UNITED STATES PATENT OFFICE

FREDERICK S. KINGSTON, OF WARREN, OHIO, ASSIGNOR TO THE SUNLIGHT ELECTRICAL
MANUFACTURING COMPANY, OF WARREN, OHIO, A CORPORATION OF OHIO

CLUTCH AND MOTOR CONSTRUCTION

Application filed June 11, 1927. Serial No. 198,093.

This invention relates to electric motors of the type and kind shown and described in my Patent No. 1,665,742 dated April 10, 1928, wherein electrically-controlled clutch means is provided to increase the starting torque and effect starting with a small amount of electric current, the primary purpose being to safeguard operation of the motor and to avoid objectionable drain and marked fluctuation of current in starting. The present device is an improvement involving a similar electrically-controlled clutch. The coil for the clutch is mounted within a channeled seat in one end cap for the motor, and the clutch is provided with a flat ring armature opposite this coil, and the movement of this armature toward the coil is under the control of two springs, one to effect a clutching action and the other to act as a cushioning buffer and stop to prevent vibration and noise when an alternating current, say 60 cycle A. C., is passing through the coil, all as hereinafter shown and described and more concisely set forth in the claims.

In the accompanying drawings, Fig. 1 is a sectional view longitudinally of a motor embodying my improvements. Fig. 2 is an end view of the ring armature and clutch member on line 2-2 of Fig. 1. Fig. 3 is an end view and cross section on line 3-3 of Fig. 1, showing the centrifugal switch members and triplex cup for controlling the starting winding. Fig. 4 is a perspective view of one of the switch members.

The motor, as shown, comprises a stator S having a main winding which may be divided to form two separate sets of coils 2 and 3, respectively, both of which may be used for running purposes, and one cut out for an interval in starting operations. A separate starting winding 4 is also used, and this winding is in circuit only for an interval or until a set of centrifugal switch elements 5 is thrown out of contact from a three part or triplex switch cup 6 stationed at one side of the rotor R carrying the switch elements 5. These elements are pivotally mounted upon a disk or ring 7 and are thrown inwardly by springs 8 to establish contact with cup 6, each element or pivoted arm 5 having a pair of loosely pivoted pieces 9-9 at their free ends, and each piece 9 having two contact extremities 10-10 adapted to span the gaps between the sections of the cup when in a bridging position in respect thereto and adapted to contact at four places on the cup sections, thereby assuring good conductivity for the current and absence of sparking.

Rotor R is free to revolve on motor shaft 11 and carries a dished clutch member 12 at one side thereof. A sliding cone or beveled clutch member 14 is keyed to shaft 11 and faced with leather or other friction material to coact with the dished member 12 in driving the shaft when the motor is running under load. A flat ring or plate 15 is affixed to or forms an integral part of clutch member 14, being preferably spaced apart from hub 16 and also the friction head thereon but connected therewith by radial ribs 17 which serve as fan blades when shaft 11 is in motion. A coiled spring 18 is sleeved loosely on shaft 11 between a fixed collar 19 and hub 16, thereby maintaining friction engagement between the respective clutch members at all times except in starting. In that interval spring 18 is compressed and cone member 14 is disengaged from member 12 by electro-magnetic pull on plate 15 which is spaced apart from a magnet coil 20 confined within an annular channel 21 formed by a pair of concentric ribs 22 extending inwardly from the end wall of hood 23 of the motor. The ribbed and channeled portion of hood 23 is of substantially the same area and diameter as the plate or ring armature 15, and a circular space 24 surrounds shaft 11 opposite a corresponding opening 25 between hub 16 and the inner edge of the ring-shaped plate or armature 15, thereby forming an annular air intake passage for the fan blades 17. Hood 23 contains air inlet openings 26 around the bearing 27 which communicate with space 24, and the other end hood 23' of the motor is also provided with openings 28 to promote circulation of the air through the motor.

I find that in using an alternating current to energize magnet coil 20 and draw the ring armature 15 of clutch member 14 counter to the pressure of spring 18, a certain amount of

vibration will result and cause an objectionable sound or noise. This is obviated by using a resilient buffer for clutch member 14, which in the present instance is in the form 5 of a heavy coiled spring 29 adapted to seat or bear against bearing 27 or the inner side of hood 23 and to be engaged by hub 16 or a separate plate 30 interposed between the hub and said spring. This buffer spring 29 is 10 preferably not compressed or under tension when inactive but is spaced apart from the hub or plate 30 at the beginning of the releasing movement of clutch member 14 thus permitting this clutch member to be freely actuated by the magnet. However as soon as the 15 clutch members are separated the buffer spring is engaged and supplements the pressure of spring 18 to prevent the ring armature or plate 15 from rubbing against magnet coil 20 and ribs 22, and the vibration is 20 counter-acted and reduced to a minimum and objectionable sounds prevented.

What I claim is:

1. In an electric motor including a perforated hood, a drive shaft and a rotor freely rotatable on said drive shaft, an electro-magnetic clutch, comprising an electro-magnetic coil mounted on said hood, a shiftable spring-pressed clutch member connected with the 25 shaft, a complementary clutch member connected to the rotor and a ring-shaped armature cooperating with said electro-magnetic coil, and connected to said shiftable clutch member by means of radial ribs extending 30 from the clutching part of said clutch member.
2. In an electric motor including a perforated hood, a drive shaft and a rotor freely rotatable on said drive shaft, an electro-magnetic clutch comprising an electro-magnetic coil mounted in a channeled portion of said 35 hood encircling the perforated part thereof centrally with respect to said shaft, a clutch member fixed to said rotor, a shiftable clutch member mounted on said shaft having a clutching part and a ring-shaped armature connected therewith, and spring means for holding said clutch members normally engaged.
3. In an electric motor including a perforated hood, a drive shaft and a rotor freely rotatable on said drive shaft, an electro-magnetic clutch, comprising an electro-magnetic coil supported within a cylindrical channel 50 formed by parallel walls integrally extending from the inner side of the hood and centrally with respect to the drive shaft, a clutch member mounted on said rotor, a shiftable clutch member having a clutching part and a ring-shaped armature connected therewith by radial ribs, spring means for normal engagement of said clutch, and buffer means for said shiftable clutch member coacting 55 with said spring means to counteract a shift-

ing movement of said clutch member by said electro-magnetic coil.

4. In an electric motor including a perforated hood, a drive shaft and a rotor freely rotatable on said drive shaft, an electro-magnetic clutch according to claim 3, in which said buffer means consists of a heavy spring 70 slightly spaced apart from said shiftable clutching member.

5. In an electric motor including a perforated hood, a drive shaft and a rotor freely rotatable on said drive shaft, an electro-magnetic clutch, comprising an electro-magnetic coil mounted in a channeled portion of said hood extending inwardly from the wall thereof centrally with respect to said shaft, a clutch member fixed to said rotor, a shiftable clutch member associated with said rotor, clutch member having a clutching part and a ring-shaped armature connected therewith by ribs of substantial surface area, and spring means for holding said clutch members normally engaged.

6. In an electric motor including a perforated hood, a drive shaft and a rotor freely rotatable on said drive shaft, an electro-magnetic clutch comprising an electro-magnetic coil mounted in a channeled portion of said hood centrally with respect to said shaft, a clutch member fixed to said rotor, a shiftable clutch member associated with said rotor clutch member having a clutching part and a ring-shaped armature connected therewith by ribs of substantial surface area, and spring means for normal engagement of said clutch.

In testimony whereof I affix my signature.
FREDERICK S. KINGSTON.
