IMIDAZO[4,5-c]CINNOLIN-2-ONE AS SELECTIVE MODULATORS OF ATAXIA  
TELANGIECTASIA MUTATED (ATM) KINASE AND USES THEREOF**

**FIELD OF THE DISCLOSURE**

The present application relates to novel substituted imidazo[4,5-c]cinnolin-2-one compounds and pharmaceutically acceptable salts thereof, which selectively modulate ataxia telangiectasia mutated (“ATM”) kinase. The present application also relates to pharmaceutical compositions comprising one or more of the compounds and salts thereof as an active ingredient, and to the use of the compounds and salts thereof in the treatment of ATM-associated diseases or conditions, including cancers.

**BACKGROUND OF THE DISCLOSURE**

ATM kinase, a serine/threonine kinase, is named after the autosomal recessive disorder ataxia-telangiectasia (A-T) (Paul, T. T, *Annu Rev Biochem* **2015**, 711-38). ATM plays a central role in the repair of DNA double-strand breaks (DSB), which is very cytotoxic if not timely repaired. DSBs can be repaired by two major pathways: Non-Homologous End Joining (NHEJ) or Homologous Recombination (HR). NHEJ operates throughout the cell cycle, directly resealing the two broken ends with minimal processing. In contrast, HR takes place during the S and G2 phases of the cell cycle and necessitates extensive end processing (or resection). This generates single-stranded DNA that invades the homologous copy of the broken locus which is then used as a template for DNA synthesis (Clouaire, T. et al, *DNA Repair (Amst)* **2017**, 84-91). In comparison, NHEJ is a fast process but error prone; whereas HR is a slower process than NHEJ, but error free. ATM fixes DSBs through HR.

Following DNA DSBs, ATM is recruited by the MRE11-RAD50-NBS1 (MRN) complex which senses and initiates DNA repair. As ATM is brought to the site of DNA damage, it dissociates from inactive homodimers into active monomers and is catalytically activated by autophosphorylation at Ser1981 and other sites, as well as acetylation at Lys3016. ATM then binds to the C terminus of NBS1, a component of the MRN complex, and serves as a

transducer and phosphorylates and activates other protein kinases, for example the histone H2A.X ( $\gamma$ H2A.X).

ATM is activated by DSBs which can be induced by ionizing radiation, chemotherapy drugs and PARP inhibition. Topoisomerase-I inhibitor (such as irinotecan, topotecan) and PARP inhibitor (such as Olaparib) cause single strand DNA breaks which are converted to DSBs during replication (Choi M. et al, *Mol Cancer Ther*, **2016**, 1781-91). Other anti-cancer treatments such as ionizing radiation (IR), Platinum drugs (Cisplatin), topoisomerase-II inhibitors (doxorubicin, etoposide) directly induces DSBs. Combination of ATM inhibitor with chemotherapy, radiation and PARP inhibitors make cancer cells nearly impossible to repair DSBs which are very cytotoxic. Given the crucial role of ATM played during DSBs, ATM kinase inhibitors are expected to synergize with PARP or Topoisomerase inhibitors or ionizing radiation in the treatment of cancer.

A number of structurally distinct compounds have been reported by showing activity against ATM kinase. WO2015/170081, WO2017/046216 and WO2017/076895 (Astrazeneca AB) reported imidazo[4,5-c]quinolin-2-one compounds as selective modulators of ATM kinase, among which AZD0156 and AZD1390 are potent ATM inhibitors in phase 1 clinical trial:

AZD0156

AZD1390

However, both compounds are aldehyde oxidase (AO) substrates with high activity. AO is highly expressed in humans and monkeys, not in dogs and has low expression level in rodents. Compounds metabolized by AO showed high clearance, high PK variability and low oral bioavailability in humans (Garattini, E. et al., *Expert Opin Drug Discovery*, **2013**, 641-54; Zientek, M. et al., *Drug Metab Dispos* **2010**, 1322-7). AO liability can be evaluated in human liver cytosol system. AZD0156's human PK is unexpectedly lower than prediction (Chen et al., *AACR*, **2018**) and a phase 0 clinical PK study was conducted for AZD1390 before making commitment to phase 1 clinical study (NCT03215381 and

NCT03423628), further alluding that both AZD0156 and AZD1390 suffer from AO mediated metabolism. Furthermore, AZD0156 is not capable of brain penetration limiting its use for treating tumors in the brain. AZD1390 shows hERG liability, which have cardiac adverse effects.

Accordingly, there remains a need to develop new compounds that act against ATM kinase, preferably being brain penetrable without AO and hEGR liability.

### **SUMMARY OF THE DISCLOSURE**

Disclosed herein are novel substituted imidazo[4,5-c]cinnolin-2-one compounds that possess potent ATM kinase inhibitory activity, do not show AO liability in human liver cytosol and thus have good human pharmacokinetics (PK), low dose and low PK variability. In addition, these compounds are neither human Pgp nor human BCRP substrates, demonstrate good brain penetration in animals, and possess favourable toxicity profiles (for example a decreased activity against hERG). As a result, the compounds of the present application are particularly useful in the treatment of ATM-associated diseases or conditions, including cancers (not only extracranial cancers, but also tumors in brains).

As used herein, the term “partially unsaturated” refers to a radical that includes at least one double or triple bond. The term “partially unsaturated” is intended to encompass rings having multiple sites of unsaturation, but is not intended to include aromatic (i.e., fully unsaturated) moieties.

As used herein, the term “substituted”, whether preceded by the term "optionally" or not, means that one or more hydrogens of the designated moiety are replaced with a suitable substituent. It will be understood that “substitution” or “substituted with” includes the implicit proviso that such substitution is in accordance with permitted valence of the substituted atom and that the substitution results in a stable or chemically feasible compound, e.g., which does not spontaneously undergo transformation such as by rearrangement, cyclization, elimination, etc. Unless otherwise indicated, an “optionally substituted” group may have a suitable substituent at each substitutable position of the group, and when more than one position in any given structure may be substituted with more than one substituent selected from a specified group, the substituent may be either the same or different at every position. It will be understood by those skilled in the art that substituents can themselves be substituted, if appropriate. Unless specifically stated as “unsubstituted”, references to chemical moieties herein are understood to include substituted variants. For example,

reference to an “aryl” group or moiety implicitly includes both substituted and unsubstituted variants.

When a bond to a substituent is shown to cross a bond connecting two atoms in a ring, then such substituent may be bonded to any atom in the ring. When a substituent is listed without indicating the atom via which such substituent is bonded to the rest of the compound of a given formula, then such substituent may be bonded via any atom in such formula. Combinations of substituents and/or variables are permissible, but only if such combinations result in stable compounds.

When any variable (e.g.,  $R^1$ ) occurs more than one time in any constituent or formula for a compound, its definition at each occurrence is independent of its definition at every other occurrence. Thus, for example, if a group is shown to be substituted with 0-2  $R^1$  moieties, then the group may optionally be substituted with up to two  $R^1$  moieties and  $R^1$  at each occurrence is selected independently from the definition of  $R^1$ . Also, combinations of substituents and/or variables are permissible, but only if such combinations result in stable compounds.

Compounds provided herein are described with reference to both generic formulae and specific compounds. In addition, compounds of the present disclosure may exist in a number of different forms or derivatives, all within the scope of the present disclosure. These include, for example, tautomers, stereoisomers, racemic mixtures, regioisomers, salts, prodrugs, solvated forms, different crystal forms or polymorphs, and active metabolites.

The compounds of present disclosure can comprise one or more asymmetric centers, and thus can exist in various stereoisomeric forms, e.g., enantiomers and/or diastereomers.

Thus, inventive compounds and compositions thereof may be in the form of an individual enantiomer, diastereomer or geometric isomer, or may be in the form of a mixture of stereoisomers. In certain embodiments, the compounds of the present disclosure are enantiopure compounds. In certain embodiments, mixtures of enantiomers or diastereomers are provided.

The term “enantiomer” refers to two stereoisomers of a compound which are non-superimposable mirror images of one another. The term “diastereomer” refers to a pair of optical isomers which are not mirror images of one another. Diastereomers have different physical properties, e.g. melting points, boiling points, spectral properties, and reactivities.

Furthermore, certain compounds, as described herein may have one or more double bonds that can exist as either the Z or E isomer, unless otherwise indicated. The present disclosure additionally encompasses the compounds as individual isomers substantially free of other isomers and alternatively, as mixtures of various isomers, e.g., racemic mixtures of enantiomers. In addition to the above-mentioned compounds per se, this disclosure also encompasses compositions comprising one or more compounds.

As used herein, the term “isomers” includes any and all geometric isomers and stereoisomers. For example, “isomers” include cis- and trans-isomers, E- and Z- isomers, R- and S-enantiomers, diastereomers, (D)-isomers, (L)-isomers, racemic mixtures thereof, and other mixtures thereof, as falling within the scope of the invention. For instance, a stereoisomer may, in some embodiments, be provided substantially free of one or more corresponding stereoisomers, and may also be referred to as “stereochemically enriched”.

Where a particular enantiomer is preferred, it may, in some embodiments be provided substantially free of the opposite enantiomer, and may also be referred to as “optically enriched”. “Optically enriched”, as used herein, means that the compound is made up of a significantly greater proportion of one enantiomer. In certain embodiments, the compound is made up of at least about 90% by weight of a preferred enantiomer. In other embodiments, the compound is made up of at least about 95%, 98%, or 99% by weight of a preferred enantiomer. Preferred enantiomers may be isolated from racemic mixtures by any method known to those skilled in the art, including chiral high pressure liquid chromatography (HPLC) and the formation and crystallization of chiral salts or prepared by

asymmetric syntheses. See, for example, Jacques, et al., *Enantiomers, Racemates and Resolutions* (Wiley Interscience, New York, 1981); Wilen, S.H., et al., *Tetrahedron* 33:2725 (1977); Eliel, E.L. *Stereochemistry of Carbon Compounds* (McGraw-Hill, NY, 1962); Wilen, S.H. *Tables of Resolving Agents and Optical Resolutions* p. 268 (E.L. Eliel, Ed., Univ. of Notre Dame Press, Notre Dame, IN 1972).

The compounds of the present disclosure may also exist in different tautomeric forms, and all such forms are embraced within the scope of the present disclosure. The term “tautomer” or “tautomeric form” refers to structural isomers of different energies which are interconvertible via a low energy barrier. For example, proton tautomers (also known as prototropic tautomers) include interconversions via migration of a proton, such as keto-enol, amide-imidic acid, lactam-lactim, imine-enamine isomerizations and annular forms where a proton can occupy two or more positions of a heterocyclic system (for example, 1H- and 3H-imidazole, 1H-, 2H- and 4H- 1,2,4-triazole, 1H- and 2H- isoindole, and 1H- and 2H-pyrazole). Valence tautomers include interconversions by reorganization of some of the bonding electrons. Tautomers can be in equilibrium or sterically locked into one form by appropriate substitution. Compounds of the present disclosure identified by name or structure as one particular tautomeric form are intended to include other tautomeric forms unless otherwise specified.

The compounds of the present disclosure also include prodrugs, active metabolic derivatives (active metabolites), active intermediates, and their pharmaceutically acceptable salts.

As used herein, the term “prodrugs” refers to compounds or pharmaceutically acceptable salts thereof which, when metabolized under physiological conditions or when converted by solvolysis, yield the desired active compound. Prodrugs include, without limitation, esters, amides, carbamates, carbonates, ureides, solvates, or hydrates of the active compound. Typically, the prodrug is inactive, or less active than the active compound, but may provide one or more advantageous handling, administration, and/or metabolic properties. For example, some prodrugs are esters of the active compound; during metabolism, the ester group is cleaved to yield the active drug. Also, some prodrugs are activated enzymatically to yield the active compound, or a compound which, upon further

chemical reaction, yields the active compound. Prodrugs may proceed from prodrug form to active form in a single step or may have one or more intermediate forms which may themselves have activity or may be inactive. Preparation and use of prodrugs is discussed in T. Higuchi and V. Stella, "Pro-drugs as Novel Delivery Systems", Vol. 14 of the A.C.S. Symposium Series, and in *Bioreversible Carriers in Drug Design*, ed. Edward B. Roche, American Pharmaceutical Association and Pergamon Press, 1987, both of which are hereby incorporated by reference in their entirety.

As used herein, the term "metabolite", e.g., active metabolite overlaps with prodrug as described above. Thus, such metabolites are pharmacologically active compounds or compounds that further metabolize to pharmacologically active compounds that are derivatives resulting from metabolic process in the body of a subject. For example, such metabolites may result from oxidation, reduction, hydrolysis, amidation, deamidation, esterification, deesterification, enzymatic cleavage, and the like, of the administered compound or salt or prodrug. Of these, active metabolites are such pharmacologically active derivative compounds. For prodrugs, the prodrug compound is generally inactive or of lower activity than the metabolic product. For active metabolites, the parent compound may be either an active compound or may be an inactive prodrug.

Prodrugs and active metabolites may be identified using routine techniques known in the art. See, e.g., Bertolini et al, 1997, *J Med Chem* 40:2011-2016; Shan et al., *J Pharm Sci* 86:756-757; Bagshawe, 1995, *DrugDev Res* 34:220-230; Wermuth, *supra*.

As used herein, the term "active intermediate" refers to intermediate compound in the synthetic process, which exhibits the same or essentially the same biological activity as the final synthesized compound.

Compounds of the present disclosure can be formulated as or be in the form of pharmaceutically acceptable salts. Unless specified to the contrary, a compound provided herein includes pharmaceutically acceptable salts of such compound.

As used herein, the term "pharmaceutically acceptable" indicates that the substance or composition is compatible chemically and/or toxicologically, with the other ingredients comprising a formulation, and/or the subjects being treated therewith.

As used herein, the term "pharmaceutically acceptable salt", unless otherwise indicated,

includes salts that retain the biological effectiveness of the free acids and bases of the specified compound and that are not biologically or otherwise undesirable. Contemplated pharmaceutically acceptable salt forms include, but are not limited to, mono, bis, tris, tetrakis, and so on. Pharmaceutically acceptable salts are non-toxic in the amounts and concentrations at which they are administered. The preparation of such salts can facilitate the pharmacological use by altering the physical characteristics of a compound without preventing it from exerting its physiological effect. Useful alterations in physical properties include lowering the melting point to facilitate transmucosal administration and increasing the solubility to facilitate administering higher concentrations of the drug.

Pharmaceutically acceptable salts include acid addition salts such as those containing sulfate, chloride, hydrochloride, fumarate, maleate, phosphate, sulfamate, acetate, citrate, lactate, tartrate, methanesulfonate, ethanesulfonate, benzenesulfonate, p-toluenesulfonate, cyclohexylsulfamate and quinate. Pharmaceutically acceptable salts can be obtained from acids such as hydrochloric acid, maleic acid, sulfuric acid, phosphoric acid, sulfamic acid, acetic acid, citric acid, lactic acid, tartaric acid, malonic acid, methanesulfonic acid, ethanesulfonic acid, benzenesulfonic acid, p-toluenesulfonic acid, cyclohexylsulfamic acid, fumaric acid, and quinic acid.

Pharmaceutically acceptable salts also include basic addition salts such as those containing benzathine, chlorprocaine, choline, diethanolamine, ethanolamine, t-butylamine, ethylenediamine, meglumine, procaine, aluminum, calcium, lithium, magnesium, potassium, sodium, ammonium, alkylamine, and zinc, when acidic functional groups, such as carboxylic acid or phenol are present. For example, see Remington's Pharmaceutical Sciences, 19<sup>th</sup>ed., Mack Publishing Co., Easton, PA, Vol. 2, p. 1457, 1995; "Handbook of Pharmaceutical Salts: Properties, Selection, and Use" by Stahl and Wermuth, Wiley-VCH, Weinheim, Germany, 2002. Such salts can be prepared using the appropriate corresponding bases.

Pharmaceutically acceptable salts can be prepared by standard techniques. For example, the free-base form of a compound can be dissolved in a suitable solvent, such as an aqueous or aqueous-alcohol solution containing the appropriate acid and then isolated by evaporating the solution. Thus, if the particular compound is a base, the desired pharmaceutically acceptable salt may be prepared by any suitable method available in the art,

for example, treatment of the free base with an inorganic acid, such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid and the like, or with an organic acid, such as acetic acid, maleic acid, succinic acid, mandelic acid, fumaric acid, malonic acid, pyruvic acid, oxalic acid, glycolic acid, salicylic acid, a pyranosidyl acid, such as glucuronic acid or galacturonic acid, an alpha-hydroxy acid, such as citric acid or tartaric acid, an amino acid, such as aspartic acid or glutamic acid, an aromatic acid, such as benzoic acid or cinnamic acid, a sulfonic acid, such as p-toluenesulfonic acid or ethanesulfonic acid, or the like.

Similarly, if the particular compound is an acid, the desired pharmaceutically acceptable salt may be prepared by any suitable method, for example, treatment of the free acid with an inorganic or organic base, such as an amine (primary, secondary or tertiary), an alkali metal hydroxide or alkaline earth metal hydroxide, or the like. Illustrative examples of suitable salts include organic salts derived from amino acids, such as L-glycine, L-lysine, and L-arginine, ammonia, primary, secondary, and tertiary amines, and cyclic amines, such as hydroxyethylpyrrolidine, piperidine, morpholine or piperazine, and inorganic salts derived from sodium, calcium, potassium, magnesium, manganese, iron, copper, zinc, aluminum and lithium.

It is also to be understood that the compounds of present disclosure can exist in unsolvated forms, solvated forms (e.g., hydrated forms), and solid forms (e.g., crystal or polymorphic forms), and the present disclosure is intended to encompass all such forms.

As used herein, the term “solvate” or “solvated form” refers to solvent addition forms that contain either stoichiometric or non stoichiometric amounts of solvent. Some compounds have a tendency to trap a fixed molar ratio of solvent molecules in the crystalline solid state, thus forming a solvate. If the solvent is water the solvate formed is a hydrate; and if the solvent is alcohol, the solvate formed is an alcoholate. Hydrates are formed by the combination of one or more molecules of water with one molecule of the substance in which the water retains its molecular state as H<sub>2</sub>O.

As used herein, the terms “crystal form”, “crystalline form”, “polymorphic forms” and “polymorphs” can be used interchangeably, and mean crystal structures in which a compound (or a salt or solvate thereof) can crystallize in different crystal packing arrangements, all of

which have the same elemental composition. Different crystal forms usually have different X-ray diffraction patterns, infrared spectral, melting points, density hardness, crystal shape, optical and electrical properties, stability and solubility. Recrystallization solvent, rate of crystallization, storage temperature, and other factors may cause one crystal form to dominate. Crystal polymorphs of the compounds can be prepared by crystallization under different conditions.

The present disclosure is also intended to include includeall isotopes of atoms in the compounds. Isotopes of an atom include atoms having the same atomic number but different mass numbers. For example, unless otherwise specified, hydrogen, carbon, nitrogen, oxygen, phosphorous, sulphur, fluorine, chlorine, bromide or iodine in the compounds of present disclosure are meant to also include their isotopes, such as but not limited to  $^1\text{H}$ ,  $^2\text{H}$ ,  $^3\text{H}$ ,  $^{11}\text{C}$ ,  $^{12}\text{C}$ ,  $^{13}\text{C}$ ,  $^{14}\text{C}$ ,  $^{14}\text{N}$ ,  $^{15}\text{N}$ ,  $^{16}\text{O}$ ,  $^{17}\text{O}$ ,  $^{18}\text{O}$ ,  $^{31}\text{P}$ ,  $^{32}\text{P}$ ,  $^{32}\text{S}$ ,  $^{33}\text{S}$ ,  $^{34}\text{S}$ ,  $^{36}\text{S}$ ,  $^{17}\text{F}$ ,  $^{19}\text{F}$ ,  $^{35}\text{Cl}$ ,  $^{37}\text{Cl}$ ,  $^{79}\text{Br}$ ,  $^{81}\text{Br}$ ,  $^{127}\text{I}$  and  $^{131}\text{I}$ . In some embodiments, hydrogen includes protium, deuterium and tritium. In some embodiments, carbon includes  $^{12}\text{C}$  and  $^{13}\text{C}$ .

### USE OF COMPOUNDS

In an aspect, the present disclosure provides compounds of formula (I) or pharmaceutically acceptable salts thereof, which show ATM kinase inhibitory activity.

As used herein, the term “ATM kinase inhibitory activity” refers to a decrease in the activity of ATM kinase as a direct or indirect response to the presence of a compound of Formula (I), or pharmaceutically acceptable salt thereof, relative to the activity of ATM kinase in the absence of compound of Formula (I), or pharmaceutically acceptable salt thereof. Such a decrease in activity may be due to the direct interaction of the compound of Formula (I), or pharmaceutically acceptable salt thereof with ATM kinase, or due to the interaction of the compound of Formula (I), or pharmaceutically acceptable salt thereof with one or more other factors that in turn affect ATM kinase activity. For example, the compound of Formula (I), or pharmaceutically acceptable salt thereof may decrease ATM

kinase by directly binding to the ATM kinase, by causing (directly or indirectly) another factor to decrease ATM kinase activity, or by (directly or indirectly) decreasing the amount of ATM kinase present in the cell or organism.

In some embodiments, the compounds of the present disclosure are selective inhibitors of ATM kinase.

As used herein, the term “selective inhibitor” or “selectively inhibits” means that a provided compound inhibits ATM kinase in at least one assay described herein (e.g., biochemical or cellular). In some embodiments, the term “selective inhibitor” or “selectively inhibits” means that a provided compound has the  $IC_{50}$  for inhibiting the enzymes in PIKK family closely related to ATM kinase (such as PI3K, mTOR and ATR) at least 5000 fold higher, at least 4000 fold higher, at least 3000 fold higher, at least 2000 fold higher, at least 1000 fold higher, at least 500 fold higher, at least 400 fold higher, at least 300 fold higher, at least 200 fold higher, at least 100 fold higher, at least 90 fold higher, at least 80 fold higher, at least 70 fold higher, at least 60 fold higher, at least 50 fold higher, at least 40 fold higher, at least 30 fold higher, at least 20 fold higher, at least 10 fold higher, than the  $IC_{50}$  for inhibiting ATM kinase.

In some embodiments, the compounds of the present disclosure are not AO substrates, as determined in human liver cytosol.

As used herein, the term “AO substrate” means that a given compound is susceptible to oxidation by aldehyde oxidase (“AO”) and thus highly susceptible to AO mediated clearance. In some embodiments, the AO susceptibility of a compound can be evaluated by intrinsic clearance ( $CL_{int}$ ) in human liver cytosol system (Zientek M. et al, *Drug Metab Dispos*, **2010**, 1322-27), as described in detail in Example section below. Human liver cytosol system useful in the evaluation is commercially available, for example, from Xenotech with catalog number H0606.C (AX) and lot number 1710130. In general, human liver cytosolic extracts can be prepared by ultra-centrifugation of liver homogenates obtained from human donors. In certain embodiments, the human liver cytosolic extracts (e.g. H0606.C (AX) from Xenotech) can be made specifically from donors with high AO activity to minimize underprediction of AO mediated clearance. In some embodiments, PF-04217903 (2-[4-[3-(quinolin-6-ylmethyl)triazolo[4,5-b]pyrazin-5-yl]pyrazol-1-yl]ethanol, reported as a weak

AO substrate) and Zaleplon (N-[3-(3-cyanopyrazolo[1,5-a]pyrimidin-7-yl)phenyl]-N-ethylacetamide, considered as a strong AO substrate) are both used as references in human liver cytosolic system. In certain embodiments, a compound will not be considered as an AO substrate if the compound shows an  $CL_{int}$  lower than that of PF-04217903 (1.8  $\mu\text{L}/\text{min}/\text{mg}$  protein), while a compound will be considered as a strong AO substrate if the compound shows an  $CL_{int}$  higher than that of Zaleplon (3.1  $\mu\text{L}/\text{min}/\text{mg}$  protein), wherein the  $CL_{int}$  is determined by the AO assay described in the AO assay described in Example section below.

In some embodiments, the compounds of the present disclosure show low AO susceptibility with a  $CL_{int}$  in human hepatocyte of less than about 1.8  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.7  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.6  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.5  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.4  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.3  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.2  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1.1  $\mu\text{L}/\text{min}/\text{mg}$  protein, 1  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.9  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.8  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.7  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.6  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.5  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.4  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.3  $\mu\text{L}/\text{min}/\text{mg}$  protein, 0.2  $\mu\text{L}/\text{min}/\text{mg}$  protein, or 0.1  $\mu\text{L}/\text{min}/\text{mg}$  protein.

AOs are cytosolic molybdo-flavoenzymes, a group of proteins that require a flavin adenine dinucleotide (FAD) and a molybdopterin [molybdenum cofactor (MoCo)] for their catalytic activity. AOs oxidize aromatic aldehydes into the corresponding carboxylic acids and heterocycles into hydroxylated derivatives. The potential of AO to oxidize heterocycles is of particular importance in the context of drug design and development, as these chemical groups are popular synthetic blocks in medicinal chemistry. AO mediated metabolism is often overlooked during drug discovery stage, and high clearance issue is not revealed until in phase 1 clinical trial. AO is a cytosolic enzyme and thus its potential contribution to the metabolic clearance of new compounds is not addressed in standard metabolic stability screens using liver microsomes. Hepatocytes are a whole cell system which contains both microsomes and cytosol. However, AO is an unstable protein with substantial loss in activity during hepatocytes preparation (Hutzler, J. M. et al., *Drug Metab Dispos*, **2014**, 1090-7). In vivo studies on AO mediated metabolism in animal models are also highly problematic, as the components liver AOs in humans and in popular experimental animals are different (Garattini, E. et al., *Expert Opin Drug Discovery*, **2013**, 641-54). Human liver

is characterized by a single and active AO isozyme, that is, AOX1. The predominant AOX form expressed in many mouse and rat strains is AOX3. Two other experimental animals, cats and dogs, are characterized by absence of AO enzymatic activity. AO activity has been found to be much more active in higher primates (humans and monkeys) compared to rodents. AO is very concentrated in the liver, where it oxidizes multiple aldehydes and nitrogenous heterocyclic compounds, such as anti-cancer and immunosuppressive drugs (see, for example, Gordon AH, Green DE, Subrahmanyam, "Liver aldehyde oxidase", *The Biochemical Journal*. 1940, **34**(5): 764-74). Human liver cytosolic extracts, which contain AO, but not significant amount of contaminating CYP450, has been shown to be a valuable tool to predict in vivo clearance mediated by human AO. Human liver cytosol purchased from Xenotech was used immediately after thawing, and not reused as AO is an unstable enzyme and becomes rapidly inactivated upon freezing-thawing. In light of highly variable AO activity, a high activity lot of human liver cytosol, was chosen for AO assay to minimize underprediction of clearance. Reference compounds Zaleplon (high clearance by AO) and PF-04217903 (low clearance by AO) were used as controls in the AO assay.

Without wishing to be bound by any particular theory, it is believed that AO has a significant impact on pharmacokinetics. AO is capable of oxidizing many drugs in the liver, because of its broad substrate specificity (Strelevitz TJ, Orozco CC, Obach RS. "Hydralazine as a selective probe inactivator of aldehyde oxidase in human hepatocytes: estimation of the contribution of aldehyde oxidase to metabolic clearance". *Drug Metabolism and Disposition*. 2012, **40** (7): 1441-8). AO greatly contributes to the hepatic clearance of drugs and other compounds (Hartmann T, Terao M, Garattini E, Teutloff C, Alfaro JF, Jones JP, Leimkühler S. "The impact of single nucleotide polymorphisms on human aldehyde oxidase", *Drug Metabolism and Disposition*. 2012, **40** (5): 856-64). AO mediated metabolism tends to lead to high clearance in humans. For high clearance compounds, small change in intrinsic clearance due to different enzyme expression level among patients causes large change of bioavailability. The human AOX1 is highly polymorphic and some inactivating missense as well as nonsense polymorphic sites have been described in the human population (Garattini, E. et al, *Expert Opin Drug Discovery*, 2012, 487-503; Hartmann, T. et al, *Drug Metab Dispos*, 2012, 856-64). Such polymorphism results in

reduced levels of the encoded AOX1 protein and explains the reported interindividual variability in AOX activity. Additionally many factors may affect AO activity, such as gender, age, cigarette smoking, drug usage, and disease states. Therefore, compounds with AO mediated high clearance have large inter-patients PK variability which results in unexpected toxicities in some individuals whereas efficacy is not achieved in other patients (Garattini, E. et al, *Expert Opin Drug Discovery*, **2013**, 641-54; Hutzler, J. M. et al, *Drug Metab Dispos* 2014, 1090-7).

In contrast to the previously reported ATM inhibitors AZD0156 and AZD1390 that are strong AO substrate, the compounds of the present disclosure have surprisingly low susceptibility to AO oxidation. Therefore, in one aspect, the compounds and pharmaceutically acceptable salts thereof provided herein are not AO substrates, and consequently show better PK profile than compounds that are AO substrates. For example, the compounds provided herein have low PK variability, among humans that have different levels of AO activity.

In some embodiments, the compounds of the present disclosure are not P-glycoprotein (Pgp) substrates, nor ATP-binding cassette sub-family G member 2 (ABCG2, or BCRP) substrates. As used herein, the term "Pgp substrate" means that a given compound is susceptible to transporation back into the intestinal lumen (in the case of Pgp distributed in intestinal epithelium), bile ducts (in the case of Pgp distributed in liver cells), urinar filtrate (in the case of Pgp distributed in the cells of the proximal tubule of the kidney), capillaries (in the case of Pgp distributed in the capillary endothelial cells composing the blood-brain barrier and blood-testis barrier) and the like, by Pgp. As used herein, the term "BCRP substrate" means that a given compound is blocked from being absorption at the apical membrane of the intestine, the blood-testis barrier, the blood-brain barrier, and the membranes of hematopoietic progenitor and other stem cells, in particular the blood-brain barrier, by BCRP. Therefore, there is provided compounds or pharmaceutically acceptable salts thereof, which demonstrate good brain penetration in subjects, allowing for applications in treating both extracranial cancers and metastatic cancer, such as brain metastases.

In some embodiments, the Pgp and BCRP susceptibility of a compound can be evaluated by MDCK-MDR1 Pgp permeability assay and Caco-2 BCRP permeability assay,

respectively, as described in detail in Example section below. In some embodiments, the compounds of the present disclosure show no Pgpsusceptibility with a MDCK-Pgp efflux ratio (MDCK-Pgp ER) of less than about 2.5.

In some embodiments, the compounds of the present disclosure are capable of crossing blood-brain barrier (BBB) without the need of an agent to facilitate BBB entry.

In some embodiments, the compounds of the present disclosure show low hERG inhibition, as determined by hERG inhibition assay described in detail in Example section below. In some embodiments, the compounds of the present disclosure show a hERG inhibition at 10  $\mu\text{M}$  is less than 70%, less than 65%, less than 60%, less than 55%, less than 50%, less than 45%, less than 40%, less than 35%, less than 30%, less than 25%, less than 20%.

In some embodiments, the compounds of the present disclosure show good solubility in water. In some embodiments, the compounds of the present disclosure show a solubility in water of above 90  $\mu\text{M}$ , above 100  $\mu\text{M}$ , above 200  $\mu\text{M}$ , above 300  $\mu\text{M}$ , above 400  $\mu\text{M}$ , above 500  $\mu\text{M}$ , above 600  $\mu\text{M}$ , above 700  $\mu\text{M}$ , above 800  $\mu\text{M}$ , above 900  $\mu\text{M}$ , or above 1000  $\mu\text{M}$ .

In some embodiments, the pharmaceutical composition comprises one or more compounds of the present disclosure, or a pharmaceutically acceptable salt thereof, and at least one pharmaceutical acceptable excipient.

A “pharmaceutical composition”, as used herein, is a formulation containing the compounds of the present disclosure in a form suitable for administration to a subject. In some embodiments, the pharmaceutical composition is in bulk or in unit dosage form. The unit dosage form is any of a variety of forms, including, for example, tablets, capsules, pills, powders, granules, sachets, cachets, lozenges, suspensions, emulsions, solutions, syrups, aerosols (as a solid or in a liquid medium), spray, ointment, paste, cream, lotion, gel, patch, inhalant, or suppository. One skilled in the art will appreciate that it is sometimes necessary to make routine variations to the dosage depending on the age and condition of the patient. The dosage will also depend on the route of administration. A variety of routes are contemplated, including oral, pulmonary, rectal, parenteral, transdermal, subcutaneous, intravenous, intramuscular, intraperitoneal, inhalational, buccal, sublingual, intrapleural, intrathecal, intranasal, and the like. #### METHOD FOR TREATMENT

In a further aspect, there is provided a method of treating ATM-associated diseases or conditions in a subject in need thereof, which comprises administering to the subject a therapeutically effective amount of a compound of Formula (I) or a pharmaceutically acceptable salt thereof, or a pharmaceutical composition of the present disclosure, owing to the selective ATM kinase inhibitory activity, non-AO, non-Pgp and non-BCRP liability and brain penetration capability of the compounds of the present disclosure.

In some embodiments, the ATM-associated disease or condition is cancer. In some embodiments, the cancer is selected from the group consisting of colorectal cancer, glioblastoma, gastric cancer, ovarian cancer, diffuse large B-cell lymphoma, chronic lymphocytic leukaemia, acute myeloid leukaemia, head and neck squamous cell carcinoma, breast cancer, hepatocellular carcinoma, small cell lung cancer and non-small cell lung cancer. In some embodiments, the cancer is metastatic cancer. In some embodiments, the metastatic cancer comprises metastases of the central nervous system. In some embodiments, the metastases of the central nervous system comprise brain metastases. In some embodiments, the metastases of the central nervous system comprise leptomeningeal metastases. "Leptomeningeal metastases" occur when cancer spreads to the meninges, the layers of tissue that cover the brain and the spinal cord. Metastases can spread to the meninges through the blood or they can travel from brain metastases, carried by the cerebrospinal fluid (CSF) that flows through the meninges.

In a further aspect, there is provided a method of treating Huntington's disease in a subject in need thereof, which comprises administering to the subject a therapeutically effective amount of a compound of Formula (I) or a pharmaceutically acceptable salt thereof, or a pharmaceutical composition of the present disclosure.

As used herein, the term "subject in need thereof" is a subject having an ATM-associated disease or condition (e.g., cancer), or a subject having an increased risk of

developing an ATM-associated disease or condition (e.g., cancer) relative to the population at large. In the case of cancer, a subject in need thereof can have a precancerous condition. A “subject” includes a warm-blooded animal. In some embodiments, the warm-blooded animal is a human.

In this context, the term “therapeutically effective amount” refers to an amount of a compound of Formula (I) or pharmaceutically acceptable salts thereof which is effective to provide “therapy” in a subject, or to “treat” an ATM-associated disease or disorder in a subject. In the case of cancer, the therapeutically effective amount may cause any of the changes observable or measurable in a subject as described in the definition of “therapy”, “treatment” and “prophylaxis” above. For example, the effective amount can reduce the number of cancer or tumor cells; reduce the overall tumor size; inhibit or stop tumor cell infiltration into peripheral organs including, for example, the soft tissue and bone; inhibit and stop tumor metastasis; inhibit and stop tumor growth; relieve to some extent one or more of the symptoms associated with the cancer; reduce morbidity and mortality; improve quality of life; or a combination of such effects. An effective amount may be an amount sufficient to decrease the symptoms of a disease responsive to inhibition of ATM kinase activity. For cancer therapy, efficacy in-vivo can, for example, be measured by assessing the duration of survival, time to disease progression (TTP), the response rates (RR), duration of response, and/or quality of life. As recognized by those skilled in the art, effective amounts may vary depending on route of administration, excipient usage, and co-usage with other agents. For example, where a combination therapy is used, the amount of the compound of formula (I) or pharmaceutically acceptable salt described in this specification and the amount of the other pharmaceutically active agent(s) are, when combined, jointly effective to treat a targeted disorder in the animal patient. In this context, the combined amounts are in a “therapeutically effective amount” if they are, when combined, sufficient to decrease the symptoms of a disease responsive to inhibition of ATM activity as described above.

In generally, “therapeutically effective amount” may be determined by one skilled in the art by, for example, starting with the dosage range described in this specification for the compound of formula (I) or pharmaceutically acceptable salt thereof and an approved or otherwise published dosage range(s) of the other pharmaceutically active compound(s).

The method of treating ATM-associated diseases or conditions described in this specification may be used as a monotherapy. As used herein, the term “monotherapy” refers to the administration of a single active or therapeutic compound to a subject in need thereof. In some embodiments, monotherapy will involve administration of a therapeutically effective amount of one of the compounds of the present disclosure, or a pharmaceutically acceptable salt thereof, to a subject in need of such treatment.

Depending upon the particular diseases or conditions to be treated, the method of treating ATM-associated diseases or conditions described in this specification may involve, in addition to administration of the compound of Formula (I), one or more additional therapies, for example, conventional surgery, radiotherapy, chemotherapy, or a combination of such additional therapies. As used herein, the term “combination therapy” refers to the administration of a combination of multiple active compounds.

The additional therapies, such as additional anti-tumor agents, may be administered separately from the compounds of the present disclosure, as part of a multiple dosage regimen. Alternatively, these additional therapies may be part of a single dosage form, mixed with the compounds of the present disclosure in a single composition.

In some embodiments, the compounds of the present disclosure may be administered simultaneously, sequentially or separately to treatment with the conventional surgery, radiotherapy or chemotherapy.

Radiotherapy may include one or more of the following categories of therapy: (i) external radiation therapy using electromagnetic radiation, and intraoperative radiation therapy using electromagnetic radiation; (ii) internal radiation therapy or brachytherapy; including interstitial radiation therapy or intraluminal radiation therapy; or (iii) systemic radiation therapy, including but not limited to iodine 131 and strontium 89.

Chemotherapy may include anti-tumor agents known in the art, for example, antineoplastic agents, antiangiogenic agents, immunotherapy approaches, efficacy enhancers, and the like described in this specification.

Therefore, in one aspect, there is provided a method of treating ATM-associated diseases or conditions in a subject in need thereof, wherein the compound of Formula (I) or pharmaceutically acceptable salts thereof is administered simultaneously, separately or

sequentially with radiotherapy.

In some embodiments, the radiotherapy is brain radiation.

In some embodiments, the ATM-associated disease or condition is cancer. In some embodiments, the cancer is selected from glioblastoma, lung cancer (for example small cell lung cancer or non-small cell lung cancer), breast cancer (for example triple negative breast cancer), head and neck squamous cell carcinoma, oesophageal cancer, cervical cancer and endometrial cancer. In some embodiments, the cancer is glioblastoma. In some embodiment, the cancer is metastatic cancer. In some embodiments, the metastatic cancer is metastases of the central nervous system. In some embodiments, the metastases of the central nervous system is brain metastases.

In some embodiments, there is provided a method of treating glioblastoma in a subject in need thereof, wherein the compound of Formula (I) or pharmaceutically acceptable salts thereof is administered simultaneously, separately or sequentially with brain radiation.

In another aspect, there is provided a method of treating ATM-associated diseases or conditions in a subject in need thereof, wherein the compound of Formula (I) or pharmaceutically acceptable salts thereof is administered simultaneously, separately or sequentially with one or more additional anti-tumor agents.

In some embodiments, the ATM-associated disease or condition is cancer. In certain embodiments, the amounts of the compound of Formula (I), or a pharmaceutically acceptable salt thereof, and the one or more additional anti-tumor agents are jointly effective in producing an anti-cancer effect.

In some embodiments, the additional anti-tumor agent includes antineoplastic agents, antiangiogenic agents, immunotherapy approaches, efficacy enhancers and the like.

In some embodiments, the additional anti-tumor agent is selected from the group consisting of doxorubicin, irinotecan, topotecan, etoposide, mitomycin, bendamustine, chlorambucil, cyclophosphamide, ifosfamide, carmustine, melphalan and bleomycin.

Assay e): ATM SN-38 BT-29 Cellular Potency

*Rationale:*

SN38 is an active metabolite of irinotecan, a topoisomerase-I inhibitor. SN38 causes single strand DNA breaks (SSBs) which are converted to double strand breaks (DSBs) during replication. ATM plays role of repairing DSBs. Inhibition of ATM was evaluated in SN38 treated HT-29 cells (ATCC, Cat # HTB-38) by high-Content Imaging System

*Experimental details:*

HT-29 cells were trypsinized and approximately 10,000 cells were seeded per well to 96-well microplates which were incubated overnight at 37°C and 5% CO<sub>2</sub>. Test compounds were added to the 96-well plates which were incubated at 37°C and 5% CO<sub>2</sub> for 1 hour. SN38 (MCE, Cat# HY-13704) at final concentration of 30nM was then added to the 96-well plates, which were incubated at 37°C and 5% CO<sub>2</sub> for 1 hour. After medium removal, cells were fixed by the addition of 50µl 3.7% formaldehyde in PBSA and incubated for 20 minutes at room temperature. After the plates were rinsed 3 times with PBSA, 50µl permeabilization buffer (0.1% Triton-X 100 in PBSA) was added and the plates were incubated for 20 minutes at room temperature. After the plates were rinsed once with PBSA, 50µl primary antibody solution was added and the plates were incubated in at 4°C overnight. The primary antibody solution was prepared by diluting primary antibody (anti-phospho-ATM (Ser1981) antibody, (Merck Millipore, Cat# 05-740) at 1/10,000th in antibody buffer (3% BSA, 0.05% Tween in PBSA). The plates were rinsed 3 times with PBST (0.05% Tween in PBSA). 50µl secondary antibody solution was added to the plates which were incubated at room temperature for 1 hour away from light. The secondary antibody solution was prepared by diluting secondary antibody (Goat anti-Mouse IgG (H+L) Cross-Adsorbed Secondary Antibody, Alexa Fluor 488, Invitrogen, Cat# A11001) at 1/500th and Hoechst at 1/10,000th in antibody buffer. The plates were rinsed with PBST 3 times and then 100µl PBSA were added per well. The plates were sealed with black plate seals.

### Example 27

#### DMPK and hERG inhibition studies

DMPK and hERG inhibition studies were carried out with the compounds of the present disclosure as well as Reference compound 1, Reference compound 2 (AZD0156) and Reference compound 3 (AZD1390) using the following assays: f) MDCK-MDR1 Pgp assessment, g) Caco-2 BCRP assessment, and h) hERG inhibition assessment.

Assay f): MDCK-MDR1 Pgp assessment

Efflux transport mediated by P-glycoprotein (Pgp) was assessed by MDCK-MDR1 cells. The final concentrations of test compounds and control compound were at 1  $\mu$ M. The multiwell insert plate was incubated at 37 °C for 2 hours.

Assay g): Caco-2 BCRP assessment

Caco-2 cells were used to study efflux transport mediated by BCRP. Rate of drug transport by BCRP was determined in the presence and absence of novobiocin, a strong inhibitor of BCRP, which was added to both apical and basolateral compartments at a final concentration of 30  $\mu$ M. The final concentrations of test compounds and control compound were at 1  $\mu$ M. The multiwell insert plate was incubated at 37 °C for 2 hours. Efflux ratio (-inhibitor/+inhibitor) > 2 was considered to be a BCRP substrate.

Assay h): hERG safety assessment

Inhibition of hERG channel was conducted in HEK 293 cell line stably expressing hERG channel by manual patch clamp.

Results of some representative compounds of the present disclosure and Reference compounds 1-3 in assay f), g), and h) are shown in Table 3.

Table 3: Results of representative compounds and Reference compounds 1-3 in assay f)-h)

From Table 3, it is demonstrated that Reference compound 2 turned out to be a Pgp substrate. Reference compound 3 is not a Pgp substrate, however, it shows significant

hERG inhibition. By comparison, representative compounds of Examples 1 and 3-5 are not Pgp substrate and BCRP substrates, indicating that they are brain penetratable.

Furthermore, compounds of Examples 1 and 3 show significant improvement of hERG liability compared to Reference compound 3.

For the other Example compounds for which the results are not shown, all show similar DMPK and hERG results as the exemplary compounds of Examples 1 and 3-5.

### Example 28

#### AO activity study

AO activity study was carried out with the compounds of the present disclosure and Reference compounds 2, 3, 4 (Zaleplon, an AO assay positive control) and 5 (PF-04217903, a weak AO substrate) using the following assay i) Aldehyde oxidase assay.

#### Assay i): Aldehyde oxidase assay

AO activity was assessed in human liver cytosol. The incubation system was composed of 25 mM phosphate buffer, 1mg/mL human liver cytosol and 0.5 $\mu$ M of test compounds or positive controls. The reaction was stopped at 0.5, 5, 10, 20, 30 and 60 minutes by the addition of 5 volumes of cold acetonitrile with internal standard. Samples were centrifuged at 3, 220 g for 30 minutes. Aliquot of 100  $\mu$ L of the supernatant was mixed with 100  $\mu$ L of ultra-pure H<sub>2</sub>O and then used for LC/MS/MS analysis.

All calculations were carried out using Microsoft Excel. Peak areas were determined from extracted ion chromatograms. The slope value, k, was determined by linear regression of the natural logarithm of the remaining percentage of the parent drug vs. incubation time curve. The in vitro half-life (in vitro  $t_{1/2}$ ) was determined from the slope value using the following equation:

$$\text{in vitro } t_{1/2} = - \{0.693 / k\}$$

Conversion of the in vitro  $t_{1/2}$  (min) into the in vitro intrinsic clearance (in vitro  $CL_{int}$ , in  $\mu$ L/min/mg protein) was done using the following equation (mean of duplicate):

$$\text{in vitro } CL_{int} = \left\{ \frac{0.693}{t_{1/2}} \right\} * \left\{ \frac{\text{volume of incubation } (\mu\text{L})}{\text{amount of proteins (mg)}} \right\}$$

The compounds synthesized in Examples 1-25 and Reference compounds 2-4 were tested in Assay i) as described above. Results of representative compounds of the present disclosure and Reference compounds 2-5 are shown in Table 4.

Table 4: Results of representative compounds and Reference compounds 2-5 in assay i)

Ref. Comp. 2	4.65
Ref. Comp. 3	7.2
Ref. Comp. 4	3.1
Ref. Comp. 5	1.8

It is demonstrated Reference compounds 2 and 3 are shown to be strong AO substrates with intrinsic clearance of 4.65 and 7.2  $\mu\text{L}/\text{min}/\text{mg}$  protein, higher than that of Reference compound 4 (3.1  $\mu\text{L}/\text{min}/\text{mg}$  protein). Reference compound 4 showed high clearance in humans at 16 mL/min/kg corresponding to ~80% liver blood flow (Zientek, M. et al, Drug MetabDispos 2010, 1322-7). In contrast, the compounds of the present disclosure show an

intrinsic clearance lower than that of Reference compound 5 (1.8  $\mu\text{L}/\text{min}/\text{mg}$  protein). Reference compound 5 showed low to moderate clearance in humans at 6  $\text{mL}/\text{min}/\text{kg}$  corresponding to  $\sim 30\%$  liver blood flow. This indicates that the compounds of the present disclosure are not AO substrates.

For the other Example compounds for which the results are not shown, all show intrinsic clearance of no more than 2  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 1.8  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 1.6  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 1.4  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 1.2  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 1  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 0.9  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 0.8  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 0.7  $\mu\text{L}/\text{min}/\text{mg}$  protein, no more than 0.6  $\mu\text{L}/\text{min}/\text{mg}$  protein, or even no more than 0.5  $\mu\text{L}/\text{min}/\text{mg}$  protein.
