section through Figure 1 on a plane of section referenced IV-IV in Figure 1.

30 (0088) This Figure 4 identifies the succession of external cavities 21 and of internal cavities 22 which are joined together by connecting channels 23 of length Li. Moreover, an incision 30 that in the as-new condition opens onto the tread surface 11 connects one
35 internal cavity 22, two connecting channels 23 and two

- 21 -

external cavities 21. This incision 30 is positioned in the tread so that it opens onto the tread surface 11 in the as-new condition to make the groove according to the invention easier to mould and demould. Of course,
5 provision could be made for this incision to open onto the face 12 of the tread which is the opposite face to this tread surface 11: in this case, the tread with its grooves and incisions would need to be moulded before it was combined with a casing to form a tyre.

10 **(0089)** When the first wearing layer I is completely worn away, the initially internal cavities 22 open onto the new tread surface and, given the remaining height of tread that can be worn away may sometimes be enough to act as a reservoir for any water present on the road
15 surface.

(0090) Everything is as if the groove 2 followed a wavy line in the radial direction (i.e. in the thickness of the tread), this groove comprising a succession of parts (external cavities) that open onto
20 the tread surface in the as-new condition alternating with the parts (internal cavities) that are entirely within the tread in the as-new condition, the connecting cavities providing continuity between the volumes of the said internal and external cavities
25 (i.e. allowing fluid to flow from the outside inwards and vice versa). Thus, as the contact patch makes contact with the road surface, water present on this road surface can be cleared away by the external cavities towards the internal cavities. It is of course
30 necessary that there will always be at least one external cavity completely or partially open in the contact patch. The dimensions of the external cavities and those of the internal cavities are determined so as to meet this condition for a given length of contact
35 patch.

(0091) This same Figure 1 shows the presence of a wear indicator TWI which fixes the total thickness of tread

- 22 -

that can be worn away during running. This tyre wear indicator is moulded into the bottom of an internal cavity 22 and has a height equal in this instance to 1.6 mm in order to comply with the legal requirements.

5 **(0092)** By virtue of these arrangements, it is possible in the as-new condition to have an overall rigidity that is higher than can be achieved with the usual grooves each of which would have a total depth equal to the distance from the innermost points of the internal
10 cavities to the tread surface in the as-new condition. At least during the initial part of tread wear (i.e. until 75% of the depth of the external cavities has been worn away), the function of clearing away and collecting water is performed by this groove because
15 the water collected in the external cavities can run into the connecting channels and the internal cavities. The water thus cleared away can then re-emerge via another external cavity. Advantageously, the connections between the various cavities are suitable
20 to not detract from the flow of fluid within the groove.

(0093) When the first wearing layer I has been completely worn away, the internal cavities 22 open over their entire length onto the tread surface and can
25 then act as reservoirs to hold some of the water present on the road surface.

(0094) However, it is then advantageous, as Figure 5 shows, to combine with this groove the presence of a continuous channel 40 with an overall orientation the
30 same as or substantially the same as that of the groove 2 and the function of which is to form a new continuous groove which appears and opens onto the tread surface following partial wear such that the internal cavities 22 of the second wearing layer II have also appeared on
35 the said new tread surface. The function allowing the water to flow is then preserved because the channel 40 has become a continuous groove capable of clearing away

- 23 -

the water and allowing it to flow out, the internal cavities 22 of the groove 2 according to the invention forming water holding reservoirs which in this variant are discontinuous from one another.

5 **(0095)** This Figure 5 which is a cross section through a portion of a tread according to the invention, shows the presence of a groove 2 comprising a plurality of external cavities 21 and of internal cavities 22 which are connected by connecting channels 23, and that of a
10 channel 40, the cross sectional area of which is suited to allowing water to flow as soon as a new groove is formed following partial wear of the tread corresponding to the depth at which the channel 40 begins to appear on the new tread surface.

15 **(0096)** For preference, the channels formed within the tread are sized to offer a suitable water clearing volume and, in particular, these channels may have heights substantially equal to the height of the internal cavities. In this variant, it is possible to
20 keep the working volume of hollows for clearing water away from the road surface near-constant or even constant and to do so throughout the service life of the tyre provided with a tread as described.

25 **(0097)** Continuous grooves formed of a plurality of internal cavities and of external cavities according to the invention may be oriented in any direction in a tyre tread.

30 **(0098)** Grooves that are continuous and wavy in the thickness according to the invention may be formed in a tread such that they do not open onto the tread surface in the as-new condition but only after the tread has become partially worn. Of course, it is sensible to combine these with:

- 24 -

(0099) - either shallow grooves, which progressively become replaced with the grooves according to the invention

5 (00100) - or grooves according to the invention which in the as-new condition of the tread open onto the tread surface.

10 (00101) A degree of overlap a between the external and internal cavities is provided so that after partial tread wear, the internal cavities open onto the tread surface before the external cavities completely disappear.

(00102) Another embodiment of a tyre of 315/70 R 22.5 size comprising a tread according to the invention is now given.

15 (00103) Figure 6 depicts just part of this tread, the longitudinal direction of which is indicated by the direction of the axis XX' in this figure. This tread is of width W equal to 258 mm and has a total thickness E equal to 9.4 mm measured as being the distance
20 separating the tread surface of the tyre in the as-new condition from the wear indicators (these tyre wear indicators are positioned in such a way as to indicate a groove height of 1.6 mm). Moreover, an additional thickness E* (here equal to 6.6 mm) is provided between
25 the tread and the tyre crown reinforcement. This tread is provided with three continuous grooves 2 of longitudinal orientation (i.e. oriented circumferentially once this tread has been incorporated into a tyre), each of these grooves being formed of a
30 succession of external 21 and internal 22 cavities, the external cavities 21 opening onto the tread surface 11 of the tread in the as-new condition and the internal cavities 22 being formed completely under the tread surface in the as-new condition.

- 25 -

(00104) Connecting channels 23 connect the external cavities to the internal cavities. Each connecting channel has an end of an area equal to the cross-sectional area of the external cavity to which it is connected and at its other end of an area equal to the cross-sectional area of the internal cavity to which it is likewise connected. All these continuous grooves 2 have their main direction substantially oriented in the longitudinal direction of the tread. Alternatively, connecting channels of cross-sectional area smaller than the cross-sectional areas of the internal or external cavities may likewise be used.

(00105) In this particular instance, the length L_1 of each external cavity is equal to 150 mm and the length L_2 of each internal cavity is equal to 110 mm; the length L_i of the connecting channels is equal to 15 mm.

(00106) Each external cavity 21 has a mean width equal to 12 mm and a depth of 7 mm (i.e. 74.5% of the total thickness E). The walls delimiting an external cavity may be a mean angle of 15 degrees with a perpendicular to the tread surface and tend to converge towards one another in the direction towards the bottom of the said cavity.

(00107) Each internal cavity has a mean width equal to 9 mm and a depth of 7 mm (i.e. 74.5% of the total thickness E). The walls delimiting an internal cavity may be a mean angle of 15 degrees with a perpendicular to the tread surface and tend to converge towards one another in the direction towards the bottom of the said cavity.

(00108) Moreover, the internal cavities 22 and the connecting channels 23 are extended towards the tread surface by incisions 30 of which the delimiting walls are provided with recessed and raised patterns that engage with one another to limit as far as possible any relative movement between the said walls and thus

- 26 -

maintain greater rigidity. In this particular instance, the mean distance separating the opposing walls of one and the same incision is equal to 0.4 mm. It is noted that the external cavities 21 have substantially the same dimensions and that they are arranged so as to be offset from one another in the longitudinal direction so as to reduce the impact that they have on road noise and increase the efficiency with which they pick up water when driving over wet ground.

10 **(00109)** An overlap equal to 3 mm is provided between the external cavities and internal cavities so that following partial tread wear, the internal cavities open onto the tread surface before the external cavities completely disappear.

15 **(00110)** Figure 7 is a plan view of the tread surface of the tread of Figure 6 when the first wearing layer in contact with the road surface is present. It may be seen that the tread surface comprises three continuous grooves oriented circumferentially and intercalated axially between them two incisions extended radially inwards by a circumferentially continuous channel 40.

(00111) This tread has a total volume of hollows V_c equal to 9% of a volume equal to the sum of the total volume V of material of the tread and of the total volume of hollows.

(00112) Each wearing layer of this tread has an effective total volume of hollows V_e in the contact patch which is equal to 40 cm^3 . This effective volume V_e , expressed in mm^3 , satisfies the relationship $0.4 St < V_e < 0.8 St$ (we have $24120 < 40000 < 48240$), the surface area St being expressed in mm^2 . In this instance, the surface area St is equal to 60300 mm^2 , this surface area being delimited by the external outline of the contact patch of the tread measured under static conditions under nominal load and

- 27 -

pressure, with the tyre being fitted on the recommended rim.

5 (00113) Figure 8 is a plan view of the tread surface of the tread of Figure 6 when the tread has worn down to the second wearing layer. It shows the internal cavities which have opened onto the tread surface and are discontinuous from one another and new circumferential grooves formed by the appearance of the channels on the tread surface.

10 (00114) In another advantageous variant of the invention, at least one groove is as partially shown in Figure 9, i.e. at least one continuous groove 2 is formed of a plurality of external cavities 211, 212 opening onto the tread surface 11 in the as-new condition, these external cavities 211, 212 being
15 formed in pairs, each pair of first cavities being extended by connecting channels 231, 232 respectively, the latter connecting channels meeting to open into one and the same first end of an internal cavity 22 formed
20 within the tread. This internal cavity is extended at its second end by two connecting channels connected to a further pair of first cavities opening onto the tread surface in the as-new condition of the tread. Just like
25 in the variant discussed in relation to Figure 1, the connecting channels and the internal cavities are extended towards the tread surface by an incision, the ends of which locally on the tread surface form a Y-shaped line.

30 (00115) This variant gives a better distribution of the external cavities that open onto the tread surface of the tread in the as-new condition.

(00116) In another advantageous variant of the invention, at least one groove 2 is as partially shown in Figure 10. In this variant, a groove 2 is formed of
35 a plurality of external cavities 21 that open onto the tread surface 11, each external cavity being extended

- 28 -

- by two connecting channels 231, 232, each connecting channel opening at one end into an internal cavity 221, 222. In this variant, the number of internal cavities is therefore twice the number of external cavities.
- 5 This variant, for a water clearance volume chosen according to the desired result that a tyre is to achieve, makes it possible to obtain a more even distribution of the internal hollows within the tread and therefore less of an impact on the rigidity of the
- 10 tread. Incisions 301, 301, extend the internal and connecting cavities towards the tread surface 11. Each cavity of the pair of internal cavities may be situated at one and the same depth with respect to the tread surface 11 or may be situated at different depths.
- 15 **(00117)** In another advantageous variant of the invention which is shown with the support of Figure 11, a tread is provided with a first plurality of longitudinally directed grooves 2' (i.e. grooves that run circumferentially on the tyre provided with this
- 20 tread) and with a second plurality of grooves 2'' oriented to intersect the first plurality of grooves 2'. In this particular instance, the angle formed by these pluralities of grooves is equal to 90°, but it is quite clearly possible to use any other value.
- 25 **(00118)** Each groove 2' of the first plurality of grooves is formed of a plurality of internal cavities 22' and of external cavities 21' which are connected by connecting channels 23' defining a first wearing layer and a second wearing layer of the tread.
- 30 **(00119)** Each groove 2'' of the second plurality of grooves is formed of a plurality of internal cavities 22'' and of external cavities 21'' which are connected by connecting channels 23''. The arrangement in the variant shown is such that the position within the
- 35 thickness of the tread is substantially identical for the internal cavities of the first and second grooves 2' and 2''.

- 29 -

(00120) Further, the first and second grooves 2', 2''
interconnect at their internal cavities 22' and 22''.
The internal cavities intersect one another to form a
network of cavities both on and beneath the tread
5 surface, said network greatly favouring the clearance
of water.

(00121) Moreover, the internal cavities and the
connecting channels are extended towards the tread
surface by incisions 30' and 30'' which intersect and
10 which at their intersections have a kind of well of
circular section 50. These wells 50 have the advantage
of increasing the amount of water that the tread can
clear away when running over wet ground.

(00122) In a variant that has not been depicted, the
15 first and second pluralities of grooves 2', 2'' are not
necessarily directed so that they are perpendicular to
one another. Thus there may be a first plurality of
grooves oriented in the circumferential direction and a
second plurality of grooves oriented in a direction
20 that makes an angle other than 90° to the first
plurality of grooves. It is also possible to conceive
of a variant that further comprises a third plurality
of grooves oriented notably, although not necessarily,
symmetrically in relation to the second plurality of
25 grooves 2'' about the first plurality of grooves 2'.

(00123) In another variant that has been depicted in
Figure 12, there is a groove 2 according to the
invention that appears on the tread surface after the
tread has been partially worn, i.e. the external
30 cavities 21 do not open onto the tread surface in the
as-new condition. Moreover, the external cavities 21,
the connecting channels 23 and the internal cavities 22
are extended towards the tread surface by an incision
30 which is itself provided with a plurality of
35 widenings 61 and 62. Widenings 61 are formed towards
the outside of the external cavities 21 and widenings
62 are formed towards the outside of the internal

- 30 -

cavities 22 so as to supplement and increase the water clearing effect of the groove 2. These widenings are, in this instance, oriented substantially perpendicular to the tread surface; they could be inclined by an angle other than 90° to this surface as need be. These widenings here have the form of cylindrical wells.

(00124) Figure 13 shows another variant which is beneficial for creating a directional effect in the flow of water running along inside the groove during the running of a tyre provided with a tread itself provided with at least one continuous groove formed of a plurality of external cavities 21 and internal cavities 22 connected by connecting channels 231, 232.

(00125) In this variant, the connecting channels 233, 234 situated one each side of an internal cavity 22 have different respective lengths L_i , L_j and therefore have mean inclinations A_1 and A_2 which are different (these angles A_1 and A_2 are measured with respect to a direction perpendicular to the tread surface). In the preferred variant, the connecting channel that is most steeply inclined with respect to a perpendicular to the tread surface (i.e. the longest channel) is situated on the side that is first to come into contact with the road surface (the arrow R indicates the direction of rotation). Through this contrivance a tread block pattern is created that has a preferred direction of running (a visible means may be affixed to the tread or to the tyre to indicate this preferred direction).

(00126) In the variant depicted in Figure 14, which is fairly similar to the variant depicted in Figures 6, 7 and 8, a tread comprises, in the as-new condition, a plurality of continuous grooves of longitudinal orientation, these grooves 2 being formed of a succession of internal cavities 22 and of external cavities 21 connected by connecting channels 23. To improve the longitudinal grip, these grooves 2, on the tread surface 11, follow a pattern of wavy overall

- 31 -

shape. There may also be seen, in the variant depicted, the presence of holes formed on each incision situated between two successive external cavities; these holes extend from the tread surface to the internal cavities

5 22. Further, the tread comprises a longitudinal incision 40 which likewise has a wavy overall shape substantially parallel to the shape of the grooves 2; this incision 40 is extended into the thickness of the tread by a channel as described earlier and intended to

10 appear on the tread surface to form a new groove once the tread has been partially worn.

(00127) In the variant depicted with this Figure 14, each (first or second) cavity has a curved shape, but the person skilled in the art would be able to choose

15 any other geometric shape, notably a straight or zig-zag shape.

(00128) Figures 15a and 15b partially show a tread characterized in that each external cavity 21 opening onto the tread in the as-new condition is extended

20 radially inwards by an incision 80 as far as the bottom of the wearing part of the tread. Figure 15 shows a three-dimensional and perspective view of part of the tread according to the invention and comprising a groove 2 that is continuous and passes from the tread

25 surface 11 in the as-new condition to a wearing layer situated on the inside of the tread. This groove comprises external cavities 21 connected by channels 23 to internal cavities 22. In this variant, the external cavities 21 are extended towards the inside of the

30 tread by an incision 80, the walls of which are provided with means 82 that allow relative movement of the said walls with respect to one another to be blocked. Furthermore, it is locally provided with a widening 81 that combines with the incision 80. The

35 provisions here are the same as those made with the incision 80 situated under the external cavity; blocking means 32 are provided on the incision 30

- 32 -

opening onto the tread surface, this incision connecting together two external cavities 21 and two connecting channels 23. Figure 15b shows that same part of the tread in plan view, the surface of the drawing
5 corresponding to the tread surface. This incision 30 that opens onto the tread surface further comprises a widening 31 at its middle.

(00129) The benefit of this variant is that it improves the flattening-out of the tread in the contact patch,
10 thereby reducing resultant stress levels.

(00130) All the variants described hitherto show treads comprising two wearing layers through which the grooves according to the invention pass.

(00131) In the variants that follow, grooves according to the invention are depicted that delimit in fact
15 three wearing layers within the thickness of the tread (this number of three is not in any way a limit but simply an additional numerical example to supplement the description of the invention).

(00132) In a first of these variants (Figure 16), the internal and external cavities of the various levels are not superposed in the thickness of the tread: they are therefore offset from one another in the circumferential direction. In the second of these
25 variants (Figure 17), the internal cavities of the third wearing layer are superposed in the thickness with the external cavities, i.e. their position is more or less obtained by a translational movement of the external cavities through the thickness.

(00133) Figure 16 shows a continuous groove according to the invention defining three successive wearing layers in the thickness of the tread. In this variant, the continuous groove 2 comprises external cavities 21 that are open in the initial condition onto the tread
35 surface 11 and which are extended by connecting

- 33 -

channels 23 to first internal cavities 22 situated in a second wearing layer. These first internal cavities 22 being themselves extended by connecting channels 25 to second internal cavities 24 situated in a third wearing layer III. In this variant shown in Figure 16, radially underneath each external or internal cavity, there is no other internal cavity. Finally, this groove is extended radially towards the tread surface in the as-new condition by an incision 30 that makes such a groove easier to mould and to demould.

(00134) In another variant shown in Figure 17, the tread comprises three wearing layers I, II, III and the groove depicted comprises internal cavities 24 of the third wearing layer III which in the thickness direction overlap with the external cavities 21 of the wearing layer I. In the variants shown in Figures 16 and 17, the various cavities are depicted as having substantially identical dimensions; it would of course be within the competence of the person skilled in the art to adapt the lengths of the various cavities according to their position or alternatively to adapt the respective volumes of these cavities without departing from the scope of the present invention. In this variant shown in Figure 17, the internal cavities 22 of the second wearing layer II are connected to the third internal cavities 24 by connecting channels 25. To allow for moulding and demoulding, in addition to an incision 30 that opens onto the tread surface 11, there is provided an incision 35 connecting an external cavity 21 and the internal cavity 24 radially inside it, this incision 35 also connecting the connecting channels 23 and 25. Advantageously, these incisions 30 and 35 are provided with blocking means on the walls that delimit them.

(00135) In the variant shown in Figure 18, a tread according to the invention is further provided with transverse channels 70 formed under the tread surface

- 34 -

11 of the tread in the as-new condition, these
transverse channels being in appropriate number and
opening onto longitudinal grooves 2 (i.e. grooves that
are circumferential once the tread has been
5 incorporated into a tyre) and notably onto internal
cavities 22 of the said grooves. These same transverse
channels 70 are designed to open onto the external
lateral walls 13 of the tread and thus further improve
the water clearing capacity of the grooves 2 whatever
10 the state of tread wear. Thus, once the external
cavities 21 have completely disappeared through the
wearing away of the first wearing layer of the tread,
these transverse channels 70 form new transverse
grooves and ensure the continuity of flow of water from
15 the internal cavities 22 to the outside of the tread.

(00136) Of course, these transverse channels 70 may be
connected to several internal cavities 22 of several
grooves 2 in order to improve the flow of water from
all the grooves thus connected following partial wear
20 of the tread by thus creating a kind of network of
greater or lesser complexity. It is also possible to
connect these transverse channels 70 to continuous
channels oriented circumferentially and formed entirely
under the tread surface in the as-new condition (like
25 those shown in Figures 6 to 8).

(00137) Moreover, these channels 70, by appearing on
the tread surface after partial wear, increase the
level of hollows at the surface and form further
transverse edges that are of benefit in cutting into
30 the layer of water present on the road surface in wet
weather.

(00138) The invention is not restricted to the examples
described and depicted and various modifications or
additions can be made thereto without departing from
35 the scope thereof.

- 35 -

(00139) In particular, the tread according to the invention may comprise a combination of at least one groove formed of a succession of external and internal cavities, these opening onto the tread surface only
5 once said tread has been partially worn, and at least one additional groove that opens onto the tread surface in the as-new condition, this additional groove having a depth at least equal to that of those points of the grooves according to the invention that are nearest to
10 the inside of the tread.

(00140) The internal cavities of various grooves according to the invention may be positioned at different levels within the thickness of a tread.

(00141) Further, while the present description has been
15 entirely devoted to describing application to a tyre intended to be fitted to a heavy goods vehicle, it should be understood that a tread comprising a tread pattern also forms part of the invention because such a tread is intended to be incorporated into a tyre
20 (either at the time of manufacture or when retreading the said tyre).

(00142) In contrast with the invention, the cavities moulded using the moulding element described in the application (WO 02/38399), although they do indeed
25 define different wearing layers, they do not exhibit any true continuity between the external cavities and the internal cavities because there is no connecting channel between them allowing water to flow when running on a wet road surface.

(00143) These tread patterns according to the invention, while offering satisfactory water clearance in the contact patch throughout the service life, allow a high overall rigidity to be maintained as compared with conventional tread patterns and thus make it
30 possible to reduce the thickness of the tread for the same overall performance, and this is, of course,
35

- 36 -

favourable in terms of energy consumption. That also allows the use of suitable rubber compounds.

THE CLAIMS DEFINING THE INVENTION ARE AS FOLLOWS:

1. A tyre tread of thickness E having a tread surface intended to come into contact with a road surface, said tread including at least two wearing layers, within the thickness E, said tread being characterized in that it is provided with at least one continuous groove including a plurality of external cavities opening onto the tread surface in an as-new condition and a plurality of internal cavities placed radially and completely inside the tread surface in the as-new condition, a first said wearing layer extending into the thickness E of the tread as far as the radially innermost points of the external cavities, each other said wearing layer extending into the thickness E of the tread as far as innermost points of the internal cavities of the wearing layer considered, the external cavities having a mean depth P1, a mean length L1 and a cross-sectional area S1, the internal cavities having a mean height P2, a mean length L2 and a cross-sectional area S2, said external and internal cavities being such that: the difference between the mean lengths of the internal cavities and of the external cavities is at most equal to 20% of the longest mean length (that is $0.80 \leq L1/L2 \leq 1.20$), the difference in the mean cross-sectional areas of the internal and external cavities is at most equal to 20% of the largest mean area (that is $0.80 \leq S1/S2 \leq 1.20$), each said external cavity of a said continuous groove being connected to at least two said internal cavities of the same said continuous groove by connecting channels that provide continuity between the said internal and said external cavities, said tread further including a plurality of incisions opening onto the tread surface of the tread in the as-new condition, each of said incisions connecting two consecutive said external cavities of one and the same said continuous groove and at least two said connecting channels and at least one said internal

cavity, and in that each said connecting channel has two ends each having cross-sectional areas equal to the cross-sectional areas of the internal and external cavities that are connected by said connecting channel.

5 2. A tread according to Claim 1, characterized in that the depths of each said internal or said external cavity is less than the total said thickness E of the tread.

10 3. A tread according to Claim 1 or Claim 2, characterized in that the distance a between each said internal cavity and the tread surface of the tread in the as-new condition is greater than 25% of the total thickness E of the tread.

4. A tread according to any one of Claims 1 to 3, characterized in that each said wearing layer has a thickness at most equal to 75% of the total thickness E of the tread.

15 5. A tread according to any one of Claims 1 to 4, characterized in that the internal cavities are arranged within the thickness E of the tread to become open when the tread is partially worn by less than a total wearing away of the first wearing layer.

20 6. A tread according to any one of Claims 1 to 5, characterized in that each said connecting channel connecting a said external cavity to a said internal cavity of one and the same said continuous groove has a length L_i of greater than zero and less than half the length L_1 of the external cavities.

25 7. A tread according to any one of Claims 1 to 6, characterized in that the internal and external cavities of one and the same said continuous groove do not overlap in the direction of the thickness E of the tread.

8. A tread according to any one of Claims 1 to 7, characterized in that at least two said external cavities are each extended by

a said connecting channel, said connecting channels opening onto one and the same said internal cavity.

5 9. A tread according to any one of Claims 1 to 8, characterized in that each said external cavity of at least one said continuous groove is extended at each of its ends by two said connecting channels, said connecting, said channels each opening into a separate said internal cavity.

10 10. A tread according to any one of Claims 1 to 9, characterized in that the tread includes additional cavities situated in a third said wearing layer which extends the second wearing layer radially on the inside, said additional cavities being connected to the internal cavities of the second wearing layer by additional said connecting channels.

15 11. A tread according to Claim 1, characterized in that the tread includes a first plurality of continuous grooves which are formed of a plurality of said external and internal cavities connected by said connecting channels, said continuous grooves being oriented in a first direction, and in that the tread includes a second plurality of continuous grooves which are formed of a
20 plurality of said external and internal cavities connected by said connecting channels, the grooves of the second plurality of continuous grooves being oriented in a second direction that intersects the first direction to form a network of criss-cross grooves, the internal cavities of the second plurality of
25 continuous grooves being connected to the internal cavities of the first plurality of continuous grooves.

12. A tread according to Claim 11, characterized in that depths of each said internal or external cavity is less than the total thickness E of the tread.

30 13. A tread according to Claim 11 or Claim 12, characterized in that a distance a between each said internal cavity and the tread

surface of the tread in the as-new condition is greater than 25% of the total thickness E of the tread.

14. A tread according to Claim 1, characterized in that it includes a plurality of grooves which are formed of a plurality of said external and internal cavities connected by connecting channels, said grooves being oriented in the longitudinal direction of the tread and being arranged in such a way that the first cavities that open onto the tread surface in the as-new condition are arranged offset from one another in the longitudinal direction, and in that the second cavities are also arranged offset from one another in the longitudinal direction.

15. A tread according to Claim 14, characterized in that depths of each said internal or external cavity is less than the total thickness E of the tread.

16. A tread according to Claim 14 or Claim 15, characterized in that a distance a between each said internal cavity and the tread surface of the tread in the as-new condition is greater than 25% of the total thickness E of the tread.

17. A tread according to any one of Claims 1 to 16, characterized in that the continuous grooves formed of at least external cavities and internal cavities connected by connecting channels have a wavy overall shape.

18. A tread according to any one of Claims 1 to 17, characterized in that each said external cavity that opens onto the tread in the as-new condition is extended radially towards the inside by an incision as far as the bottom of the tread, said incision also being connected to two connecting channels and to two internal cavities.

19. A tread according to any one of Claims 1 to 18, characterized in that the tread further includes at least one channel that is entirely situated within the tread and designed to form a new

groove by opening onto the tread surface after partial wear that is at most equal to the thickness of the first wearing layer.

5 20. A tread according to Claim 19, characterized in that the tread further includes means for placing at least one said channel in communication with a plurality of said internal cavities of a said continuous groove.

10 21. A tread according to any one of Claims 1 to 20, characterized in that the tread includes a plurality of channels opening onto edges of the tread, said channels opening into at least one said internal cavity of a said continuous groove.

15 22. A tyre provided with a tread according to any one of Claims 1 to 21, said tyre being characterized in that the mean length of the external cavities of the circumferential continuous grooves is between 25% and 75% of the mean length T of the contact patch of the tyre measured under nominal conditions of use of said tyre.
