INFANT CARE APPARATUS

BACKGROUND OF THE INVENTION

Field of the Invention

[0002] The present invention relates generally to an infant care apparatus and, more particularly, to a seat for an infant or baby that can be moved by a drive mechanism.

Description of Related Art

[0003] Baby swings and bouncy seats have been used to hold, comfort, and entertain infants and babies for many years. Prior art bouncy seats are normally constructed with a wire frame that contains some resistance to deformation that is less than or equal to the weight of the child in the seat. Thus, when the child is placed in the seat, his or her weight causes a slight and temporary deformation in the wire structure that is then counteracted by the wire frame's resistance to deformation. The end result is that the child moves up and down slightly relative to the floor. This motion can be imparted to the seat by a caregiver for the purpose of entertaining or soothing the child.

[0004] Baby swings normally function in much the same way as swing sets for older children; however, the baby swing usually has an automated power-assist mechanism that gives the swing a "push" to continue the swinging motion in much the same way a parent will push an older child on a swing set to keep them swinging at a certain height from the ground.

[0005] There are some products that have recently entered the market that defy easy inclusion into either the bouncy or swing category. One such product includes a motorized motion that can move the infant laterally, but only has a single degree of motorized freedom and is thus limited in the motion profiles that can be generated. While the seat can be rotated so that the baby is moved back and forth in a different orientation, there remains only one possible motion profile.

[0006] A need exists for a motorized infant chair that is capable of simultaneous or independent movement in two dimensions, and can reproduce a large number of motion profiles with those two dimensions to both better mimic the motion of a parent or caregiver.

SUMMARY OF THE INVENTION

[0007] Described herein is a motorized infant chair that is capable of simultaneous or independent movement in at least two dimensions, and can reproduce a large number of motion profiles with those at least two dimensions to better mimic the motion of a parent or caregiver.

[0008] Accordingly, in one embodiment, an infant care apparatus includes a base; a drive mechanism coupled to the base; a controller electronically coupled to the drive mechanism; and a support device coupled to the drive mechanism. The support device is configured to be moved in both a horizontal and vertical direction relative to the base by the drive mechanism. The drive mechanism is controlled by the controller to move the support device in a plurality of motion profiles relative to the base.

[0009] The controller may be mounted within the base, and may include a user interface configured to receive input from the user for controlling the movement of the drive mechanism. Each of the plurality of motion profiles may include both horizontal and vertical movements.

[0010] The drive mechanism may include a horizontal reciprocating assembly and a vertical reciprocating assembly disposed on the horizontal reciprocating assembly. The horizontal reciprocating assembly may include a first motor having a drive shaft; a slide crank assembly comprising a gearing assembly coupled to the drive shaft of the first motor and a crank member coupled to the gearing assembly; and a sliding stage coupled to the crank member. Operation of the first motor may cause rotation of the slide crank assembly, thereby imparting reciprocating horizontal motion to the sliding stage. The vertical reciprocating assembly includes a second motor having a drive shaft; a worm gear assembly coupled to the output of the drive shaft; and a vertical yoke having a first end coupled to an output shaft of the worm gear assembly. Operation of the second motor may cause rotation of the vertical yoke, thereby imparting reciprocating vertical motion to the support device. The vertical reciprocating assembly may further include a dual scissor mechanism coupled to a second end of the vertical yoke configured to support the support device.

[0011] Accordingly, the first motor provides horizontal motion to the support device and the second motor provides vertical motion to the support device. A first encoder having a single slot may be coupled to a drive shaft of the first motor and a second encoder having a single slot may be coupled to the drive shaft of the second motor. The controller may determine position information of the support device based at least in part on information

from the first encoder and the second encoder. The control system may also include two positional sensors to indicate when the vertical reciprocating assembly is in its lowest position and when the horizontal reciprocating assembly is at its furthest point to the right when viewed from the front.

[0012] The support device may include a seat support tube coupled to the drive mechanism; a substantially elliptical seating portion coupled to a first end and a second end of the seat support tube; and a toy bar having a first end coupled to the second end of the seat support tube and a second end extending over the seating portion. The position of the seating portion of the support device may be adjusted by sliding the seat support tube within the drive mechanism and locking the seat support tube in a desired position. The first end of the toy bar may include a curved surface that corresponds to a curved surface of the second end of the seat support tube, thereby causing the second end of the toy bar to be centered over the seating portion when the first end of the toy bar is coupled to the second end of the seat support tube.

[0013] Further disclosed is a method of controlling an infant care apparatus. The method may include the steps of providing an infant care apparatus having a base, a drive mechanism coupled to the base, a controller electronically coupled to the drive mechanism, and a support device coupled to the drive mechanism; providing a first encoder coupled to a drive shaft of a first motor of the drive mechanism; and providing a second encoder coupled to a drive shaft of a second motor of the drive mechanism. The first motor is configured to provide horizontal movement to the drive mechanism, and the second motor is configured to provide vertical movement to the drive mechanism. The method also includes the steps of transmitting positional information from the first and second encoders to the controller; determining the position of the drive mechanism based on the positional information; and moving the support device in at least one motion profile relative to the base.

[0014] The first encoder and the second encoder may each include no more than one slot. Each of the plurality of motion profiles may include movement of the support device in a horizontal directional and a vertical direction relative to the base. The movement of the support device in the horizontal direction and the movement of the support device in the vertical direction may be coordinated such that a repeatable, visually distinctive motion profile is obtained.

[0015] The support device may be moved relative to the base in a plurality of motion profiles. Each of the plurality of motion profiles may be predetermined and one of the

plurality of motion profiles is selected by a user. A speed of the first motor and the second motor may be adjustable by the controller.

[0016] Also disclosed is an infant care apparatus that includes a drive mechanism and a support device coupled to the drive mechanism. The drive mechanism is configured to move the support device in a plurality of motion profiles each comprising both vertical and horizontal movement of the support device.

[0017] Further disclosed is an infant care apparatus that includes a base; a drive mechanism coupled to the base; a controller electronically coupled to the drive mechanism; and a support device coupled to the drive mechanism. The support device is configured to be moved in both a horizontal and vertical direction relative to the base by the drive mechanism. The movements of the support device in the horizontal and vertical directions are independently controlled by the controller.

[0018] Movements of the support device in the horizontal and vertical directions may be coordinated to obtain at least one motion profile. The support device may be moved in the vertical direction a maximum of about 1.5 inches and the support device may be moved in the horizontal direction a maximum of about 3.0 inches. Movement in the vertical direction may have a frequency range of between about 10 and 40 cycles per minute and movement in the horizontal direction may have a frequency range of between about 10 and 40 cycles per minute.

[0019] These and other features and characteristics of the present invention, as well as the methods of operation and functions of the related elements of structures and the combination of parts and economies of manufacture, will become more apparent upon consideration of the following description and the appended claims with reference to the accompanying drawings, all of which form a part of this specification, wherein like reference numerals designate corresponding parts in the various figures. It is to be expressly understood, however, that the drawings are for the purpose of illustration and description only and are not intended as a definition of the limits of the invention. As used in the specification and the claims, the singular form of "a", "an", and "the" include plural referents unless the context clearly dictates otherwise.

BRIEF DESCRIPTION OF THE DRAWINGS

[0020] **FIG. 1** is a perspective view of an infant care apparatus in accordance with one embodiment;

[0021] **FIG. 2** is a side view of the infant care apparatus of **FIG. 1**;

[0022] **FIG. 3** is a rear view of the infant care apparatus of **FIG. 1**;

[0023] **FIG. 4** is a top plan view of the infant care apparatus of **FIG. 1**;

[0024] **FIG. 5** is a cross-sectional view of a portion of the infant care apparatus of **FIG. 1**;

[0025] **FIG. 6** is a perspective view of the infant care apparatus of **FIG. 1** with a seat frame, seat support plate, drive mechanism cover, and top base cover removed illustrating both the horizontal and vertical reciprocating assemblies;

[0031] **FIG. 12** is a perspective view of a portion of **FIG. 11** enlarged for magnification purposes;

[0032] **FIGS. 13A** through **13E** are illustrative diagrams of five representative motion profiles of the present invention; and

[0033] **FIG. 14** is a block diagram of an exemplary control system for use with the infant care apparatus of the present invention.

DETAILED DESCRIPTION OF THE PRESENT INVENTION

[0034] For purposes of the description hereinafter, the terms "upper", "lower", "right", "left", "vertical", "horizontal", "top", "bottom", "lateral", "longitudinal", and derivatives thereof shall relate to the invention as it is oriented in the drawing figures. However, it is to be understood that the invention may assume alternative variations and step sequences, except where expressly specified to the contrary. It is also to be understood that the specific devices and processes illustrated in the attached drawings, and described in the following specification, are simply exemplary embodiments of the invention. Hence, specific

dimensions and other physical characteristics related to the embodiments disclosed herein are not to be considered as limiting.

[0035] An infant care apparatus according to one embodiment is shown in **FIGS. 1-14**.

[0036] With reference to **FIGS. 1-4**, an infant care apparatus, denoted generally as reference numeral **1**, includes a base **3**, a drive mechanism positioned within a drive mechanism housing **5** disposed on base **3**, and a support device 7 coupled to drive mechanism housing **5**. Support device 7 includes a seating portion **9** and a seat support tube **11**. Seating portion **9** has a generally elliptical shape having an upper end **13** and a lower end **15** when viewed from above. Seating portion **9** is also shaped to resemble a sinusoidal waveform when viewed from the side as illustrated in **FIG. 2**.

[0037] Seating portion **9** is designed to receive a fabric or other type of comfortable seat **17** for an infant as shown in phantom in **FIG. 2**. Seat **17** may be coupled to seating portion **9** using zippers, hook and loop fabric, buttons, or any other suitable fastening mechanism. In addition, seat **17** may further include a strap **19** to secure a baby or infant to seat **17** as is well known in the art. Strap **19** is riveted to seat support tube **11** with clips provided on a strap securing member **21**. Strap **19** is fed through slots (not shown) provided in seat **17** to connect into the crotch support (not shown) of seat **17** to secure the child. By securing strap **19** to seat support tube **11**, the baby or infant positioned on seat **17** is prevented from leaning forward and falling out of seat **17**. In addition, strap **19** can be easily removed from strap securing member **21** by a parent or care provider so that seat **17** can be removed for cleaning or replacement. Seat **17** is desirably manufactured in a variety of colors and patterns such that a parent or care provider can change the aesthetic look of infant care device **1** by interchanging seat **17** without replacing infant care device **1**.

[0038] Seat support tube **11** is connected to upper end **13** of seating portion **9** via an upper connector **23** and curvedly extends away from the upper connector **23** toward lower end **15** of seating portion **9** where it is coupled to a lower connector **25**. With reference to **FIG. 5**, and with continued reference to **FIGS. 1-4**, seat support tube **11** is supported by, and slidingly engaged with, a curved passage **27** in an upper portion **29** of drive mechanism housing **5** between upper connector **23** and lower connector **25**. A rear recline locker **31** and forward recline locker **33** are also positioned within upper portion **29** of drive mechanism housing **5**. Rear recline locker **31** and forward recline locker **33** each include a locking pad **35**. Locking pads **35** are manufactured from rubber or any other suitable material. Rear recline locker **31** and forward recline locker **33** are configured to removeably engage locking pads **35** with the portion of seat support tube **11** positioned within curved passage **27** by movement of a

camming mechanism **37** extending from upper portion **29** of drive mechanism housing **5**. Camming mechanism **37** is mechanically coupled to rear recline locker **31**, and rear recline locker **31** is coupled to front recline locker **33** by a linkage **39** such that movement of camming mechanism **37** causes movement of both rear recline locker **31** and forward recline locker **33**.

[0039] In operation, a user pushes up on camming mechanism **37** and slides seat support tube **11** within curved passage **27** until a desired position for seating portion **9** is reached. The user then pushes down on camming mechanism **37** causing rear recline locker **31** to move forward and forward recline locker **33** to move back. This has the effect of sandwiching seat support tube **11** between an upper surface of curved passage **27** and locking pads **35** of rear recline locker **31** and forward recline locker **33**. This allows the orientation of seating portion **9** to be easily altered for the comfort of the infant or baby seated therein. A seat recline security switch **40** (*see* **FIG. 6**) is provided to detect whether a user has correctly locked seating portion **9** using camming mechanism **37**. If the user has failed to correctly lock seating portion **9**, a message will be displayed on a display **56** of a control panel **53** and the user will be prevented from starting infant care apparatus **1**.

[0040] In addition, a toy bar **41** is also provided as shown in **FIGS. 1-4**. Toy bar **41** includes a first end **43** coupled to upper connector **23** and a second end **45** extending over seating portion **9**. Second end **45** of toy bar **41** may include a toy hanger **47** disposed thereon for mounting one or a plurality of toys (not shown) to entertain the infant. First end **43** of toy bar **41** has a curved surface **49** that corresponds to a curved surface **51** of second end **45** of seat support tube **11** (*see* **FIG. 3**), thereby causing second end **45** of toy bar **41** to be centered over seating portion **9** when first end **43** of toy bar **41** is coupled to second end **45** of seat support tube **11**.

[0041] Base **3** includes a bottom support housing **50** with a top enclosure **52** positioned over and covering bottom support housing **50**. The drive mechanism is supported on bottom support housing **50** and extends from an opening **54** in top enclosure **52**. Base **3** houses control panel **53** coupled to a controller for viewing and controlling the speed and motion of the drive mechanism as will be described in greater detail hereinafter. Base **3** may further include a portable music player dock **55**, with speakers **57** and an input jack **58**, for playing music or other pre-recorded soothing sounds. Control panel **53** may also have display **56** to provide information to the user as to motion profile, volume of music being played through speakers **57**, and speed of the reciprocation motion, for example.

[0042] With reference to **FIGS. 6-7**, and with continuing reference to **FIGS. 1-5**, infant care apparatus **1** further includes a drive mechanism, denoted generally as reference numeral **59**, supported by bottom support housing **50** of base **3** and positioned at least partially within drive mechanism housing **5**. Drive mechanism **59** includes a horizontal reciprocating assembly **61** for providing horizontal motion and a vertical reciprocating assembly **63** for providing vertical motion.

[0043] Horizontal reciprocating assembly **61** includes a rigid platform **65**. Rigid platform **65** is generally I-shaped having top and bottom sides **67** and **69**, respectively, and left and right sides **71** and **73**, respectively. Top side **67** of rigid platform **65** includes at least one grooved wheel **75**, and preferably two grooved wheels **75**, similar in function and appearance to a pulley wheel, suitably disposed thereon such that top side **67** of rigid platform **65** is rollingly supported by grooved wheels **75**. A rail 77 is fixably attached to bottom support housing **50** of base **3**. Rail 77 rollingly receives grooved wheels **75** on top side **67** of rigid platform **65**. Bottom side **69** of rigid platform **65** includes at least one wheel **76**, and preferably two wheels **76**, suitably disposed thereon such that bottom side **69** of rigid platform **65** is rollingly supported by wheels **76**. A slot **78** is provided to rollingly receive wheels **76** on bottom side **69** of rigid platform **65**. Top side **67** is provided with grooved wheels **75** positioned on a rail 77 while bottom side **69** is provided with wheels **76** positioned within a slot **78** to account for any manufacturing error in rigid platform **65**. If rigid platform **65** is too long or short, wheels **76** will "float" a slight amount within slot **78** to account for this manufacturing error. Thus, in a preferred embodiment, horizontal reciprocating assembly **61** is capable of rolling back and forth along rail 77 and slot **78**, thereby allowing a horizontal displacement of the horizontal reciprocating assembly **61** of approximately three inches.

[0044] Horizontal reciprocating assembly **61** further includes a first motor **79** having a drive shaft **81** mounted to bottom support housing **50** and a slide crank assembly, denoted generally as reference numeral **83**, also mounted to bottom support housing **50**. Slide crank assembly **83** includes a gearing assembly having a set of first gears **85** operationally coupled to drive shaft **81** of first motor **79** and a large second gear **87** operationally coupled to first gears **85**. Slide crank assembly **83** further includes a crank member **89** having a first end **91** and a second end **93**. First end **91** of crank member **89** is rotationally coupled to a point on the outer circumference of second gear **87**, and second end **93** of crank member **89** is fixedly coupled to a point approximately in the center of left side **71** of rigid platform **65**. In operation, actuation of first motor **79** causes rotation of first gears **85** which in turn causes rotation of second gear **87**. The rotation of second gear **87** causes crank member **89** to either

push or pull rigid platform **65** depending on the position of crank member **89**. This operation effects a reciprocating horizontal movement of rigid platform **65**, along with everything mounted thereon, back and forth along rails 77. Accordingly, this system allows a single motor (*i.e.*, first motor **79**) to move rigid platform **65** back and forth with the motor only running in a single direction, thereby eliminating backlash in the system. The system for controlling horizontal reciprocating assembly **61** to achieve the desired motion profile will be discussed in greater detail hereinafter.

[0045] With reference to **FIGS. 8-12**, and with continuing reference to **FIGS. 1-7**, vertical reciprocating assembly **63** is positioned on rigid platform **65** and is configured to provide vertical movement to support device 7. Vertical reciprocating assembly **63** includes a double scissor mechanism having a first double scissor mechanism **95** operatively coupled to a second double scissor mechanism **97** such that their movement is synchronized. First scissor mechanism **95** and second scissor mechanism **97** are attached between rigid platform **65** and a support platform **99**. Various links of left and right double scissor mechanisms **95**, **97** have been omitted in **FIGS. 8**, **9**, **11**, and **12** for purposes of clarity, however the complete structure of one side of the double scissor mechanism is provided in **FIG. 10**.

[0046] First double scissor mechanism **95** includes a first pair of spaced-apart parallel members **101**, **101'** and a second pair of spaced-apart parallel members **103**, **103'**. Second double scissor mechanism **97** includes a third pair of spaced-apart parallel members **105**, **105'** and a fourth pair of spaced-apart parallel members **107**, **107'**.

[0047] Lower ends **101L** of the first pair of spaced-apart parallel members **101**, **101'** and lower ends **107L** of the fourth pair of spaced-apart parallel members **107**, **107'** are rotatably pinned to each other and to rigid platform **65**. Likewise, upper ends **103U**, **103U'** of second pair of spaced-apart parallel members **103**, **103'**, and upper ends **105U**, **105U'** of third pair of spaced-apart parallel members **105**, **105'** are rotatably pinned to each other and to the supporting platform **99**.

[0048] First and second horizontal bars **109**, **111** are provided and extend transversely between lower ends of second pair of spaced-apart parallel members **103**, **103'**, and between lower ends of third pair of spaced-apart parallel members **105**, **105'**, respectively, for additional structural stability. In addition, first and second horizontal bars **109**, **111** may further include bearing wheels **113** at their ends for supporting vertical reciprocating assembly **63** and supporting platform **99** and allowing smooth translational movement of first and second horizontal bars **109**, **111** during operation.

[0049] Still further, third and fourth horizontal bars **115**, **117** extend transversely between the upper ends **101U**, **101U'** of the first pair of spaced-apart parallel members **101**, **101'**, and the upper ends **107U**, **107U'** of the fourth pair of spaced-apart parallel members **107**, **107'**, respectively. Third and fourth horizontal bars **115**, **117** include bearing wheels **119** at their ends for supporting support platform **99**.

[0050] First pair of spaced-apart parallel members **101**, **101'** is pivotally secured at a central portion thereof to second pair of spaced-apart parallel members **103**, **103'** via horizontal pivot pins, or the like. Correspondingly, third pair of spaced-apart parallel members **105**, **105'** is also pivotally secured at their respective central portions to fourth pair of spaced-apart parallel members **107**, **107'** via horizontal pivot pins, or the like.

[0051] As a consequence of the foregoing description of the double scissor mechanism, when supporting platform **99**, which is designed to support seating portion **9**, is displaced in a vertically upward direction, both front and rear supporting and non-supporting members move in crossed fashion relative to the pivot pins such that the double scissor mechanism extends between rigid platform **65** and the upwardly displaced supporting platform **99** as illustrated by the successively increased supporting platform **99** height in **FIGS. 8**, **10**, and **11**.

[0052] Additionally, vertical reciprocating assembly **63** may be provided with at least one, and preferably two, resistive mechanical elements **123**, such as a tension spring, fixably attached between lower ends **103L** of second pair of spaced-apart parallel members **103**, **103'** and the lower ends **105L** of third pair of spaced-apart parallel members **105**, **105'** whereby the upward vertical motion of vertical reciprocating assembly **63** is assisted by resistive mechanical element **123** because it pulls the relevant portions of the double scissor mechanism toward each other. The position of restrictive mechanical element **123** described above is not to be construed as limiting as the exact location of the attachment of resistive mechanical element **123** to the double scissor mechanism can be varied with similar results so long as it is attached to portions that get closer together as supporting platform **99** rises away from base **3** and it is attached in a way that assists that movement. Resistive mechanical element **123** also has the benefit of counteracting the effects of gravity because it acts to reduce downward movement when properly placed.

[0053] In yet another aspect, the resistive mechanical element **123** comprises a compression spring (not shown) placed in an advantageous position relative to vertical reciprocating assembly **63**, such as between rigid platform **65** and supporting platform **99** in

order to assist vertical expansion of the double scissor mechanism and resist vertical contraction of the double scissor mechanism.

[0054] With continued reference to **FIGS. 8-12**, a second motor **125** is mounted on rigid platform **65**. Second motor **125** includes a drive shaft **127** operationally coupled to a worm gear drive assembly **129**. Worm gear drive assembly **129** converts rotation of drive shaft **127** to a rotational movement of an output member **131** that is perpendicular to the rotation of drive shaft **127**. A vertical yoke **133** is rotatably attached at a first end **135** thereof to output member **131** in a manner such that vertical yoke **133** raises and lowers an attachment member **137** attached to a second end **139** thereof along an axis **y** shown in **FIG. 10**. Attachment member **137** is fixedly coupled to supporting platform **99**. Accordingly, this system allows a single motor (*i.e.*, second motor **125**) to move supporting platform **99** up and down with the motor only running in a single direction, thereby eliminating backlash in the system. The system for controlling vertical reciprocating assembly **63** to achieve the desired motion profile will be discussed in greater detail hereinafter. While vertical reciprocating assembly **63** has been illustrated and described herein as a double scissor mechanism, those skilled in the art will recognize that there are many other configurations to accomplish the same goal.

[0055] With reference to **FIGS. 13A-13E**, and with continued reference to **FIGS. 1-12**, a control system is provided to operatively control drive mechanism **59** so that it can move in at least one motion profile and, desirably, a plurality of pre-programmed motion profiles such as Car Ride **200**, Kangaroo **202**, Ocean Wave **204**, Tree Swing **206**, and Rock-A-Bye **208**, as examples. These motion profiles are obtained by independently controlling the horizontal movement provided by horizontal reciprocating assembly **61** and the vertical movement provided by vertical reciprocating assembly **63** and then coordinating the horizontal and vertical movements to obtain visually distinctive motion profiles. However, these motion profiles are for exemplary purposes only and are not to be construed as limiting as any motion profile including horizontal and/or vertical motions may be utilized.

[0056] The control system of infant care apparatus **1** includes a controller, such as a microprocessor, a rheostat, a potentiometer, or any other suitable control mechanism, one or a plurality of control switches or knobs **141** for causing actuation of drive mechanism **59**, and a variety of inputs and outputs operatively coupled to the controller. Since horizontal reciprocating assembly **61** and vertical reciprocating assembly **63** each include its own motor **79** and **125**, respectively, horizontal reciprocating assembly **61** can be controlled independently of vertical reciprocating assembly **63** to obtain a variety of motion profiles that include both horizontal and vertical motion.

[0057] The control system desirably includes a variety of input sensors. For example, the control system may include a horizontal encoder **143** coupled to a back shaft **145** of first motor **79**. Horizontal encoder **143** may include an infrared (IR) sensor **147** and a disk **149** with single hole or slot **151** positioned thereon (*see* **FIG. 7**). Horizontal encoder **143** allows the controller to determine the speed and number of revolutions of first motor **79**. A vertical encoder **153** may also be provided and is configured to be coupled to a back shaft **155** of second motor **125**. Vertical encoder **153** may include an IR sensor **157** and a disk **159** with single hole or slot **161** positioned thereon (*see* **FIG. 11**). Vertical encoder **153** allows the controller to determine the speed and number of revolutions of second motor **125** easily and inexpensively.

[0058] Horizontal and vertical limit switches **165**, **167** may also be provided to provide inputs to the controller that rigid platform **65** has passed over an end of travel and that supporting platform **99** has passed over an end of travel, respectively. In addition, vertical limit switch **167** indicates when vertical reciprocating assembly **63** is in its lowest position and horizontal limit switch **165** indicates when horizontal reciprocating assembly **61** is at its furthest point to the right when viewed from the front. Horizontal and vertical limit switches **165**, **167** allow the control system to quickly determine the initial position of the horizontal reciprocating assembly **61** and the vertical reciprocating assembly **63** and to adjust for error in drive mechanism **59** as discussed in greater detail hereinafter. These limit switches **165**, **167** may be embodied as optical switches.

[0059] An overcurrent protection circuit detection input (not shown) may also be provided to the controller in order to prevent the electronics from being damaged. For instance, if too much current is drawn, circuitry may be provided that diverts power from second motor **125** if current exceeds a threshold. Additional circuitry detects whether this protection circuit has been tripped. Finally, control switches **141** may include user input buttons such as a main power button, a start/stop button, a motion increment button, a motion decrement button, a speed increment button, a speed decrement button, and the like.

[0060] The controller of the control system may also include a variety of outputs. These outputs include, but are not limited to: (1) Pulse Width Modulation (PWM) for first motor **79**, (2) PWM for second motor **125**, (3) display **56** backlight, which can be turned on and off independently in order to conserve power, (4) display **56** segments, and (5) power to IR lights of IR sensors **147**, **157** of encoders **143**, **153**, which can be turned on and off to conserve power when infant care apparatus **1** is not in use.

[0061] The following explanation provides an understanding of an exemplary control system of infant care apparatus **1**. Based on the physical limitations of first and second motors **79**, **125** of horizontal and vertical reciprocating assemblies **61**, **63**, the maximum speed of first motor **79** may be about a four second period and the maximum speed of second motor **125** may be about a two second period. Based on these constraints, the following relationships may be established:

Table 1

	Car Ride	Kangaroo	Tree Swing	Rock-a-Bye	Ocean Wave
Number of Vertical Cycles per Horizontal Cycle (n)	2	4	2	2	1
Phase offset (Φ)	90 degrees	0 degrees	180 degrees	0 degrees	90 degrees
Horizontal period at min speed	8 seconds	12 seconds	8 seconds	8 seconds	8 seconds
Horizontal period at max speed	4 seconds	8 seconds	4 seconds	4 seconds	4 seconds

[0062] The speed of first motor **79** is independently set to a correct period and a feedback control loop is used to ensure that first motor **79** remains at a constant speed despite the dynamics of the components of infant care apparatus **1**. As mentioned above, the output of the control system is a PWM signal for first motor **79**. One possible input for the control system is velocity of first motor **79**, which can be observed from the speed of first motor **79** as observed by horizontal encoder **143**. However, in order to avoid computationally expensive calculations, it is possible to operate in the frequency domain and use the number of processor ticks between ticks of horizontal encoder **143** as the input variable. This allows the calculations of the controller to be limited to integers rather than manipulating floats.

[0063] The physical drive mechanism of horizontal reciprocating assembly **61** is slide crank assembly **83** as described in greater detail hereinabove. Slide crank assembly **83** allows a single motor (*i.e.*, first motor **79**) to slide rigid platform **65** back and forth without the need to change directions. Since first motor **79** is only required to run in one direction, the effect of backlash is eliminated in the system, thereby removing problems with horizontal encoder **143** on back shaft **145** of first motor **79**.

[0064] It is known that the natural soothing motions a person uses to calm a baby are a combination of at least two motions that each move in a reciprocating motion that has a smooth acceleration and deceleration such that the extremes of the motion slow to a stop before reversing the motion and are fastest in the middle of the motion. This motion is the

same as that generated from a sinusoidal motion generated from the combination of the slide crank assembly **83** and the worm gear drive assembly **129**. Slide crank assembly **83** and worm gear drive assembly **129** allow the driving motors to run at a constant rotational speed while the output motion provided to seat portion **9** slows and speeds up, mimicking the motion of a person soothing a child. These assemblies also allow the driving motors to run in one direction.

[0065] With reference to **FIG. 14**, the torque on first motor **79** depends on the friction of the entire system (which is dependent on weight) and the angle of crank member **89**. The torque of first motor **79** is controlled by setting the PWM to a predetermined value based on the desired velocity set by the user. A PID controller **163** with feed forward compensation can be used to control the velocity of first motor **79**.

[0066] Any of the components shown in **FIG. 14** may be set to zero. For example, reasonable accuracy is achieved using only proportional and integral terms where the constants K_p and K_i are dependent on the input speed, ignoring the feed forward and derivative terms.

[0067] Based on the feedback from horizontal encoder **143** and horizontal limit switch **165**, the exact position of rigid platform **65** (denoted "hPos") can be determined at any point in its range of motion. Similarly, based on feedback from vertical encoder **153** and vertical limit switch **167**, the exact position of supporting platform **99** (denoted "vPos") can be determined at any point in its range of motion.

[0068] While the control of rigid platform **65** is based entirely on velocity, the control of supporting platform **99** is based upon both position and velocity. For a given horizontal position (hPos) and a given motion, which dictates the number of vertical cycles per horizontal cycles (n) and phase offset (Φ) as shown in Table 1, the desired vPos can be calculated as follows:

$$Desired\_vPos = hPos \times v2h\_ratio \times n + \Phi \qquad \text{(Equation 1)}$$

[0069] where v2h_ratio is a constant defined as the number of vertical encoder ticks per cycle divided by the number of horizontal encoder ticks per cycle. Based on the actual vertical position, the amount of error can be calculated as follows:

$$posErr = vPos - Desired\_vPos \qquad \text{(Equation 2)}$$

[0070] This error term must be correctly scaled to +/- verticalEncoderTicksPerCycle/2.

[0071] As an aside, if the direction of motion in Ocean Wave **204** and Car Ride **200** is irrelevant, there are two possibilities for Desired_vPos for each value of hPos and we can base the vertical error term, posErr, on the closer of the two.

[0072] The positional error term, posErr, must then be incorporated into a velocity based feedback control loop. Logically, if the vertical axis is behind (posErr < 0), velocity should be increased while if the vertical axis is ahead (posErr > 0), velocity should be decreased in proportion to the error as follows:

$$vSP = posErr \times K_{vp} + vBase \qquad \text{(Equation 3)}$$

[0073] where

$$vBasw = \frac{hSP}{n} \times h2v\_ratio \qquad \text{(Equation 4)}$$

and h2v_ratio is defined as the horizontal ticks per cycle/vertical ticks per cycle.

[0074] The above description is for exemplary purposes only as any suitable control scheme may be utilized. Many possible improvements can be made to this logic. For example, if the control system is too far behind to catch up within some threshold, the controller may be programmed to slow down the vertical axis instead of speeding up. Alternatively, in some situations, it may be desirable to slow down the horizontal axis until the vertical axis is able to synchronize. In addition, while horizontal encoder **143** and vertical encoder **153** were described hereinabove, this is not to be construed as limiting as magnetic encoders, as well as other types of encoders well known in the art may also be used. It may also be desirable to provide an arrangement in which two or more control switches associated with respective motors are required to both be actuated to effect speed control in the desired direction. Furthermore, while it was described that horizontal encoder **143** and vertical encoder **153** only include a single slot, this is not to be construed as limiting as encoders with a plurality of slots may be utilized. However, this disclosure advantageously uses single slot encoders to obtain high resolution feedback while lowering manufacturing costs.

[0075] In an exemplary embodiment, infant care apparatus **1** is configured to reciprocate the seat with a vertical displacement of 1.5 inches and a horizontal displacement of 3.0 inches with a vertical displacement frequency range of between about 10 and 40 cycles per minute and a horizontal displacement frequency range of between about 10 and 40 cycles per minute.

[0076] In another aspect, a third reciprocation means (not shown) may be added to enable reciprocation of the seat in a third direction orthogonal to the horizontal and vertical directions referenced herein. In one such embodiment, an additional platform would be placed either above or below the horizontal reciprocating assembly **61** to reciprocate the

entire drive mechanism **59** in a horizontal direction that is perpendicular to the movement of horizontal reciprocating assembly **61**. Using another slide crank assembly drawing power from either an existing motor or an additional motor, infant care apparatus **1** provides three-dimensional movement for an infant, opening up a multitude of additional motion profiles such as mimicking the motion of a traditional swing, for example.

[0077] Although an infant care apparatus has been described in detail for the purpose of illustration based on what is currently considered to be the most practical and preferred embodiments, it is to be understood that such detail is solely for that purpose and that the invention is not limited to the disclosed embodiments, but, on the contrary, is intended to cover modifications and equivalent arrangements. For example, it is to be understood that this disclosure contemplates that, to the extent possible, one or more features of any embodiment can be combined with one or more features of any other embodiment.

CLAIMS

1. An infant care apparatus comprising:

a base;

a drive mechanism coupled to the base, the drive mechanism comprising a horizontal reciprocating assembly; and a vertical reciprocating assembly disposed on the horizontal reciprocating assembly;

a controller electronically coupled to the drive mechanism; and

a support device coupled to the drive mechanism, the support device configured to be moved in both a horizontal direction relative to the base by the horizontal reciprocating assembly and a vertical direction relative to the base by the vertical reciprocating assembly,

wherein the drive mechanism is controlled by the controller to move the support device in a plurality of visually distinctive motion profiles relative to the base that are obtained by independently controlling, by the controller, horizontal movement provided by the horizontal reciprocating assembly and vertical movement provided by a vertical reciprocating assembly and then coordinating, by the controller, the horizontal and vertical movements to obtain the plurality of visually distinctive motion profiles.

2. The infant care apparatus of claim 1, wherein the controller is mounted within the base.

3. The infant care apparatus of claim 2, wherein the controller includes a user interface configured to receive input from the user for controlling the movement of the drive mechanism.

4. The infant care apparatus of claim 1, wherein the horizontal reciprocating assembly comprises:

a first motor having a drive shaft;

a slide crank assembly comprising a gearing assembly coupled to the drive shaft of the first motor and a crank member coupled to the gearing assembly; and

a sliding stage coupled to the crank member,

wherein operation of the first motor causes rotation of the slide crank assembly, thereby imparting reciprocating horizontal motion to the sliding stage.

5. The infant care apparatus of claim 1, wherein the vertical reciprocating assembly comprises:

a second motor having a drive shaft;

a worm gear assembly coupled to an output of the drive shaft; and

a vertical yoke having a first end coupled to an output shaft of the worm gear assembly,

wherein operation of the second motor causes rotation of the vertical yoke, thereby imparting reciprocating vertical motion to the support device.

6. The infant care apparatus of claim 5, wherein the vertical reciprocating assembly further includes a dual scissor mechanism coupled to a second end of the vertical yoke configured to support the support device.

7. The infant care apparatus of claim 1, further comprising a first motor for providing horizontal motion to the support device and a second motor for providing vertical motion to the support device.

8. The infant care apparatus of claim 7, wherein a first encoder having a single slot is coupled to a drive shaft of the first motor and a second encoder having a single slot is coupled to the drive shaft of the second motor.

9. The infant care apparatus of claim 8, wherein the controller determines position information of the support device based at least in part on information from the first encoder and the second encoder.

10. The infant care apparatus of claim 1, wherein the support device comprises:

a seat support tube coupled to the drive mechanism;

a substantially elliptical seating portion coupled to a first end and a second end of the seat support tube; and

a toy bar having a first end coupled to the second end of the seat support tube and a second end extending over the seating portion.

11. The infant care apparatus of claim 10, wherein the position of the seating portion of the support device is adjustable by sliding the seat support tube within the drive mechanism and locking the seat support tube in a desired position.

12. The infant care apparatus of claim 10, wherein the first end of the toy bar includes a curved surface that corresponds to a curved surface of the second end of the seat support tube, thereby causing the second end of the toy bar to be centered over the seating portion when the first end of the toy bar is coupled to the second end of the seat support tube.

13. A method of controlling an infant care apparatus comprising:

providing an infant care apparatus comprising:

a base;

a drive mechanism coupled to the base, the drive mechanism comprising a horizontal reciprocating assembly; and a vertical reciprocating assembly disposed on the horizontal reciprocating assembly;

a controller electronically coupled to the drive mechanism; and

a support device coupled to the drive mechanism;

providing a first encoder coupled to a drive shaft of a first motor of the horizontal reciprocating assembly of the drive mechanism, the first motor configured to provide horizontal movement to the drive mechanism;

providing a second encoder coupled to a drive shaft of a second motor of the vertical reciprocating assembly of the drive mechanism, the second motor configured to provide vertical movement to the drive mechanism;

transmitting positional information from the first and second encoders to the controller;

determining the position of the drive mechanism based on the positional information; and

moving the support device in at least one motion profile relative to the base.

14. The method of claim 13, wherein the first encoder and the second encoder each include no more than one slot.

15. The method of claim 13, wherein the at least one motion profile includes movement of the support device in a horizontal direction and a vertical direction relative to the base.

16. The method of claim 15, wherein the movement of the support device in the horizontal direction and the movement of the support device in the vertical direction is coordinated such that a repeatable, visually distinctive motion profile is obtained.

17. The method of claim 13, wherein the support device is moved relative to the base in a plurality of motion profiles.

18. The method of claim 17, wherein each of the plurality of motion profiles is predetermined and one of the plurality of motion profiles is selected by a user.

19. The method of claim 13, wherein a speed of the first motor and the second motor is adjustable by the controller.

20. An infant care apparatus comprising:

a base;

a drive mechanism positioned within a drive mechanism housing disposed on the base;

a support device coupled to the drive mechanism, the support device comprising a seating portion and an arcuate seat support tube extending from an upper end of the seating

portion to a lower end of the seating portion, the seat support tube is supported by, and slidingly engaged with, a curved passage of the drive mechanism housing; and

wherein the drive mechanism is configured to move the support device in a plurality of motion profiles each comprising both vertical and horizontal movement of the support device.

21. An infant care apparatus comprising:

a base;

a drive mechanism coupled to the base;

a controller electronically coupled to the drive mechanism; and

a support device coupled to the drive mechanism, the support device configured to be moved in both a horizontal and vertical direction relative to the base by the drive mechanism,

wherein movement of the support device in the horizontal and vertical directions is independently controlled by the controller and then the movement of the support device in the horizontal and vertical directions is coordinated by the controller to obtain a plurality of visually distinctive motion profiles.

22. The infant care apparatus of claim 21, wherein movement of the support device in the horizontal and vertical directions is coordinated to obtain at least one motion profile.

23. The infant care apparatus of claim 21, wherein the support device is moved in the vertical direction a maximum of about 1.5 inches and the support device is moved in the horizontal direction a maximum of about 3.0 inches.

24. The infant care apparatus of claim 21, wherein movement in the vertical direction has a frequency range of between about 10 and 40 cycles per minute and movement in the horizontal direction has a frequency range of between about 10 and 40 cycles per minute.

25. A variable motion infant seat comprising:

a vertical reciprocating assembly for providing vertical motion and comprising a first motor;

a horizontal reciprocating assembly coupled to the vertical reciprocating assembly, the horizontal reciprocating assembly for providing horizontal motion and comprising a second motor;

at least one encoder configured for determining at least one of a rotational speed and a number of revolutions of a shaft of at least one of the first motor and the second motor and

a support device coupled to at least one of the vertical reciprocating assembly and the horizontal reciprocating assembly,

wherein the first motor and second motor are run at a substantially constant speed, thereby causing the vertical reciprocating assembly and horizontal reciprocating assembly to move the support device in at least one motion profile.

26. The variable motion infant seat of claim 25, further comprising a first encoder associated with the first motor and a second encoder associated with the second motor.

27. The variable motion infant seat of claim 26, wherein the first encoder and the second encoder each include no more than one slot.

28. The variable motion infant seat of claim 25, wherein the horizontal reciprocating assembly comprises:

a slide crank assembly comprising a gearing assembly coupled to a drive shaft of the first motor and a crank member coupled to the gearing assembly; and

a sliding stage coupled to the crank member,

wherein operation of the first motor causes rotation of the slide crank assembly, thereby imparting reciprocating horizontal motion to the sliding stage.

29. The variable motion infant seat of claim 25, wherein the vertical reciprocating assembly comprises:

a worm gear assembly coupled to the output of a drive shaft of the second motor; and

a vertical yoke having a first end coupled to an output shaft of the worm gear assembly,

wherein operation of the second motor causes rotation of the vertical yoke, thereby imparting reciprocating vertical motion to the support device.

30. The variable motion infant seat of claim 29, wherein the vertical reciprocating assembly further comprises a dual scissor mechanism coupled to a second end of the vertical yoke configured to support the support device.

31. The variable motion infant seat of claim 25, further comprising a control system electrically coupled to at least one of a vertical limit switch, a horizontal limit switch, and at least one encoder.

32. The variable motion infant seat of claim 31, wherein the first motor and the second motor are controlled by the control system to run at the substantially constant speed based on positional information from at least one of the vertical limit switch, the horizontal limit switch, and the at least one encoder.

33. The variable motion infant seat of claim 31, wherein the horizontal limit switch provides information to the control system regarding the initial position of the horizontal reciprocating assembly.

34. The variable motion infant seat of claim 31, wherein the vertical limit switch provides information to the control system regarding the initial position of the vertical reciprocating assembly.

35. The variable motion infant seat of claim 25, wherein the at least one motion profile comprises movement of the support device in a horizontal direction and a vertical direction relative to the base.

36. The variable motion infant seat of claim 25, wherein the at least one motion profile includes sinusoidal movement of the support device.

37. The variable motion infant seat of claim 36, wherein the sinusoidal movement has a smooth acceleration and deceleration such that extremes of the sinusoidal movement slow to a stop before reversing.

38. The variable motion infant seat of claim 25, wherein the support device comprises:

a seat support tube coupled to the drive mechanism;

a seating portion coupled to a first end and a second end of the seat support tube; and

a toy bar having a first end coupled to the second end of the seat support tube and a second end extending over the seating portion.

39. The variable motion infant seat of claim 25, wherein the first motor and second motor are each run in one direction to achieve the at least one motion profile.

40. A method for providing variable motion to a support portion of an infant seat comprising:

providing a first motor having a first encoder coupled to a drive shaft thereof;

providing a second motor having a second encoder coupled to a drive shaft thereof;

operationally coupling a support device to the first motor and the second motor;

determining positional information of the support portion using the first encoder, the second encoder, a vertical limit switch, and a horizontal limit switch; and

operating the first motor and the second motor at a substantially constant speed to move the support device in at least one motion profile based at least in part on positional information from the vertical limit switch, the horizontal limit switch, the first encoder, and the second encoder.

41. The method of claim 40, wherein the first encoder and the second encoder each include no more than one slot.

42. The method of claim 40, wherein the horizontal limit switch provides information regarding the initial position of the horizontal reciprocating assembly.

43. The method of claim 40, wherein the vertical limit switch provides information regarding the initial position of the vertical reciprocating assembly.

44. The method of claim 40, wherein the at least one motion profile comprises movement of the support device in a horizontal direction and a vertical direction relative to the base.

45. The method of claim 40, wherein the at least one motion profile comprises sinusoidal movement.

46. The method of claim 42, wherein the sinusoidal movement has a smooth acceleration and deceleration such that extremes of the sinusoidal movement slow to a stop before reversing.

47. The method of claim 43, wherein the first motor and the second motor are operated to move the support device in a plurality of motion profiles.
