(54) Title: BROADCAST SIGNAL TRANSMITTING APPARATUS, BROADCAST SIGNAL RECEIVING APPARATUS, BROADCAST SIGNAL TRANSMITTING METHOD, AND BROADCAST SIGNAL RECEIVING METHOD

(57) **Abrégé/Abstract:**

The present invention provides a method of transmitting broadcast signals. The method includes, formatting, by an input formatting block, input streams into plural PLPs(Physical Layer Pipes); encoding, by an encoder, data in the plural PLPs; time interleaving, by a time interleaver, the encoded data in the plural PLPs, wherein the time interleaving includes: cell interleaving, by a cell interleaver, the encoded data by permuting cells in a FEC(Forward Error Correction) block in the plural PLPs; frame mapping, by a framer, the time interleaved data onto at least one signal frame; and waveform modulating, by a waveform block, the mapped data in the at least one signal frame and transmitting, by the waveform block, broadcast signals having the modulated data.

【ABSTRACT】

The present invention provides a method of transmitting broadcast signals. The method includes, formatting, by an input formatting block, input streams into plural PLPs(Physical Layer Pipes); encoding, by an encoder, data in the plural PLPs; time interleaving, by a time interleaver, the encoded data in the plural PLPs, wherein the time interleaving includes: cell interleaving, by a cell interleaver, the encoded data by permuting cells in a FEC(Forward Error Correction) block in the plural PLPs; frame mapping, by a framer, the time interleaved data onto at least one signal frame; and waveform modulating, by a waveform block, the mapped data in the at least one signal frame and transmitting, by the waveform block, broadcast signals having the modulated data.

【DESCRIPTION】**【Invention Title】**

BROADCAST SIGNAL TRANSMITTING APPARATUS, BROADCAST SIGNAL RECEIVING APPARATUS,
BROADCAST SIGNAL TRANSMITTING METHOD, AND BROADCAST SIGNAL RECEIVING METHOD

【Technical Field】

The present invention relates to an apparatus for transmitting broadcast signals, an apparatus for receiving broadcast signals and methods for transmitting and receiving broadcast signals.

【Background Art】

As analog broadcast signal transmission comes to an end, various technologies for transmitting/receiving digital broadcast signals are being developed. A digital broadcast signal may include a larger amount of video/audio data than an analog broadcast signal and further include various types of additional data in addition to the video/audio data.

That is, a digital broadcast system can provide HD (high definition) images, multi-channel audio and various additional services. However, data transmission efficiency for transmission of large amounts of data, robustness of transmission/reception networks and network flexibility in consideration of mobile reception equipment need to be improved for digital broadcast.

【Disclosure】**【Technical Problem】**

An object of the present invention is to provide an apparatus and method for transmitting broadcast signals to multiplex data of a broadcast transmission/reception system providing two or more different broadcast services in a time domain and transmit the multiplexed data through the same RF signal bandwidth and an apparatus and method for receiving broadcast signals corresponding thereto.

Another object of the present invention is to provide an apparatus for transmitting broadcast signals, an apparatus for receiving broadcast signals and methods for transmitting and receiving broadcast signals to classify data corresponding to services by components, transmit data corresponding to each component as a data pipe, receive and process the data

Still another object of the present invention is to provide an apparatus for transmitting broadcast signals, an apparatus for receiving broadcast signals and methods for transmitting and receiving broadcast signals to signal signaling information necessary to provide broadcast signals.

【Technical Solution】

To achieve the object and other advantages and in accordance with the purpose of the invention, as

embodied and broadly described herein, the present invention provides a method of transmitting broadcast signals. The method of transmitting broadcast signals includes formatting, by an input formatting block, input streams into plural PLPs(Physical Layer Pipes); encoding, by an encoder, data in the plural PLPs; time interleaving, by a time interleaver, the encoded data in the plural PLPs, wherein the time interleaving includes: cell interleaving, by a cell interleaver, the encoded data by permuting cells in a FEC(Forward Error Correction) block in the plural PLPs; frame mapping, by a framer, the time interleaved data onto at least one signal frame; and waveform modulating, by a waveform block, the mapped data in the at least one signal frame and transmitting, by the waveform block, broadcast signals having the modulated data.

Preferably, the cell interleaving further includes: writing the cells in the FEC block into a memory linearly, and reading the cells from the memory randomly by using a permutation sequence.

Preferably, the permutation sequence is different for each FEC block in the plural PLPs.

Preferably, the permutation sequences for each FEC block are determined by shifting a basic permutation sequence differently.

Preferably, the permutation sequence is generated by adding a shifting value to the basic permutation sequence, and by applying modulo operation with a number of cells in the FEC block, wherein the shifting value is different for each FEC block in the plural PLPs.

Preferably, the basic permutation sequence is a pseudo random sequence.

Preferably, the time interleaving further includes: block interleaving, by a block interleaver, at least one TI (Time Interleaving) block including at least one of the FEC blocks, and convolutional interleaving, by a convolutional delay line block, the block interleaved at least one TI block.

Preferably, the encoding data in the plural PLPs further includes: FEC encoding, by a FEC encoder, the data in the plural PLPs, bit interleaving, by a bit interleaver, the FEC encoded data in the plural PLPs, and constellation mapping, by a mapper, the bit interleaved data to the FEC block by mapping onto constellations.

In other aspect, the present invention provides a method of receiving broadcast signals. The method of receiving broadcast signals includes receiving, by a waveform block, broadcast signals having at least one signal frame and demodulating, by the waveform block, data in the at least one signal frame; frame parsing, by a frame parser, the demodulated data in the at least one signal frame by demapping plural PLPs(Physical Layer Pipes); time deinterleaving, by a time deinterleaver, data in the plural PLPs, wherein the time deinterleaving includes: cell deinterleaving, by a cell deinterleaver, the data in the plural PLPs by permuting cells in a FEC(Forward Error Correction) block in the plural PLPs;

decoding, by a decoder, the time deinterleaved data in the plural PLPs; and output processing, by an output processing block, the decoded data in the plural PLPs to output output streams.

Preferably, the cell deinterleaving further includes: writing the cells in the FEC block into a memory randomly by using a permutation sequence, and reading the cells from the memory linearly.

Preferably, the permutation sequence is different for each FEC block in the plural PLPs.

Preferably, the permutation sequences for each FEC block are determined by shifting a basic permutation sequence differently.

Preferably, the permutation sequence is generated by adding a shifting value to the basic permutation sequence, and by applying modulo operation with a number of cells in the FEC block, wherein the shifting value is different for each FEC block in the plural PLPs.

Preferably, the basic permutation sequence is a pseudo random sequence.

Preferably, the time deinterleaving further includes: convolutional deinterleaving, by a convolutional delay line block, data in the plural PLPs, and block deinterleaving, by a block deinterleaver, the convolutional deinterleaved data including at least one of the FEC blocks.

Preferably, the decoding the time deinterleaved data in the plural PLPs further includes: constellation demapping, by a demapper, the time deinterleaved data from constellations, bit deinterleaving, by a bit deinterleaver, the demapped data in the plural PLPs, and FEC decoding, by a FEC decoder, the bit deinterleaved data in the plural PLPs.

In another aspect, the present invention provides an apparatus for transmitting broadcast signals. The apparatus for transmitting broadcast signals includes an input formatting block that formats input streams into plural PLPs(Physical Layer Pipes); an encoder that encodes data in the plural PLPs; a time interleaver that time interleaves the encoded data in the plural PLPs, wherein the time interleaver includes: a cell interleaver that cell interleaves the encoded data by permuting cells in a FEC(Forward Error Correction) block in the plural PLPs; a framer that maps the time interleaved data onto at least one signal frame; and a waveform block that waveform modulates the mapped data in the at least one signal frame and that transmits broadcast signals having the modulated data.

Preferably, the cell interleaver writes the cells in the FEC block into a memory linearly, and wherein the cell interleaver reads the cells from the memory randomly by using a permutation sequence.

Preferably, the permutation sequence is different for each FEC block in the plural PLPs.

Preferably, the permutation sequences for each FEC block are determined by shifting a basic permutation sequence differently.

Preferably, the permutation sequence is generated by adding a shifting value to the basic permutation

sequence, and by applying modulo operation with a number of cells in the FEC block, wherein the shifting value is different for each FEC block in the plural PLPs.

Preferably, the basic permutation sequence is a pseudo random sequence.

Preferably, the time interleaver further includes: a block interleaver that block interleaves at least one TI (Time Interleaving) block including at least one of the FEC blocks, and a convolutional delay line block that convolutional interleaves the block interleaved at least one TI block.

Preferably, the encoder further includes: a FEC encoder that FEC encodes the data in the plural PLPs, a bit interleaver that bit interleaves the FEC encoded data in the plural PLPs, and a constellation mapper that maps the bit interleaved data to the FEC block by mapping onto constellations.

In another aspect, the present invention provides an apparatus for receiving broadcast signals. The apparatus for receiving broadcast signals includes a waveform block that receives broadcast signals having at least one signal frame and demodulates data in the at least one signal frame; a frame parser that parses the demodulated data in the at least one signal frame by demapping plural PLPs(Physical Layer Pipes); a time deinterleaver that time deinterleaves data in the plural PLPs, wherein the time deinterleaver includes: a cell deinterleaver that cell deinterleaves the data in the plural PLPs by permuting cells in a FEC(Forward Error Correction) block in the plural PLPs; a decoder that decodes the time deinterleaved data in the plural PLPs; and an output processing block that output processes the decoded data in the plural PLPs to output output streams.

Preferably, the cell deinterleaver writes the cells in the FEC block into a memory randomly by using a permutation sequence, and wherein the cell deinterleaver reads the cells from the memory linearly.

Preferably, the permutation sequence is different for each FEC block in the plural PLPs.

Preferably, the permutation sequences for each FEC block are determined by shifting a basic permutation sequence differently.

Preferably, the permutation sequence is generated by adding a shifting value to the basic permutation sequence, and by applying modulo operation with a number of cells in the FEC block, wherein the shifting value is different for each FEC block in the plural PLPs.

Preferably, the basic permutation sequence is a pseudo random sequence.

Preferably, the time deinterleaver further includes: a convolutional delay line block that convolutional deinterleaves data in the plural PLPs, and a block deinterleaver that block deinterleaves the convolutional deinterleaved data including at least one of the FEC blocks.

Preferably, the decoder further includes: a constellation demapper that demaps the time deinterleaved data from constellations, a bit deinterleaver that bit deinterleaves the demapped data in the plural PLPs,

and a FEC decoder that FEC decodes the bit deinterleaved data in the plural PLPs. According to another aspect of the present disclosure, there is provided a method of receiving broadcast signals, the method including: receiving broadcast signals having at least one signal frame; demodulating data in the at least one signal frame; frame parsing the demodulated data in the at least one signal frame by demapping plural Physical Layer Pipes, PLPs; cell deinterleaving cells of the plural PLPs arranged in Forward Error Correction, FEC, blocks, wherein at least one FEC block is included in a Time Interleaving, TI, block, wherein the cell deinterleaving includes writing cells in a FEC block into a memory randomly by using a permutation sequence, reading the cells from the memory linearly, wherein the permutation sequence varies each FEC block with a TI block by shifting a basic permutation sequence based on a shift value respectively; decoding data in the cell deinterleaved cells; and output formatting the decoded data to output streams.

There is also provided an apparatus for receiving broadcast signals, the apparatus including: a receiver to receive broadcast signals having at least one signal frame; a demodulator to demodulate data in the at least one signal frame; a frame parser to parse the demodulated data in the at least one signal frame by demapping plural Physical Layer Pipes, PLPs; a cell deinterleaver to cell deinterleave cells of the plural PLPs arranged in Forward Error Correction, FEC, blocks, wherein at least one FEC block is included in a Time Interleaving, TI, block, wherein the cell deinterleaver performs: writing cells in a FEC block into a memory randomly by using a permutation sequence, reading the cells from the memory linearly, wherein the permutation sequence varies each FEC block with a TI block by shifting a basic permutation sequence based on a shift value respectively; a decoder to decode data in the cell deinterleaved cells; and an output formatter to output the decoded data to output streams.

【Advantageous Effects】

The present invention can process data according to service characteristics to control QoS (Quality of Services) for each service or service component, thereby providing various broadcast services.

The present invention can achieve transmission flexibility by transmitting various broadcast services through the same RF signal bandwidth.

The present invention can improve data transmission efficiency and increase robustness of transmission/reception of broadcast signals using a MIMO system. According to the present invention, it is possible to provide broadcast signal transmission and reception methods and apparatus capable of receiving digital broadcast signals without error even with mobile reception equipment or in an indoor environment.

【Description of Drawings】

The accompanying drawings, which are included to provide a further understanding of the invention and are incorporated in and constitute a part of this application, illustrate embodiment(s) of the invention and together with the description serve to explain the principle of the invention. In the drawings:

FIG. 1 illustrates a structure of an apparatus for transmitting broadcast signals for future broadcast services according to an embodiment of the present invention.

FIG. 2 illustrates an input formatting block according to one embodiment of the present invention.

FIG. 3 illustrates an input formatting block according to another embodiment of the present invention.

FIG. 4 illustrates an input formatting block according to another embodiment of the present invention.

FIG. 5 illustrates a BICM block according to an embodiment of the present invention.

FIG. 6 illustrates a BICM block according to another embodiment of the present invention.

FIG. 7 illustrates a frame building block according to one embodiment of the present invention.

FIG. 8 illustrates an OFDM generation block according to an embodiment of the present invention.

FIG. 9 illustrates a structure of an apparatus for receiving broadcast signals for future broadcast services according to an embodiment of the present invention.

FIG. 10 illustrates a frame structure according to an embodiment of the present invention.

FIG. 11 illustrates a signaling hierarchy structure of the frame according to an embodiment of the present invention.

according to an embodiment of the present invention.

FIG. 37 is a view illustrating operation of the periodic-random I/Q interleaving technology in the case of 4D-SSD when N is 24, according to an embodiment of the present invention.

FIG. 38 is a detailed block diagram of a demapping & decoding module according to another embodiment of the present invention.

FIG. 39 is a view illustrating a periodic-random I/Q deinterleaving technology according to an embodiment of the present invention.

FIG. 40 illustrates a part of a broadcast signal transmitter for next-generation broadcast service according to another embodiment of the present invention.

FIG. 41 is a view illustrating a basic switch structure according to an embodiment of the present invention.

FIG. 42 is a view mathematically expressing linear writing & random reading operation of the cell interleaver according to another embodiment of the present invention.

FIG. 43 is a view mathematically expressing a permutation sequence generating method of the cell interleaver according to another embodiment of the present invention cell interleaver.

FIG. 44 illustrates a part of a broadcast signal receiver for next-generation broadcast service including a cell deinterleaver according to another embodiment of the present invention.

FIG. 45 is a view illustrating a broadcast signal transmitting method according to an embodiment of the present invention.

FIG. 46 is a view illustrating a broadcast signal transmitter according to an embodiment of the present invention.

【Best Mode】

Reference will now be made in detail to the preferred embodiments of the present invention, examples of which are illustrated in the accompanying drawings. The detailed description, which will be given below with reference to the accompanying drawings, is intended to explain exemplary embodiments of the present invention, rather than to show the only embodiments that can be implemented according to the present invention. The following detailed description includes specific details in order to provide a thorough understanding of the present invention. However, it will be apparent to those skilled in the art that the present invention may be practiced without such specific details.

Although most terms used in the present invention have been selected from general ones widely used in the art, some terms have been arbitrarily selected by the applicant and their meanings are explained in detail in the following description as needed. Thus, the present invention should be understood based

upon the intended meanings of the terms rather than their simple names or meanings.

The present invention provides apparatuses and methods for transmitting and receiving broadcast signals for future broadcast services. Future broadcast services according to an embodiment of the present invention include a terrestrial broadcast service, a mobile broadcast service, a UHDTV service, etc. The present invention may process broadcast signals for the future broadcast services through non-MIMO (Multiple Input Multiple Output) or MIMO according to one embodiment. A non-MIMO scheme according to an embodiment of the present invention may include a MISO (Multiple Input Single Output) scheme, a SISO (Single Input Single Output) scheme, etc.

While MISO or MIMO uses two antennas in the following for convenience of description, the present invention is applicable to systems using two or more antennas.

The present invention may defines three physical layer (PL) profiles (base, handheld and advanced profiles), each optimized to minimize receiver complexity while attaining the performance required for a particular use case. The physical layer (PHY) profiles are subsets of all configurations that a corresponding receiver should implement.

The three PHY profiles share most of the functional blocks but differ slightly in specific blocks and/or parameters. Additional PHY profiles can be defined in the future. For the system evolution, future profiles can also be multiplexed with the existing profiles in a single RF channel through a future extension frame (FEF). The details of each PHY profile are described below.

1. Base profile

The base profile represents a main use case for fixed receiving devices that are usually connected to a roof-top antenna. The base profile also includes portable devices that could be transported to a place but belong to a relatively stationary reception category. Use of the base profile could be extended to handheld devices or even vehicular by some improved implementations, but those use cases are not expected for the base profile receiver operation.

Target SNR range of reception is from approximately 10 to 20dB, which includes the 15dB SNR reception capability of the existing broadcast system (e.g. ATSC A/53). The receiver complexity and power consumption is not as critical as in the battery-operated handheld devices, which will use the handheld profile. Key system parameters for the base profile are listed in below table 1.

【Table 1】

LDPC codeword length	16K, 64K bits
Constellation size	4~10 bpcu (bits per channel use)
Time de-interleaving memory size	$\leq 2^{19}$ data cells
Pilot patterns	Pilot pattern for fixed reception
FFT size	16K, 32K points

2. Handheld profile

The handheld profile is designed for use in handheld and vehicular devices that operate with battery power. The devices can be moving with pedestrian or vehicle speed. The power consumption as well as the receiver complexity is very important for the implementation of the devices of the handheld profile. The target SNR range of the handheld profile is approximately 0 to 10dB, but can be configured to reach below 0dB when intended for deeper indoor reception.

In addition to low SNR capability, resilience to the Doppler Effect caused by receiver mobility is the most important performance attribute of the handheld profile. Key system parameters for the handheld profile are listed in the below table 2.

【Table 2】

LDPC codeword length	16K bits
Constellation size	2~8 bpcu
Time de-interleaving memory size	$\leq 2^{18}$ data cells
Pilot patterns	Pilot patterns for mobile and indoor reception
FFT size	8K, 16K points

3. Advanced profile

The advanced profile provides highest channel capacity at the cost of more implementation complexity. This profile requires using MIMO transmission and reception, and UHDTV service is a target use case for which this profile is specifically designed. The increased capacity can also be used to allow an increased number of services in a given bandwidth, e.g., multiple SDTV or HDTV services.

The target SNR range of the advanced profile is approximately 20 to 30dB. MIMO transmission may initially use existing elliptically-polarized transmission equipment, with extension to full-power cross-polarized transmission in the future. Key system parameters for the advanced profile are listed in below table 3.

【Table 3】

LDPC codeword length	16K, 64K bits
Constellation size	8~12 bpcu
Time de-interleaving memory size	$\leq 2^{29}$ data cells
Pilot patterns	Pilot pattern for fixed reception
FFT size	16K, 32K points

In this case, the base profile can be used as a profile for both the terrestrial broadcast service and the mobile broadcast service. That is, the base profile can be used to define a concept of a profile which includes the mobile profile. Also, the advanced profile can be divided advanced profile for a base profile with MIMO and advanced profile for a handheld profile with MIMO. Moreover, the three profiles can be changed according to intention of the designer.

The following terms and definitions may apply to the present invention. The following terms and definitions can be changed according to design.

auxiliary stream: sequence of cells carrying data of as yet undefined modulation and coding, which may be used for future extensions or as required by broadcasters or network operators

base data pipe: data pipe that carries service signaling data

baseband frame (or BBFRAME): set of K_{bch} bits which form the input to one FEC encoding process (BCH and LDPC encoding)

cell: modulation value that is carried by one carrier of the OFDM transmission

coded block: LDPC-encoded block of PLS1 data or one of the LDPC-encoded blocks of PLS2 data

data pipe: logical channel in the physical layer that carries service data or related metadata, which may carry one or multiple service(s) or service component(s).

data pipe unit: a basic unit for allocating data cells to a DP in a frame.

data symbol: OFDM symbol in a frame which is not a preamble symbol (the frame signaling symbol and frame edge symbol is included in the data symbol)

DP_ID: this 8-bit field identifies uniquely a DP within the system identified by the SYSTEM_ID

dummy cell: cell carrying a pseudo-random value used to fill the remaining capacity not used for PLS signaling, DPs or auxiliary streams

emergency alert channel: part of a frame that carries EAS information data

frame: physical layer time slot that starts with a preamble and ends with a frame edge symbol

frame repetition unit: a set of frames belonging to same or different physical layer profile including a FEF, which is repeated eight times in a super-frame

fast information channel: a logical channel in a frame that carries the mapping information between a service and the corresponding base DP

FECBLOCK: set of LDPC-encoded bits of a DP data

FFT size: nominal FFT size used for a particular mode, equal to the active symbol period T_s expressed in cycles of the elementary period T

frame signaling symbol: OFDM symbol with higher pilot density used at the start of a frame in certain combinations of FFT size, guard interval and scattered pilot pattern, which carries a part of the PLS data

frame edge symbol: OFDM symbol with higher pilot density used at the end of a frame in certain combinations of FFT size, guard interval and scattered pilot pattern

frame-group: the set of all the frames having the same PHY profile type in a super-frame.

future extension frame: physical layer time slot within the super-frame that could be used for future extension, which starts with a preamble

Futurecast UTB system: proposed physical layer broadcasting system, of which the input is one or more MPEG2-TS or IP or general stream(s) and of which the output is an RF signal

input stream: A stream of data for an ensemble of services delivered to the end users by the system.

normal data symbol: data symbol excluding the frame signaling symbol and the frame edge symbol

PHY profile: subset of all configurations that a corresponding receiver should implement

PLS: physical layer signaling data consisting of PLS1 and PLS2

PLS1: a first set of PLS data carried in the FSS symbols having a fixed size, coding and modulation, which carries basic information about the system as well as the parameters needed to decode the PLS2

NOTE: PLS1 data remains constant for the duration of a frame-group.

PLS2: a second set of PLS data transmitted in the FSS symbol, which carries more detailed PLS data about the system and the DPs

PLS2 dynamic data: PLS2 data that may dynamically change frame-by-frame

PLS2 static data: PLS2 data that remains static for the duration of a frame-group

preamble signaling data: signaling data carried by the preamble symbol and used to identify the basic mode of the system

preamble symbol: fixed-length pilot symbol that carries basic PLS data and is located in the beginning of a frame

NOTE: The preamble symbol is mainly used for fast initial band scan to detect the system signal, its timing, frequency offset, and FFT-size.

reserved for future use: not defined by the present document but may be defined in future

super-frame: set of eight frame repetition units

time interleaving block (TI block): set of cells within which time interleaving is carried out, corresponding

to one use of the time interleaver memory

TI group: unit over which dynamic capacity allocation for a particular DP is carried out, made up of an integer, dynamically varying number of XFECBLOCKs.

NOTE: The TI group may be mapped directly to one frame or may be mapped to multiple frames.

It may contain one or more TI blocks.

Type 1 DP: DP of a frame where all DPs are mapped into the frame in TDM fashion

Type 2 DP: DP of a frame where all DPs are mapped into the frame in FDM fashion

XFECBLOCK: set of N_{cells} cells carrying all the bits of one LDPC FECBLOCK

FIG. 1 illustrates a structure of an apparatus for transmitting broadcast signals for future broadcast services according to an embodiment of the present invention.

The apparatus for transmitting broadcast signals for future broadcast services according to an embodiment of the present invention can include an input formatting block 1000, a BICM (Bit interleaved coding & modulation) block 1010, a frame structure block 1020, an OFDM (Orthogonal Frequency Division Multiplexing) generation block 1030 and a signaling generation block 1040. A description will be given of the operation of each module of the apparatus for transmitting broadcast signals.

IP stream/packets and MPEG2-TS are the main input formats, other stream types are handled as General Streams. In addition to these data inputs, Management Information is input to control the scheduling and allocation of the corresponding bandwidth for each input stream. One or multiple TS stream(s), IP stream(s) and/or General Stream(s) inputs are simultaneously allowed.

The input formatting block 1000 can demultiplex each input stream into one or multiple data pipe(s), to each of which an independent coding and modulation is applied. The data pipe (DP) is the basic unit for robustness control, thereby affecting quality-of-service (QoS). One or multiple service(s) or service component(s) can be carried by a single DP. Details of operations of the input formatting block 1000 will be described later.

The data pipe is a logical channel in the physical layer that carries service data or related metadata, which may carry one or multiple service(s) or service component(s).

Also, the data pipe unit: a basic unit for allocating data cells to a DP in a frame.

In the BICM block 1010, parity data is added for error correction and the encoded bit streams are mapped to complex-value constellation symbols. The symbols are interleaved across a specific interleaving depth that is used for the corresponding DP. For the advanced profile, MIMO encoding is performed in the BICM block 1010 and the additional data path is added at the output for MIMO transmission. Details of operations of the BICM block 1010 will be described later.

The Frame Building block 1020 can map the data cells of the input DPs into the OFDM symbols within a frame. After mapping, the frequency interleaving is used for frequency-domain diversity, especially to combat frequency-selective fading channels. Details of operations of the Frame Building block 1020 will be described later.

After inserting a preamble at the beginning of each frame, the OFDM Generation block 1030 can apply conventional OFDM modulation having a cyclic prefix as guard interval. For antenna space diversity, a distributed MISO scheme is applied across the transmitters. In addition, a Peak-to-Average Power Reduction (PAPR) scheme is performed in the time domain. For flexible network planning, this proposal provides a set of various FFT sizes, guard interval lengths and corresponding pilot patterns. Details of operations of the OFDM Generation block 1030 will be described later.

The Signaling Generation block 1040 can create physical layer signaling information used for the operation of each functional block. This signaling information is also transmitted so that the services of interest are properly recovered at the receiver side. Details of operations of the Signaling Generation block 1040 will be described later.

FIGS. 2, 3 and 4 illustrate the input formatting block 1000 according to embodiments of the present invention. A description will be given of each figure.

FIG. 2 illustrates an input formatting block according to one embodiment of the present invention. FIG. 2 shows an input formatting module when the input signal is a single input stream.

The input formatting block illustrated in FIG. 2 corresponds to an embodiment of the input formatting block 1000 described with reference to FIG. 1.

The input to the physical layer may be composed of one or multiple data streams. Each data stream is carried by one DP. The mode adaptation modules slice the incoming data stream into data fields of the baseband frame (BBF). The system supports three types of input data streams: MPEG2-TS, Internet protocol (IP) and Generic stream (GS). MPEG2-TS is characterized by fixed length (188 byte) packets with the first byte being a sync-byte (0x47). An IP stream is composed of variable length IP datagram packets, as signaled within IP packet headers. The system supports both IPv4 and IPv6 for the IP stream. GS may be composed of variable length packets or constant length packets, signaled within encapsulation packet headers.

(a) shows a mode adaptation block 2000 and a stream adaptation 2010 for signal DP and (b) shows a PLS generation block 2020 and a PLS scrambler 2030 for generating and processing PLS data. A description will be given of the operation of each block.

The Input Stream Splitter splits the input TS, IP, GS streams into multiple service or service component

(audio, video, etc.) streams. The mode adaptation module 2010 is comprised of a CRC Encoder, BB (baseband) Frame Slicer, and BB Frame Header Insertion block.

The CRC Encoder provides three kinds of CRC encoding for error detection at the user packet (UP) level, i.e., CRC-8, CRC-16, and CRC-32. The computed CRC bytes are appended after the UP. CRC-8 is used for TS stream and CRC-32 for IP stream. If the GS stream doesn't provide the CRC encoding, the proposed CRC encoding should be applied.

BB Frame Slicer maps the input into an internal logical-bit format. The first received bit is defined to be the MSB. The BB Frame Slicer allocates a number of input bits equal to the available data field capacity. To allocate a number of input bits equal to the BBF payload, the UP packet stream is sliced to fit the data field of BBF.

BB Frame Header Insertion block can insert fixed length BBF header of 2 bytes is inserted in front of the BB Frame. The BBF header is composed of STUFFI (1 bit), SYNCN (13 bits), and RFU (2 bits). In addition to the fixed 2-Byte BBF header, BBF can have an extension field (1 or 3 bytes) at the end of the 2-byte BBF header.

The stream adaptation 2010 is comprised of stuffing insertion block and BB scrambler.

The stuffing insertion block can insert stuffing field into a payload of a BB frame. If the input data to the stream adaptation is sufficient to fill a BB-Frame, STUFFI is set to '0' and the BBF has no stuffing field. Otherwise STUFFI is set to '1' and the stuffing field is inserted immediately after the BBF header. The stuffing field comprises two bytes of the stuffing field header and a variable size of stuffing data.

The BB scrambler scrambles complete BBF for energy dispersal. The scrambling sequence is synchronous with the BBF. The scrambling sequence is generated by the feed-back shift register.

The PLS generation block 2020 can generate physical layer signaling (PLS) data. The PLS provides the receiver with a means to access physical layer DPs. The PLS data consists of PLS1 data and PLS2 data.

The PLS1 data is a first set of PLS data carried in the FSS symbols in the frame having a fixed size, coding and modulation, which carries basic information about the system as well as the parameters needed to decode the PLS2 data. The PLS1 data provides basic transmission parameters including parameters required to enable the reception and decoding of the PLS2 data. Also, the PLS1 data remains constant for the duration of a frame-group.

The PLS2 data is a second set of PLS data transmitted in the FSS symbol, which carries more detailed PLS data about the system and the DPs. The PLS2 contains parameters that provide sufficient information for the receiver to decode the desired DP. The PLS2 signaling further consists of two types of parameters, PLS2 Static data (PLS2-STAT data) and PLS2 dynamic data (PLS2-DYN data). The PLS2 Static data is PLS2

data that remains static for the duration of a frame-group and the PLS2 dynamic data is PLS2 data that may dynamically change frame-by-frame.

Details of the PLS data will be described later.

The PLS scrambler 2030 can scramble the generated PLS data for energy dispersal.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions.

FIG. 3 illustrates an input formatting block according to another embodiment of the present invention.

The input formatting block illustrated in FIG. 3 corresponds to an embodiment of the input formatting block 1000 described with reference to FIG. 1.

FIG. 3 shows a mode adaptation block of the input formatting block when the input signal corresponds to multiple input streams.

The mode adaptation block of the input formatting block for processing the multiple input streams can independently process the multiple input streams.

Referring to FIG. 3, the mode adaptation block for respectively processing the multiple input streams can include an input stream splitter 3000, an input stream synchronizer 3010, a compensating delay block 3020, a null packet deletion block 3030, a head compression block 3040, a CRC encoder 3050, a BB frame slicer 3060 and a BB header insertion block 3070. Description will be given of each block of the mode adaptation block.

Operations of the CRC encoder 3050, BB frame slicer 3060 and BB header insertion block 3070 correspond to those of the CRC encoder, BB frame slicer and BB header insertion block described with reference to FIG. 2 and thus description thereof is omitted.

The input stream splitter 3000 can split the input TS, IP, GS streams into multiple service or service component (audio, video, etc.) streams.

The input stream synchronizer 3010 may be referred as ISSY. The ISSY can provide suitable means to guarantee Constant Bit Rate (CBR) and constant end-to-end transmission delay for any input data format. The ISSY is always used for the case of multiple DPs carrying TS, and optionally used for multiple DPs carrying GS streams.

The compensating delay block 3020 can delay the split TS packet stream following the insertion of ISSY information to allow a TS packet recombining mechanism without requiring additional memory in the receiver.

The null packet deletion block 3030, is used only for the TS input stream case. Some TS input streams or split TS streams may have a large number of null-packets present in order to accommodate VBR (variable bit-rate) services in a CBR TS stream. In this case, in order to avoid unnecessary transmission overhead,

null-packets can be identified and not transmitted. In the receiver, removed null-packets can be re-inserted in the exact place where they were originally by reference to a deleted null-packet (DNP) counter that is inserted in the transmission, thus guaranteeing constant bit-rate and avoiding the need for time-stamp (PCR) updating.

The head compression block 3040 can provide packet header compression to increase transmission efficiency for TS or IP input streams. Because the receiver can have a priori information on certain parts of the header, this known information can be deleted in the transmitter.

For Transport Stream, the receiver has a-priori information about the sync-byte configuration (0x47) and the packet length (188 Byte). If the input TS stream carries content that has only one PID, i.e., for only one service component (video, audio, etc.) or service sub-component (SVC base layer, SVC enhancement layer, MVC base view or MVC dependent views), TS packet header compression can be applied (optionally) to the Transport Stream. IP packet header compression is used optionally if the input stream is an IP stream.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions.

FIG. 4 illustrates an input formatting block according to another embodiment of the present invention.

The input formatting block illustrated in FIG. 4 corresponds to an embodiment of the input formatting block 1000 described with reference to FIG. 1.

FIG. 4 illustrates a stream adaptation block of the input formatting module when the input signal corresponds to multiple input streams.

Referring to FIG. 4, the mode adaptation block for respectively processing the multiple input streams can include a scheduler 4000, an 1-Frame delay block 4010, a stuffing insertion block 4020, an in-band signaling 4030, a BB Frame scrambler 4040, a PLS generation block 4050 and a PLS scrambler 4060. Description will be given of each block of the stream adaptation block.

Operations of the stuffing insertion block 4020, the BB Frame scrambler 4040, the PLS generation block 4050 and the PLS scrambler 4060 correspond to those of the stuffing insertion block, BB scrambler, PLS generation block and the PLS scrambler described with reference to FIG. 2 and thus description thereof is omitted.

The scheduler 4000 can determine the overall cell allocation across the entire frame from the amount of FECBLOCKs of each DP. Including the allocation for PLS, EAC and FIC, the scheduler generate the values of PLS2-DYN data, which is transmitted as in-band signaling or PLS cell in FSS of the frame. Details of FECBLOCK, EAC and FIC will be described later.

The 1-Frame delay block 4010 can delay the input data by one transmission frame such that scheduling

information about the next frame can be transmitted through the current frame for in-band signaling information to be inserted into the DPs.

The in-band signaling 4030 can insert un-delayed part of the PLS2 data into a DP of a frame.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions.

FIG. 5 illustrates a BICM block according to an embodiment of the present invention.

The BICM block illustrated in FIG. 5 corresponds to an embodiment of the BICM block 1010 described with reference to FIG. 1.

As described above, the apparatus for transmitting broadcast signals for future broadcast services according to an embodiment of the present invention can provide a terrestrial broadcast service, mobile broadcast service, UHDTV service, etc.

Since QoS (quality of service) depends on characteristics of a service provided by the apparatus for transmitting broadcast signals for future broadcast services according to an embodiment of the present invention, data corresponding to respective services needs to be processed through different schemes. Accordingly, the a BICM block according to an embodiment of the present invention can independently process DPs input thereto by independently applying SISO, MISO and MIMO schemes to the data pipes respectively corresponding to data paths. Consequently, the apparatus for transmitting broadcast signals for future broadcast services according to an embodiment of the present invention can control QoS for each service or service component transmitted through each DP.

(a) shows the BICM block shared by the base profile and the handheld profile and (b) shows the BICM block of the advanced profile.

The BICM block shared by the base profile and the handheld profile and the BICM block of the advanced profile can include plural processing blocks for processing each DP.

A description will be given of each processing block of the BICM block for the base profile and the handheld profile and the BICM block for the advanced profile.

A processing block 5000 of the BICM block for the base profile and the handheld profile can include a Data FEC encoder 5010, a bit interleaver 5020, a constellation mapper 5030, an SSD (Signal Space Diversity) encoding block 5040 and a time interleaver 5050.

The Data FEC encoder 5010 can perform the FEC encoding on the input BBF to generate FECBLOCK procedure using outer coding (BCH), and inner coding (LDPC). The outer coding (BCH) is optional coding method. Details of operations of the Data FEC encoder 5010 will be described later.

The bit interleaver 5020 can interleave outputs of the Data FEC encoder 5010 to achieve optimized performance with combination of the LDPC codes and modulation scheme while providing an efficiently

implementable structure. Details of operations of the bit interleaver 5020 will be described later.

The constellation mapper 5030 can modulate each cell word from the bit interleaver 5020 in the base and the handheld profiles, or cell word from the Cell-word demultiplexer 5010-1 in the advanced profile using either QPSK, QAM-16, non-uniform QAM (NUQ-64, NUQ-256, NUQ-1024) or non-uniform constellation (NUC-16, NUC-64, NUC-256, NUC-1024) to give a power-normalized constellation point, e_i . This constellation mapping is applied only for DPs. Observe that QAM-16 and NUQs are square shaped, while NUCs have arbitrary shape. When each constellation is rotated by any multiple of 90 degrees, the rotated constellation exactly overlaps with its original one. This "rotation-sense" symmetric property makes the capacities and the average powers of the real and imaginary components equal to each other. Both NUQs and NUCs are defined specifically for each code rate and the particular one used is signaled by the parameter DP_MOD filed in PLS2 data.

The SSD encoding block 5040 can precode cells in two (2D), three (3D), and four (4D) dimensions to increase the reception robustness under difficult fading conditions.

The time interleaver 5050 can operate at the DP level. The parameters of time interleaving (TI) may be set differently for each DP. Details of operations of the time interleaver 5050 will be described later.

A processing block 5000-1 of the BICM block for the advanced profile can include the Data FEC encoder, bit interleaver, constellation mapper, and time interleaver. However, the processing block 5000-1 is distinguished from the processing block 5000 further includes a cell-word demultiplexer 5010-1 and a MIMO encoding block 5020-1.

Also, the operations of the Data FEC encoder, bit interleaver, constellation mapper, and time interleaver in the processing block 5000-1 correspond to those of the Data FEC encoder 5010, bit interleaver 5020, constellation mapper 5030, and time interleaver 5050 described and thus description thereof is omitted. The cell-word demultiplexer 5010-1 is used for the DP of the advanced profile to divide the single cell-word stream into dual cell-word streams for MIMO processing. Details of operations of the cell-word demultiplexer 5010-1 will be described later.

The MIMO encoding block 5020-1 can process the output of the cell-word demultiplexer 5010-1 using MIMO encoding scheme. The MIMO encoding scheme was optimized for broadcasting signal transmission. The MIMO technology is a promising way to get a capacity increase but it depends on channel characteristics. Especially for broadcasting, the strong LOS component of the channel or a difference in the received signal power between two antennas caused by different signal propagation characteristics makes it difficult to get capacity gain from MIMO. The proposed MIMO encoding scheme overcomes this problem using a rotation-based pre-coding and phase randomization of one of the

MIMO output signals.

MIMO encoding is intended for a 2x2 MIMO system requiring at least two antennas at both the transmitter and the receiver. Two MIMO encoding modes are defined in this proposal; full-rate spatial multiplexing (FR-SM) and full-rate full-diversity spatial multiplexing (FRFD-SM). The FR-SM encoding provides capacity increase with relatively small complexity increase at the receiver side while the FRFD-SM encoding provides capacity increase and additional diversity gain with a great complexity increase at the receiver side. The proposed MIMO encoding scheme has no restriction on the antenna polarity configuration.

MIMO processing is required for the advanced profile frame, which means all DPs in the advanced profile frame are processed by the MIMO encoder. MIMO processing is applied at DP level. Pairs of the Constellation Mapper outputs NUQ ($e_{1,i}$ and $e_{2,i}$) are fed to the input of the MIMO Encoder. Paired MIMO Encoder output ($g_{1,i}$ and $g_{2,i}$) is transmitted by the same carrier k and OFDM symbol l of their respective TX antennas.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions.

FIG. 6 illustrates a BICM block according to another embodiment of the present invention.

The BICM block illustrated in FIG. 6 corresponds to an embodiment of the BICM block 1010 described with reference to FIG. 1.

FIG. 6 illustrates a BICM block for protection of physical layer signaling (PLS), emergency alert channel (EAC) and fast information channel (FIC). EAC is a part of a frame that carries EAS information data and FIC is a logical channel in a frame that carries the mapping information between a service and the corresponding base DP. Details of the EAC and FIC will be described later.

Referring to FIG. 6, the BICM block for protection of PLS, EAC and FIC can include a PLS FEC encoder 6000, a bit interleaver 6010, and a constellation mapper 6020.

Also, the PLS FEC encoder 6000 can include a scrambler, BCH encoding/zero insertion block, LDPC encoding block and LDPC parity puncturing block. Description will be given of each block of the BICM block.

The PLS FEC encoder 6000 can encode the scrambled PLS 1/2 data, EAC and FIC section.

The scrambler can scramble PLS1 data and PLS2 data before BCH encoding and shortened and punctured LDPC encoding.

The BCH encoding/zero insertion block can perform outer encoding on the scrambled PLS 1/2 data using the shortened BCH code for PLS protection and insert zero bits after the BCH encoding. For PLS1 data only, the output bits of the zero insertion may be permuted before LDPC encoding.

The LDPC encoding block can encode the output of the BCH encoding/zero insertion block using LDPC code. To generate a complete coded block, C_{ldpc} , parity bits, P_{ldpc} are encoded systematically from each zero-inserted PLS information block, I_{ldpc} and appended after it.

【Math Figure 1】

$$C_{ldpc} = [I_{ldpc} \ P_{ldpc}] = [i_0, i_1, \dots, i_{K_{ldpc}-1}, p_0, p_1, \dots, p_{N_{ldpc}-K_{ldpc}-1}]$$

The LDPC code parameters for PLS1 and PLS2 are as following table 4.

【Table 4】

Signaling Type	K_{sig}	K_{bch}	N_{bch_parity}	K_{ldpc} (= N_{bch})	N_{ldpc}	N_{ldpc_parity}	code rate	Q_{ldpc}
PLS1	342	1020	60	1080	4320	3240	1/4	36
PLS2	<1021							
	>1020	2100		2160	7200	5040	3/10	56

The LDPC parity puncturing block can perform puncturing on the PLS1 data and PLS 2 data.

When shortening is applied to the PLS1 data protection, some LDPC parity bits are punctured after LDPC encoding. Also, for the PLS2 data protection, the LDPC parity bits of PLS2 are punctured after LDPC encoding. These punctured bits are not transmitted.

The bit interleaver 6010 can interleave the each shortened and punctured PLS1 data and PLS2 data.

The constellation mapper 6020 can map the bit interleaveved PLS1 data and PLS2 data onto constellations.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions.

FIG. 7 illustrates a frame building block according to one embodiment of the present invention.

The frame building block illustrated in FIG. 7 corresponds to an embodiment of the frame building block 1020 described with reference to FIG. 1.

Referring to FIG. 7, the frame building block can include a delay compensation block 7000, a cell mapper 7010 and a frequency interleaver 7020. Description will be given of each block of the frame building block.

The delay compensation block 7000 can adjust the timing between the data pipes and the corresponding PLS data to ensure that they are co-timed at the transmitter end. The PLS data is delayed by the same amount as data pipes are by addressing the delays of data pipes caused by the Input Formatting block and BICM block. The delay of the BICM block is mainly due to the time interleaver. In-band signaling data carries information of the next TI group so that they are carried one frame ahead of the DPs to be signaled. The Delay Compensating block delays in-band signaling data accordingly.

The cell mapper 7010 can map PLS, EAC, FIC, DPs, auxiliary streams and dummy cells into the active

carriers of the OFDM symbols in the frame. The basic function of the cell mapper 7010 is to map data cells produced by the TIs for each of the DPs, PLS cells, and EAC/FIC cells, if any, into arrays of active OFDM cells corresponding to each of the OFDM symbols within a frame. Service signaling data (such as PSI(program specific information)/SI) can be separately gathered and sent by a data pipe. The Cell Mapper operates according to the dynamic information produced by the scheduler and the configuration of the frame structure. Details of the frame will be described later.

The frequency interleaver 7020 can randomly interleave data cells received from the cell mapper 7010 to provide frequency diversity. Also, the frequency interleaver 7020 can operate on every OFDM symbol pair comprised of two sequential OFDM symbols using a different interleaving-seed order to get maximum interleaving gain in a single frame.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions.

FIG. 8 illustrates an OFDM generation block according to an embodiment of the present invention.

The OFDM generation block illustrated in FIG. 8 corresponds to an embodiment of the OFDM generation block 1030 described with reference to FIG. 1.

The OFDM generation block modulates the OFDM carriers by the cells produced by the Frame Building block, inserts the pilots, and produces the time domain signal for transmission. Also, this block subsequently inserts guard intervals, and applies PAPR (Peak-to-Average Power Ratio) reduction processing to produce the final RF signal.

Referring to FIG. 8, the frame building block can include a pilot and reserved tone insertion block 8000, a 2D-eSFN encoding block 8010, an IFFT (Inverse Fast Fourier Transform) block 8020, a PAPR reduction block 8030, a guard interval insertion block 8040, a preamble insertion block 8050, other system insertion block 8060 and a DAC block 8070. Description will be given of each block of the frame building block.

The pilot and reserved tone insertion block 8000 can insert pilots and the reserved tone.

Various cells within the OFDM symbol are modulated with reference information, known as pilots, which have transmitted values known a priori in the receiver. The information of pilot cells is made up of scattered pilots, continual pilots, edge pilots, FSS (frame signaling symbol) pilots and FES (frame edge symbol) pilots. Each pilot is transmitted at a particular boosted power level according to pilot type and pilot pattern. The value of the pilot information is derived from a reference sequence, which is a series of values, one for each transmitted carrier on any given symbol. The pilots can be used for frame synchronization, frequency synchronization, time synchronization, channel estimation, and transmission mode identification, and also can be used to follow the phase noise.

Reference information, taken from the reference sequence, is transmitted in scattered pilot cells in every

symbol except the preamble, FSS and FES of the frame. Continual pilots are inserted in every symbol of the frame. The number and location of continual pilots depends on both the FFT size and the scattered pilot pattern. The edge carriers are edge pilots in every symbol except for the preamble symbol. They are inserted in order to allow frequency interpolation up to the edge of the spectrum. FSS pilots are inserted in FSS(s) and FES pilots are inserted in FES. They are inserted in order to allow time interpolation up to the edge of the frame.

The system according to an embodiment of the present invention supports the SFN network, where distributed MISO scheme is optionally used to support very robust transmission mode. The 2D-eSFN is a distributed MISO scheme that uses multiple TX antennas, each of which is located in the different transmitter site in the SFN network.

The 2D-eSFN encoding block 8010 can process a 2D-eSFN processing to distorts the phase of the signals transmitted from multiple transmitters, in order to create both time and frequency diversity in the SFN configuration. Hence, burst errors due to low flat fading or deep-fading for a long time can be mitigated. The IFFT block 8020 can modulate the output from the 2D-eSFN encoding block 8010 using OFDM modulation scheme. Any cell in the data symbols which has not been designated as a pilot (or as a reserved tone) carries one of the data cells from the frequency interleaver. The cells are mapped to OFDM carriers.

The PAPR reduction block 8030 can perform a PAPR reduction on input signal using various PAPR reduction algorithm in the time domain.

The guard interval insertion block 8040 can insert guard intervals and the preamble insertion block 8050 can insert preamble in front of the signal. Details of a structure of the preamble will be described later. The other system insertion block 8060 can multiplex signals of a plurality of broadcast transmission/reception systems in the time domain such that data of two or more different broadcast transmission/reception systems providing broadcast services can be simultaneously transmitted in the same RF signal bandwidth. In this case, the two or more different broadcast transmission/reception systems refer to systems providing different broadcast services. The different broadcast services may refer to a terrestrial broadcast service, mobile broadcast service, etc. Data related to respective broadcast services can be transmitted through different frames.

The DAC block 8070 can convert an input digital signal into an analog signal and output the analog signal. The signal output from the DAC block 7800 can be transmitted through multiple output antennas according to the physical layer profiles. A Tx antenna according to an embodiment of the present invention can have vertical or horizontal polarity.

The above-described blocks may be omitted or replaced by blocks having similar or identical functions according to design.

FIG. 9 illustrates a structure of an apparatus for receiving broadcast signals for future broadcast services according to an embodiment of the present invention.

The apparatus for receiving broadcast signals for future broadcast services according to an embodiment of the present invention can correspond to the apparatus for transmitting broadcast signals for future broadcast services, described with reference to FIG. 1.

The apparatus for receiving broadcast signals for future broadcast services according to an embodiment of the present invention can include a synchronization & demodulation module 9000, a frame parsing module 9010, a demapping & decoding module 9020, an output processor 9030 and a signaling decoding module 9040. A description will be given of operation of each module of the apparatus for receiving broadcast signals.

The synchronization & demodulation module 9000 can receive input signals through m Rx antennas, perform signal detection and synchronization with respect to a system corresponding to the apparatus for receiving broadcast signals and carry out demodulation corresponding to a reverse procedure of the procedure performed by the apparatus for transmitting broadcast signals.

The frame parsing module 9100 can parse input signal frames and extract data through which a service selected by a user is transmitted. If the apparatus for transmitting broadcast signals performs interleaving, the frame parsing module 9100 can carry out deinterleaving corresponding to a reverse procedure of interleaving. In this case, the positions of a signal and data that need to be extracted can be obtained by decoding data output from the signaling decoding module 9400 to restore scheduling information generated by the apparatus for transmitting broadcast signals.

The demapping & decoding module 9200 can convert the input signals into bit domain data and then deinterleave the same as necessary. The demapping & decoding module 9200 can perform demapping for mapping applied for transmission efficiency and correct an error generated on a transmission channel through decoding. In this case, the demapping & decoding module 9200 can obtain transmission parameters necessary for demapping and decoding by decoding the data output from the signaling decoding module 9400.

The output processor 9300 can perform reverse procedures of various compression/signal processing procedures which are applied by the apparatus for transmitting broadcast signals to improve transmission efficiency. In this case, the output processor 9300 can acquire necessary control information from data output from the signaling decoding module 9400. The output of the output

processor 8300 corresponds to a signal input to the apparatus for transmitting broadcast signals and may be MPEG-TSs, IP streams (v4 or v6) and generic streams.

The signaling decoding module 9400 can obtain PLS information from the signal demodulated by the synchronization & demodulation module 9000. As described above, the frame parsing module 9100, demapping & decoding module 9200 and output processor 9300 can execute functions thereof using the data output from the signaling decoding module 9400.

FIG. 10 illustrates a frame structure according to an embodiment of the present invention.

FIG. 10 shows an example configuration of the frame types and FRUs in a super-frame. (a) shows a super frame according to an embodiment of the present invention, (b) shows FRU (Frame Repetition Unit) according to an embodiment of the present invention, (c) shows frames of variable PHY profiles in the FRU and (d) shows a structure of a frame.

A super-frame may be composed of eight FRUs. The FRU is a basic multiplexing unit for TDM of the frames, and is repeated eight times in a super-frame.

Each frame in the FRU belongs to one of the PHY profiles, (base, handheld, advanced) or FEF. The maximum allowed number of the frames in the FRU is four and a given PHY profile can appear any number of times from zero times to four times in the FRU (e.g., base, base, handheld, advanced). PHY profile definitions can be extended using reserved values of the PHY_PROFILE in the preamble, if required. The FEF part is inserted at the end of the FRU, if included. When the FEF is included in the FRU, the minimum number of FEFs is 8 in a super-frame. It is not recommended that FEF parts be adjacent to each other.

One frame is further divided into a number of OFDM symbols and a preamble. As shown in (d), the frame comprises a preamble, one or more frame signaling symbols (FSS), normal data symbols and a frame edge symbol (FES).

The preamble is a special symbol that enables fast Futurecast UTB system signal detection and provides a set of basic transmission parameters for efficient transmission and reception of the signal. The detailed description of the preamble will be described later.

The main purpose of the FSS(s) is to carry the PLS data. For fast synchronization and channel estimation, and hence fast decoding of PLS data, the FSS has more dense pilot pattern than the normal data symbol. The FES has exactly the same pilots as the FSS, which enables frequency-only interpolation within the FES and temporal interpolation, without extrapolation, for symbols immediately preceding the FES.

FIG. 11 illustrates a signaling hierarchy structure of the frame according to an embodiment of the present invention.

FIG. 11 illustrates the signaling hierarchy structure, which is split into three main parts: the preamble signaling data 11000, the PLS1 data 11010 and the PLS2 data 11020. The purpose of the preamble, which is carried by the preamble symbol in every frame, is to indicate the transmission type and basic transmission parameters of that frame. The PLS1 enables the receiver to access and decode the PLS2 data, which contains the parameters to access the DP of interest. The PLS2 is carried in every frame and split into two main parts: PLS2-STAT data and PLS2-DYN data. The static and dynamic portion of PLS2 data is followed by padding, if necessary.

FIG. 12 illustrates preamble signaling data according to an embodiment of the present invention.

Preamble signaling data carries 21 bits of information that are needed to enable the receiver to access PLS data and trace DPs within the frame structure. Details of the preamble signaling data are as follows:

PHY_PROFILE: This 3-bit field indicates the PHY profile type of the current frame. The mapping of different PHY profile types is given in below table 5.

【Table 5】

Value	PHY profile
000	Base profile
001	Handheld profile
010	Advanced profiled
011~110	Reserved
111	FEF

FFT_SIZE: This 2 bit field indicates the FFT size of the current frame within a frame-group, as described in below table 6.

【Table 6】

Value	FFT size
00	8K FFT
01	16K FFT
10	32K FFT
11	Reserved

GI_FRACTION: This 3 bit field indicates the guard interval fraction value in the current super-frame, as described in below table 7.

【Table 7】

Value	GI_FRACTION
000	1/5
001	1/10
010	1/20
011	1/40
100	1/80
101	1/160
110~111	Reserved

EAC_FLAG: This 1 bit field indicates whether the EAC is provided in the current frame. If this field is set to '1', emergency alert service (EAS) is provided in the current frame. If this field set to '0', EAS is not carried in the current frame. This field can be switched dynamically within a super-frame.

PILOT_MODE: This 1-bit field indicates whether the pilot mode is mobile mode or fixed mode for the current frame in the current frame-group. If this field is set to '0', mobile pilot mode is used. If the field is set to '1', the fixed pilot mode is used.

PAPR_FLAG: This 1-bit field indicates whether PAPR reduction is used for the current frame in the current frame-group. If this field is set to value '1', tone reservation is used for PAPR reduction. If this field is set to '0', PAPR reduction is not used.

FRU_CONFIGURE: This 3-bit field indicates the PHY profile type configurations of the frame repetition units (FRU) that are present in the current super-frame. All profile types conveyed in the current super-frame are identified in this field in all preambles in the current super-frame. The 3-bit field has a different definition for each profile, as show in below table 8.

【Table 8】

	Current PHY_PROFILE = '000' (base)	Current PHY_PROFILE = '001' (handheld)	Current PHY_PROFILE = '010' (advanced)	Current PHY_PROFILE = '111' (FEF)
FRU_CONFIGURE = 000	Only base profile present	Only handheld profile present	Only advanced profile present	Only FEF present
FRU_CONFIGURE = 1XX	Handheld profile present	Base profile present	Base profile present	Base profile present
FRU_CONFIGURE = X1X	Advanced profile present	Advanced profile present	Handheld profile present	Handheld profile present
FRU_CONFIGURE = XX1	FEF present	FEF present	FEF present	Advanced profile present

RESERVED: This 7-bit field is reserved for future use.

FIG. 13 illustrates PLS1 data according to an embodiment of the present invention.

PLS1 data provides basic transmission parameters including parameters required to enable the reception and decoding of the PLS2. As above mentioned, the PLS1 data remain unchanged for the entire duration of one frame-group. The detailed definition of the signaling fields of the PLS1 data are as follows:

PREAMBLE_DATA: This 20-bit field is a copy of the preamble signaling data excluding the EAC_FLAG.

NUM_FRAME_FRU: This 2-bit field indicates the number of the frames per FRU.

PAYLOAD_TYPE: This 3-bit field indicates the format of the payload data carried in the frame-group. PAYLOAD_TYPE is signaled as shown in table 9.

【Table 9】

value	Payload type
1XX	TS stream is transmitted
X1X	IP stream is transmitted
XX1	GS stream is transmitted

NUM_FSS: This 2-bit field indicates the number of FSS symbols in the current frame.

SYSTEM_VERSION: This 8-bit field indicates the version of the transmitted signal format. The SYSTEM_VERSION is divided into two 4-bit fields, which are a major version and a minor version.

Major version: The MSB four bits of SYSTEM_VERSION field indicate major version information. A change in the major version field indicates a non-backward-compatible change. The default

value is '0000'. For the version described in this standard, the value is set to '0000'.

Minor version: The LSB four bits of SYSTEM_VERSION field indicate minor version information. A change in the minor version field is backward-compatible.

CELL_ID: This is a 16-bit field which uniquely identifies a geographic cell in an ATSC network. An ATSC cell coverage area may consist of one or more frequencies, depending on the number of frequencies used per Futurecast UTB system. If the value of the CELL_ID is not known or unspecified, this field is set to '0'.

NETWORK_ID: This is a 16-bit field which uniquely identifies the current ATSC network.

SYSTEM_ID: This 16-bit field uniquely identifies the Futurecast UTB system within the ATSC network. The Futurecast UTB system is the terrestrial broadcast system whose input is one or more input streams (TS, IP, GS) and whose output is an RF signal. The Futurecast UTB system carries one or more PHY profiles and FEF, if any. The same Futurecast UTB system may carry different input streams and use different RF frequencies in different geographical areas, allowing local service insertion. The frame structure and scheduling is controlled in one place and is identical for all transmissions within a Futurecast UTB system. One or more Futurecast UTB systems may have the same SYSTEM_ID meaning that they all have the same physical layer structure and configuration.

The following loop consists of FRU_PHY_PROFILE, FRU_FRAME_LENGTH, FRU_GI_FRACTION, and RESERVED which are used to indicate the FRU configuration and the length of each frame type. The loop size is fixed so that four PHY profiles (including a FEF) are signaled within the FRU. If NUM_FRAME_FRU is less than 4, the unused fields are filled with zeros.

FRU_PHY_PROFILE: This 3-bit field indicates the PHY profile type of the $(i+1)^{\text{th}}$ (i is the loop index) frame of the associated FRU. This field uses the same signaling format as shown in the table 8.

FRU_FRAME_LENGTH: This 2-bit field indicates the length of the $(i+1)^{\text{th}}$ frame of the associated FRU. Using FRU_FRAME_LENGTH together with FRU_GI_FRACTION, the exact value of the frame duration can be obtained.

FRU_GI_FRACTION: This 3-bit field indicates the guard interval fraction value of the $(i+1)^{\text{th}}$ frame of the associated FRU. FRU_GI_FRACTION is signaled according to the table 7.

RESERVED: This 4-bit field is reserved for future use.

The following fields provide parameters for decoding the PLS2 data.

PLS2_FEC_TYPE: This 2-bit field indicates the FEC type used by the PLS2 protection. The FEC type is signaled according to table 10. The details of the LDPC codes will be described later.

【Table 10】

Content	PLS2 FEC type
00	4K-1/4 and 7K-3/10 LDPC codes
01 ~ 11	Reserved

PLS2_MOD: This 3-bit field indicates the modulation type used by the PLS2. The modulation type is signaled according to table 11.

【Table 11】

Value	PLS2_MODE
000	BPSK
001	QPSK
010	QAM-16
011	NUQ-64
100~111	Reserved

PLS2_SIZE_CELL: This 15-bit field indicates $C_{total_partial_block}$ the size (specified as the number of QAM cells) of the collection of *full* coded blocks for PLS2 that is carried in the current frame-group. This value is constant during the entire duration of the current frame-group.

PLS2_STAT_SIZE_BIT: This 14-bit field indicates the size, in bits, of the PLS2-STAT for the current frame-group. This value is constant during the entire duration of the current frame-group.

PLS2_DYN_SIZE_BIT: This 14-bit field indicates the size, in bits, of the PLS2-DYN for the current frame-group. This value is constant during the entire duration of the current frame-group.

PLS2_REP_FLAG: This 1-bit flag indicates whether the PLS2 repetition mode is used in the current frame-group. When this field is set to value '1', the PLS2 repetition mode is activated. When this field is set to value '0', the PLS2 repetition mode is deactivated.

PLS2_REP_SIZE_CELL: This 15-bit field indicates $C_{total_partial_block}$ the size (specified as the number of QAM cells) of the collection of *partial* coded blocks for PLS2 carried in every frame of the current frame-group, when PLS2 repetition is used. If repetition is not used, the value of this field is equal to 0. This value is constant during the entire duration of the current frame-group.

PLS2_NEXT_FEC_TYPE: This 2-bit field indicates the FEC type used for PLS2 that is carried in every frame of the next frame-group. The FEC type is signaled according to the table 10.

PLS2_NEXT_MOD: This 3-bit field indicates the modulation type used for PLS2 that is carried in every frame of the next frame-group. The modulation type is signaled according to the table 11.

PLS2_NEXT_REP_FLAG: This 1-bit flag indicates whether the PLS2 repetition mode is used in the next frame-group. When this field is set to value '1', the PLS2 repetition mode is activated. When this field is set to value '0', the PLS2 repetition mode is deactivated.

PLS2_NEXT_REP_SIZE_CELL: This 15-bit field indicates $C_{total_full_block}$. The size (specified as the number of QAM cells) of the collection of full coded blocks for PLS2 that is carried in every frame of the next frame-group, when PLS2 repetition is used. If repetition is not used in the next frame-group, the value of this field is equal to 0. This value is constant during the entire duration of the current frame-group.

PLS2_NEXT_REP_STAT_SIZE_BIT: This 14-bit field indicates the size, in bits, of the PLS2-STAT for the next frame-group. This value is constant in the current frame-group.

PLS2_NEXT_REP_DYN_SIZE_BIT: This 14-bit field indicates the size, in bits, of the PLS2-DYN for the next frame-group. This value is constant in the current frame-group.

PLS2_AP_MODE: This 2-bit field indicates whether additional parity is provided for PLS2 in the current frame-group. This value is constant during the entire duration of the current frame-group. The below table 12 gives the values of this field. When this field is set to '00', additional parity is not used for the PLS2 in the current frame-group.

【Table 12】

Value	PLS2-AP mode
00	AP is not provided
01	AP1 mode
10~11	Reserved

PLS2_AP_SIZE_CELL: This 15-bit field indicates the size (specified as the number of QAM cells) of the additional parity bits of the PLS2. This value is constant during the entire duration of the current frame-group.

PLS2_NEXT_AP_MODE: This 2-bit field indicates whether additional parity is provided for PLS2 signaling in every frame of next frame-group. This value is constant during the entire duration of the current frame-group. The table 12 defines the values of this field

PLS2_NEXT_AP_SIZE_CELL: This 15-bit field indicates the size (specified as the number of QAM cells) of the additional parity bits of the PLS2 in every frame of the next frame-group. This value is constant during the entire duration of the current frame-group.

RESERVED: This 32-bit field is reserved for future use.

CRC_32: A 32-bit error detection code, which is applied to the entire PLS1 signaling.

FIG. 14 illustrates PLS2 data according to an embodiment of the present invention.

FIG. 14 illustrates PLS2-STAT data of the PLS2 data. The PLS2-STAT data are the same within a frame-group, while the PLS2-DYN data provide information that is specific for the current frame.

The details of fields of the PLS2-STAT data are as follows:

FIC_FLAG: This 1-bit field indicates whether the FIC is used in the current frame-group. If this field is set to '1', the FIC is provided in the current frame. If this field set to '0', the FIC is not carried in the current frame. This value is constant during the entire duration of the current frame-group.

AUX_FLAG: This 1-bit field indicates whether the auxiliary stream(s) is used in the current frame-group. If this field is set to '1', the auxiliary stream is provided in the current frame. If this field set to '0', the auxiliary stream is not carried in the current frame. This value is constant during the entire duration of current frame-group.

NUM_DP: This 6-bit field indicates the number of DPs carried within the current frame. The value of this field ranges from 1 to 64, and the number of DPs is NUM_DP+1.

DP_ID: This 6-bit field identifies uniquely a DP within a PHY profile.

DP_TYPE: This 3-bit field indicates the type of the DP. This is signaled according to the below table 13.

【Table 13】

Value	DP Type
000	DP Type 1
001	DP Type 2
010~111	reserved

DP_GROUP_ID: This 8-bit field identifies the DP group with which the current DP is associated. This can be used by a receiver to access the DPs of the service components associated with a particular service, which will have the same DP_GROUP_ID.

BASE_DP_ID: This 6-bit field indicates the DP carrying service signaling data (such as PSI/SI) used in the Management layer. The DP indicated by BASE_DP_ID may be either a normal DP carrying the service signaling data along with the service data or a dedicated DP carrying only the service signaling data

DP_FEC_TYPE: This 2-bit field indicates the FEC type used by the associated DP. The FEC type is signaled according to the below table 14.

【Table 14】

Value	FEC_TYPE
00	16K LDPC
01	64K LDPC
10 ~ 11	Reserved

DP_COD: This 4-bit field indicates the code rate used by the associated DP. The code rate is signaled according to the below table 15.

【Table 15】

Value	Code rate
0000	5/15
0001	6/15
0010	7/15
0011	8/15
0100	9/15
0101	10/15
0110	11/15
0111	12/15
1000	13/15
1001 ~ 1111	Reserved

DP_MOD: This 4-bit field indicates the modulation used by the associated DP. The modulation is signaled according to the below table 16.

【Table 16】

Value	Modulation
0000	QPSK
0001	QAM-16
0010	NUQ-64
0011	NUQ-256
0100	NUQ-1024
0101	NUC-16
0110	NUC-64
0111	NUC-256
1000	NUC-1024
1001~1111	reserved

DP_SSD_FLAG: This 1-bit field indicates whether the SSD mode is used in the associated DP. If this field is

set to value '1', SSD is used. If this field is set to value '0', SSD is not used.

The following field appears only if PHY_PROFILE is equal to '010', which indicates the advanced profile:

DP_MIMO: This 3-bit field indicates which type of MIMO encoding process is applied to the associated DP. The type of MIMO encoding process is signaled according to the table 17.

【Table 17】

Value	MIMO encoding
000	FR-SM
001	FRFD-SM
010~111	reserved

DP_TI_TYPE: This 1-bit field indicates the type of time-interleaving. A value of '0' indicates that one TI group corresponds to one frame and contains one or more TI-blocks. A value of '1' indicates that one TI group is carried in more than one frame and contains only one TI-block.

DP_TI_LENGTH: The use of this 2-bit field (the allowed values are only 1, 2, 4, 8) is determined by the values set within the DP_TI_TYPE field as follows:

If the DP_TI_TYPE is set to the value '1', this field indicates P_I , the number of the frames to which each TI group is mapped, and there is one TI-block per TI group ($N_{TI}=1$). The allowed P_I values with 2-bit field are defined in the below table 18.

If the DP_TI_TYPE is set to the value '0', this field indicates the number of TI-blocks N_{TI} per TI group, and there is one TI group per frame ($P_I=1$). The allowed P_I values with 2-bit field are defined in the below table 18.

【Table 18】

2-bit field	P_I	N_{TI}
00	1	1
01	2	2
10	4	3
11	8	4

DP_FRAME_INTERVAL: This 2-bit field indicates the frame interval (I_{JUMP}) within the frame-group for the associated DP and the allowed values are 1, 2, 4, 8 (the corresponding 2-bit field is '00', '01', '10', or '11', respectively). For DPs that do not appear every frame of the frame-group, the value of this field is equal to the interval between successive frames. For example, if a DP appears on the frames 1, 5, 9, 13, etc.,

this field is set to '4'. For DPs that appear in every frame, this field is set to '1'.

DP_TI_BYPASS: This 1-bit field determines the availability of time interleaver. If time interleaving is not used for a DP, it is set to '1'. Whereas if time interleaving is used it is set to '0'.

DP_FIRST_FRAME_IDX: This 5-bit field indicates the index of the first frame of the super-frame in which the current DP occurs. The value of DP_FIRST_FRAME_IDX ranges from 0 to 31

DP_NUM_BLOCK_MAX: This 10-bit field indicates the maximum value of DP_NUM_BLOCKS for this DP. The value of this field has the same range as DP_NUM_BLOCKS.

DP_PAYLOAD_TYPE: This 2-bit field indicates the type of the payload data carried by the given DP.

DP_PAYLOAD_TYPE is signaled according to the below table 19.

【Table 19】

Value	Payload Type
00	TS.
01	IP
10	GS
11	reserved

DP_INBAND_MODE: This 2-bit field indicates whether the current DP carries in-band signaling information. The in-band signaling type is signaled according to the below table 20.

【Table 20】

Value	In-band mode
00	In-band signaling is not carried.
01	INBAND-PLS is carried only
10	INBAND-ISSY is carried only
11	INBAND-PLS and INBAND-ISSY are carried

DP_PROTOCOL_TYPE: This 2-bit field indicates the protocol type of the payload carried by the given DP. It is signaled according to the below table 21 when input payload types are selected.

【Table 21】

Value	If DP_PAYLOAD_TYPE Is TS	If DP_PAYLOAD_TYPE Is IP	If DP_PAYLOAD_TYPE Is GS
00	MPEG2-TS	IPv4	(Note)
01	Reserved	IPv6	Reserved
10	Reserved	Reserved	Reserved
11	Reserved	Reserved	Reserved

DP_CRC_MODE: This 2-bit field indicates whether CRC encoding is used in the Input Formatting block. The CRC mode is signaled according to the below table 22.

【Table 22】

Value	CRC mode
00	Not used
01	CRC-8
10	CRC-16
11	CRC-32

DNP_MODE: This 2-bit field indicates the null-packet deletion mode used by the associated DP when DP_PAYLOAD_TYPE is set to TS ('00'). DNP_MODE is signaled according to the below table 23. If DP_PAYLOAD_TYPE is not TS ('00'), DNP_MODE is set to the value '00'.

【Table 23】

Value	Null-packet deletion mode
00	Not used
01	DNP-NORMAL
10	DNP-OFFSET
11	reserved

ISSY_MODE: This 2-bit field indicates the ISSY mode used by the associated DP when DP_PAYLOAD_TYPE is set to TS ('00'). The ISSY_MODE is signaled according to the below table 24 If DP_PAYLOAD_TYPE is not TS ('00'), ISSY_MODE is set to the value '00'.

【Table 24】

Value	ISSY mode
00	Not used
01	ISSY-UP
10	ISSY-BBF
11	reserved

HC_MODE_TS: This 2-bit field indicates the TS header compression mode used by the associated DP when DP_PAYLOAD_TYPE is set to TS ('00'). The HC_MODE_TS is signaled according to the below table 25.

【Table 25】

Value	Header compression mode
00	HC_MODE_TS 1
01	HC_MODE_TS 2
10	HC_MODE_TS 3
11	HC_MODE_TS 4

HC_MODE_IP: This 2-bit field indicates the IP header compression mode when DP_PAYLOAD_TYPE is set to IP ('01'). The HC_MODE_IP is signaled according to the below table 26.

【Table 26】

Value	Header compression mode
00	No compression
01	HC_MODE_IP 1
10~11	reserved

PID : This 13-bit field indicates the PID number for TS header compression when DP_PAYLOAD_TYPE is set to TS ('00') and HC_MODE_TS is set to '01' or '10'.

RESERVED: This 8-bit field is reserved for future use.

The following field appears only if FIC_FLAG is equal to '1':

FIC_VERSION: This 8-bit field indicates the version number of the FIC.

FIC_LENGTH_BYTE: This 13-bit field indicates the length, in bytes, of the FIC.

RESERVED: This 8-bit field is reserved for future use.

The following field appears only if AUX_FLAG is equal to '1':

NUM_AUX: This 4-bit field indicates the number of auxiliary streams. Zero means no auxiliary streams are

used.

AUX_CONFIG_RFU: This 8-bit field is reserved for future use.

AUX_STREAM_TYPE: This 4-bit is reserved for future use for indicating the type of the current auxiliary stream.

AUX_PRIVATE_CONFIG: This 28-bit field is reserved for future use for signaling auxiliary streams.

FIG. 15 illustrates PLS2 data according to another embodiment of the present invention.

FIG. 15 illustrates PLS2-DYN data of the PLS2 data. The values of the PLS2-DYN data may change during the duration of one frame-group, while the size of fields remains constant.

The details of fields of the PLS2-DYN data are as follows:

FRAME_INDEX: This 5-bit field indicates the frame index of the current frame within the super-frame. The index of the first frame of the super-frame is set to '0'.

PLS_CHANGE_COUNTER: This 4-bit field indicates the number of super-frames ahead where the configuration will change. The next super-frame with changes in the configuration is indicated by the value signaled within this field. If this field is set to the value '0000', it means that no scheduled change is foreseen: e.g., value '1' indicates that there is a change in the next super-frame.

FIC_CHANGE_COUNTER: This 4-bit field indicates the number of super-frames ahead where the configuration (i.e., the contents of the FIC) will change. The next super-frame with changes in the configuration is indicated by the value signaled within this field. If this field is set to the value '0000', it means that no scheduled change is foreseen: e.g. value '0001' indicates that there is a change in the next super-frame..

RESERVED: This 16-bit field is reserved for future use.

The following fields appear in the loop over NUM_DP, which describe the parameters associated with the DP carried in the current frame.

DP_ID: This 6-bit field indicates uniquely the DP within a PHY profile.

DP_START: This 15-bit (or 13-bit) field indicates the start position of the first of the DPs using the DPU addressing scheme. The DP_START field has differing length according to the PHY profile and FFT size as shown in the below table 27.

【Table 27】

PHY profile	DP_START field size	
	64K	16K
Base	13 bit	15 bit
Handheld	-	13 bit
Advanced	13 bit	15 bit

DP_NUM_BLOCK: This 10-bit field indicates the number of FEC blocks in the current TI group for the current DP. The value of DP_NUM_BLOCK ranges from 0 to 1023

RESERVED: This 8-bit field is reserved for future use.

The following fields indicate the FIC parameters associated with the EAC.

EAC_FLAG: This 1-bit field indicates the existence of the EAC in the current frame. This bit is the same value as the EAC_FLAG in the preamble.

EAS_WAKE_UP_VERSION_NUM: This 8-bit field indicates the version number of a wake-up indication.

If the EAC_FLAG field is equal to '1', the following 12 bits are allocated for EAC_LENGTH_BYTE field. If the EAC_FLAG field is equal to '0', the following 12 bits are allocated for EAC_COUNTER.

EAC_LENGTH_BYTE: This 12-bit field indicates the length, in byte, of the EAC. .

EAC_COUNTER: This 12-bit field indicates the number of the frames before the frame where the EAC arrives.

The following field appears only if the AUX_FLAG field is equal to '1':

AUX_PRIVATE_DYN: This 48-bit field is reserved for future use for signaling auxiliary streams. The meaning of this field depends on the value of AUX_STREAM_TYPE in the configurable PLS2-STAT.

CRC_32: A 32-bit error detection code, which is applied to the entire PLS2.

FIG. 16 illustrates a logical structure of a frame according to an embodiment of the present invention.

As above mentioned, the PLS, EAC, FIC, DPs, auxiliary streams and dummy cells are mapped into the active carriers of the OFDM symbols in the frame. The PLS1 and PLS2 are first mapped into one or more FSS(s). After that, EAC cells, if any, are mapped immediately following the PLS field, followed next by FIC cells, if any. The DPs are mapped next after the PLS or EAC, FIC, if any. Type 1 DPs follows first, and Type 2 DPs next. The details of a type of the DP will be described later. In some case, DPs may carry some special data for EAS or service signaling data. The auxiliary stream or streams, if any, follow the DPs, which in turn are followed by dummy cells. Mapping them all together in the above mentioned order, i.e. PLS, EAC, FIC, DPs, auxiliary streams and dummy data cells exactly fill the cell capacity in the frame.

FIG. 17 illustrates PLS mapping according to an embodiment of the present invention.

PLS cells are mapped to the active carriers of FSS(s). Depending on the number of cells occupied by PLS, one or more symbols are designated as FSS(s), and the number of FSS(s) N_{FSS} is signaled by NUM_FSS in PLS1. The FSS is a special symbol for carrying PLS cells. Since robustness and latency are critical issues in the PLS, the FSS(s) has higher density of pilots allowing fast synchronization and frequency-only interpolation within the FSS.

PLS cells are mapped to active carriers of the N_{FSS} FSS(s) in a top-down manner as shown in an example in FIG. 17. The PLS1 cells are mapped first from the first cell of the first FSS in an increasing order of the cell index. The PLS2 cells follow immediately after the last cell of the PLS1 and mapping continues downward until the last cell index of the first FSS. If the total number of required PLS cells exceeds the number of active carriers of one FSS, mapping proceeds to the next FSS and continues in exactly the same manner as the first FSS.

After PLS mapping is completed, DPs are carried next. If EAC, FIC or both are present in the current frame, they are placed between PLS and "normal" DPs.

FIG. 18 illustrates EAC mapping according to an embodiment of the present invention.

EAC is a dedicated channel for carrying EAS messages and links to the DPs for EAS. EAS support is provided but EAC itself may or may not be present in every frame. EAC, if any, is mapped immediately after the PLS2 cells. EAC is not preceded by any of the FIC, DPs, auxiliary streams or dummy cells other than the PLS cells. The procedure of mapping the EAC cells is exactly the same as that of the PLS.

The EAC cells are mapped from the next cell of the PLS2 in increasing order of the cell index as shown in the example in FIG. 18. Depending on the EAS message size, EAC cells may occupy a few symbols, as shown in FIG. 18.

EAC cells follow immediately after the last cell of the PLS2, and mapping continues downward until the last cell index of the last FSS. If the total number of required EAC cells exceeds the number of remaining active carriers of the last FSS mapping proceeds to the next symbol and continues in exactly the same manner as FSS(s). The next symbol for mapping in this case is the normal data symbol, which has more active carriers than a FSS.

After EAC mapping is completed, the FIC is carried next, if any exists. If FIC is not transmitted (as signaled in the PLS2 field), DPs follow immediately after the last cell of the EAC.

FIG. 19 illustrates FIC mapping according to an embodiment of the present invention.

(a) shows an example mapping of FIC cell without EAC and (b) shows an example mapping of FIC cell with EAC.

FIC is a dedicated channel for carrying cross-layer information to enable fast service acquisition and

channel scanning. This information primarily includes channel binding information between DPs and the services of each broadcaster. For fast scan, a receiver can decode FIC and obtain information such as broadcaster ID, number of services, and BASE_DP_ID. For fast service acquisition, in addition to FIC, base DP can be decoded using BASE_DP_ID. Other than the content it carries, a base DP is encoded and mapped to a frame in exactly the same way as a normal DP. Therefore, no additional description is required for a base DP. The FIC data is generated and consumed in the Management Layer. The content of FIC data is as described in the Management Layer specification.

The FIC data is optional and the use of FIC is signaled by the FIC_FLAG parameter in the static part of the PLS2. If FIC is used, FIC_FLAG is set to '1' and the signaling field for FIC is defined in the static part of PLS2. Signaled in this field are FIC_VERSION, and FIC_LENGTH_BYTE. FIC uses the same modulation, coding and time interleaving parameters as PLS2. FIC shares the same signaling parameters such as PLS2_MOD and PLS2_FEC. FIC data, if any, is mapped immediately after PLS2 or EAC if any. FIC is not preceded by any normal DPs, auxiliary streams or dummy cells. The method of mapping FIC cells is exactly the same as that of EAC which is again the same as PLS.

Without EAC after PLS, FIC cells are mapped from the next cell of the PLS2 in an increasing order of the cell index as shown in an example in (a). Depending on the FIC data size, FIC cells may be mapped over a few symbols, as shown in (b).

FIC cells follow immediately after the last cell of the PLS2, and mapping continues downward until the last cell index of the last FSS. If the total number of required FIC cells exceeds the number of remaining active carriers of the last FSS, mapping proceeds to the next symbol and continues in exactly the same manner as FSS(s). The next symbol for mapping in this case is the normal data symbol which has more active carriers than a FSS.

If EAS messages are transmitted in the current frame, EAC precedes FIC, and FIC cells are mapped from the next cell of the EAC in an increasing order of the cell index as shown in (b).

After FIC mapping is completed, one or more DPs are mapped, followed by auxiliary streams, if any, and dummy cells.

FIG. 20 illustrates a type of DP according to an embodiment of the present invention.

(a) shows type 1 DP and (b) shows type 2 DP.

After the preceding channels, i.e., PLS, EAC and FIC, are mapped, cells of the DPs are mapped. A DP is categorized into one of two types according to mapping method:

Type 1 DP: DP is mapped by TDM

Type 2 DP: DP is mapped by FDM

The type of DP is indicated by DP_TYPE field in the static part of PLS2. FIG. 20 illustrates the mapping orders of Type 1 DPs and Type 2 DPs. Type 1 DPs are first mapped in the increasing order of cell index, and then after reaching the last cell index, the symbol index is increased by one. Within the next symbol, the DP continues to be mapped in the increasing order of cell index starting from $p = 0$. With a number of DPs mapped together in one frame, each of the Type 1 DPs are grouped in time, similar to TDM multiplexing of DPs.

Type 2 DPs are first mapped in the increasing order of symbol index, and then after reaching the last OFDM symbol of the frame, the cell index increases by one and the symbol index rolls back to the first available symbol and then increases from that symbol index. After mapping a number of DPs together in one frame, each of the Type 2 DPs are grouped in frequency together, similar to FDM multiplexing of DPs. Type 1 DPs and Type 2 DPs can coexist in a frame if needed with one restriction; Type 1 DPs always precede Type 2 DPs. The total number of OFDM cells carrying Type 1 and Type 2 DPs cannot exceed the total number of OFDM cells available for transmission of DPs:

【Math Figure 2】

$$D_{DP1} + D_{DP2} \leq D_{DP}$$

where D_{DP1} is the number of OFDM cells occupied by Type 1 DPs, D_{DP2} is the number of cells occupied by Type 2 DPs. Since PLS, EAC, FIC are all mapped in the same way as Type 1 DP, they all follow “Type 1 mapping rule”. Hence, overall, Type 1 mapping always precedes Type 2 mapping.

FIG. 21 illustrates DP mapping according to an embodiment of the present invention.

(a) shows an addressing of OFDM cells for mapping type 1 DPs and (b) shows an an addressing of OFDM cells for mapping for type 2 DPs.

Addressing of OFDM cells for mapping Type 1 DPs ($0, \dots, D_{DP1}-1$) is defined for the active data cells of Type 1 DPs. The addressing scheme defines the order in which the cells from the TIs for each of the Type 1 DPs are allocated to the active data cells. It is also used to signal the locations of the DPs in the dynamic part of the PLS2.

Without EAC and FIC, address 0 refers to the cell immediately following the last cell carrying PLS in the last FSS. If EAC is transmitted and FIC is not in the corresponding frame, address 0 refers to the cell immediately following the last cell carrying EAC. If FIC is transmitted in the corresponding frame, address 0 refers to the cell immediately following the last cell carrying FIC. Address 0 for Type 1 DPs can be calculated considering two different cases as shown in (a). In the example in (a), PLS, EAC and FIC are assumed to be all transmitted. Extension to the cases where either or both of EAC and FIC are omitted is

straightforward. If there are remaining cells in the FSS after mapping all the cells up to FIC as shown on the left side of (a).

Addressing of OFDM cells for mapping Type 2 DPs ($0, \dots, D_{DP2}-1$) is defined for the active data cells of Type 2 DPs. The addressing scheme defines the order in which the cells from the TIs for each of the Type 2 DPs are allocated to the active data cells. It is also used to signal the locations of the DPs in the dynamic part of the PLS2.

Three slightly different cases are possible as shown in (b). For the first case shown on the left side of (b), cells in the last FSS are available for Type 2 DP mapping. For the second case shown in the middle, FIC occupies cells of a normal symbol, but the number of FIC cells on that symbol is not larger than C_{FSS} . The third case, shown on the right side in (b), is the same as the second case except that the number of FIC cells mapped on that symbol exceeds C_{FSS} .

The extension to the case where Type 1 DP(s) precede Type 2 DP(s) is straightforward since PLS, EAC and FIC follow the same "Type 1 mapping rule" as the Type 1 DP(s).

A data pipe unit (DPU) is a basic unit for allocating data cells to a DP in a frame.

A DPU is defined as a signaling unit for locating DPs in a frame. A Cell Mapper 7010 may map the cells produced by the TIs for each of the DPs. A Time interleaver 5050 outputs a series of TI-blocks and each TI-block comprises a variable number of XFECBLOCKs which is in turn composed of a set of cells. The number of cells in an XFECBLOCK, N_{cells} , is dependent on the FECBLOCK size, N_{ldpc} , and the number of transmitted bits per constellation symbol. A DPU is defined as the greatest common divisor of all possible values of the number of cells in a XFECBLOCK, N_{cells} , supported in a given PHY profile. The length of a DPU in cells is defined as L_{DPU} . Since each PHY profile supports different combinations of FECBLOCK size and a different number of bits per constellation symbol, L_{DPU} is defined on a PHY profile basis.

FIG. 22 illustrates an FEC structure according to an embodiment of the present invention.

FIG. 22 illustrates an FEC structure according to an embodiment of the present invention before bit interleaving. As above mentioned, Data FEC encoder may perform the FEC encoding on the input BBF to generate FECBLOCK procedure using outer coding (BCH), and inner coding (LDPC). The illustrated FEC structure corresponds to the FECBLOCK. Also, the FECBLOCK and the FEC structure have same value corresponding to a length of LDPC codeword.

The BCH encoding is applied to each BBF (K_{bch} bits), and then LDPC encoding is applied to BCH-encoded BBF (K_{ldpc} bits = N_{bch} bits) as illustrated in FIG. 22.

The value of N_{ldpc} is either 64800 bits (long FECBLOCK) or 16200 bits (short FECBLOCK).

The below table 28 and table 29 show FEC encoding parameters for a long FECBLOCK and a short FECBLOCK, respectively.

【Table 28】

LDPC Rate	N_{ldpc}	K_{ldpc}	K_{bch}	BCH error correction capability	$N_{bch}-K_{bch}$
5/15	64800	21600	21408	12	192
6/15		25920	25728		
7/15		30240	30048		
8/15		34560	34368		
9/15		38880	38688		
10/15		43200	43008		
11/15		47520	47328		
12/15		51840	51648		
13/15		56160	55968		

【Table 29】

LDPC Rate	N_{ldpc}	K_{ldpc}	K_{bch}	BCH error correction capability	$N_{bch}-K_{bch}$
5/15	16200	5400	5232	12	168
6/15		6480	6312		
7/15		7560	7392		
8/15		8640	8472		
9/15		9720	9552		
10/15		10800	10632		
11/15		11880	11712		
12/15		12960	12792		
13/15		14040	13872		

The details of operations of the BCH encoding and LDPC encoding are as follows:

A 12-error correcting BCH code is used for outer encoding of the BBF. The BCH generator polynomial for short FECBLOCK and long FECBLOCK are obtained by multiplying together all polynomials.

LDPC code is used to encode the output of the outer BCH encoding. To generate a completed B_{ldpc}

(FECBLOCK), P_{ldpc} (parity bits) is encoded systematically from each I_{ldpc} (BCH-encoded BBF), and appended to I_{ldpc} . The completed B_{ldpc} (FECBLOCK) are expressed as follow Math figure.

【Math Figure 3】

$$B_{ldpc} = [\mathbf{I}_{ldpc} \ \mathbf{P}_{ldpc}] = [i_0, i_1, \dots, i_{K_{ldpc}-1}, p_0, p_1, \dots, p_{N_{ldpc}-K_{ldpc}-1}]$$

The parameters for long FECBLOCK and short FECBLOCK are given in the above table 28 and 29, respectively.

The detailed procedure to calculate $N_{ldpc} - K_{ldpc}$ parity bits for long FECBLOCK, is as follows:

1) Initialize the parity bits,

【Math Figure 4】

$$p_0 = p_1 = p_2 = \dots = p_{N_{ldpc}-K_{ldpc}-1} = 0$$

2) Accumulate the first information bit - i_0 , at parity bit addresses specified in the first row of an addresses of parity check matrix. The details of addresses of parity check matrix will be described later.

For example, for rate 13/15:

【Math Figure 5】

$$\begin{aligned} p_{983} &= p_{983} \oplus i_0 & p_{2815} &= p_{2815} \oplus i_0 \\ p_{4837} &= p_{4837} \oplus i_0 & p_{4989} &= p_{4989} \oplus i_0 \\ p_{6138} &= p_{6138} \oplus i_0 & p_{6458} &= p_{6458} \oplus i_0 \\ p_{6921} &= p_{6921} \oplus i_0 & p_{6974} &= p_{6974} \oplus i_0 \\ p_{7572} &= p_{7572} \oplus i_0 & p_{8260} &= p_{8260} \oplus i_0 \\ p_{8496} &= p_{8496} \oplus i_0 \end{aligned}$$

3) For the next 359 information bits, i_s , $s=1, 2, \dots, 359$ accumulate i_s at parity bit addresses using following Math figure.

【Math Figure 6】

$$\{x + (s \bmod 360) \times Q_{ldpc}\} \bmod (N_{ldpc} - K_{ldpc})$$

where x denotes the address of the parity bit accumulator corresponding to the first bit i_0 , and Q_{ldpc} is a code rate dependent constant specified in the addresses of parity check matrix. Continuing with the example, $Q_{ldpc} = 24$ for rate 13/15, so for information bit i_1 , the following operations are performed:

【Math Figure 7】

$$p_{1007} = p_{1007} \oplus i_1 \quad p_{2839} = p_{2839} \oplus i_1$$

$$p_{4861} = p_{4861} \oplus i_1 \quad p_{5013} = p_{5013} \oplus i_1$$

$$p_{6162} = p_{6162} \oplus i_1 \quad p_{6482} = p_{6482} \oplus i_1$$

$$p_{6945} = p_{6945} \oplus i_1 \quad p_{6998} = p_{6998} \oplus i_1$$

$$p_{7596} = p_{7596} \oplus i_1 \quad p_{8284} = p_{8284} \oplus i_1$$

$$p_{8520} = p_{8520} \oplus i_1$$

4) For the 361st information bit i_{360} , the addresses of the parity bit accumulators are given in the second row of the addresses of parity check matrix. In a similar manner the addresses of the parity bit accumulators for the following 359 information bits i_s , $s = 361, 362, \dots, 719$ are obtained using the Math figure 6, where x denotes the address of the parity bit accumulator corresponding to the information bit i_{360} , i.e., the entries in the second row of the addresses of parity check matrix.

5) In a similar manner, for every group of 360 new information bits, a new row from addresses of parity check matrixes used to find the addresses of the parity bit accumulators.

After all of the information bits are exhausted, the final parity bits are obtained as follows:

6) Sequentially perform the following operations starting with $i=1$

【Math Figure 8】

$$p_i = p_i \oplus p_{i-1}, \quad i = 1, 2, \dots, N_{ldpc} - K_{ldpc} - 1$$

where final content of p_i , $i=0, 1, \dots, N_{ldpc} - K_{ldpc} - 1$ is equal to the parity bit p_i .

【Table 30】

Code Rate	Q_{ldpc}
5/15	120
6/15	108
7/15	96
8/15	84
9/15	72
10/15	60
11/15	48
12/15	36
13/15	24

This LDPC encoding procedure for a short FECBLOCK is in accordance with the LDPC encoding procedure for the long FECBLOCK, except replacing the table 30 with table 31, and replacing the addresses of parity check matrix for the long FECBLOCK with the addresses of parity check matrix for the short FECBLOCK.

【Table 31】

Code Rate	Q_{ldpc}
5/15	30
6/15	27
7/15	24
8/15	21
9/15	18
10/15	15
11/15	12
12/15	9
13/15	6

FIG. 23 illustrates a bit interleaving according to an embodiment of the present invention.

The outputs of the LDPC encoder are bit-interleaved, which consists of parity interleaving followed by Quasi-Cyclic Block (QCB) interleaving and inner-group interleaving.

(a) shows Quasi-Cyclic Block (QCB) interleaving and (b) shows inner-group interleaving.

The FECBLOCK may be parity interleaved. At the output of the parity interleaving, the LDPC codeword consists of 180 adjacent QC blocks in a long FECBLOCK and 45 adjacent QC blocks in a short FECBLOCK.

Each QC block in either a long or short FECBLOCK consists of 360 bits. The parity interleaved LDPC codeword is interleaved by QCB interleaving. The unit of QCB interleaving is a QC block. The QC blocks at the output of parity interleaving are permuted by QCB interleaving as illustrated in FIG. 23, where $N_{\text{cells}} = 64800/\eta_{\text{mod}}$ or $16200/\eta_{\text{mod}}$ according to the FECBLOCK length. The QCB interleaving pattern is unique to each combination of modulation type and LDPC code rate.

After QCB interleaving, inner-group interleaving is performed according to modulation type and order (η_{mod}) which is defined in the below table 32. The number of QC blocks for one inner-group, $N_{\text{QCB_IG}}$ is also defined.

【Table 32】

Modulation type	η_{mod}	$N_{\text{QCB_IG}}$
QAM-16	4	2
NUC-16	4	4
NUQ-64	6	3
NUC-64	6	6
NUQ-256	8	4
NUC-256	8	8
NUQ-1024	10	5
NUC-1024	10	10

The inner-group interleaving process is performed with $N_{\text{QCB_IG}}$ QC blocks of the QCB interleaving output. Inner-group interleaving has a process of writing and reading the bits of the inner-group using 360 columns and $N_{\text{QCB_IG}}$ rows. In the write operation, the bits from the QCB interleaving output are written row-wise. The read operation is performed column-wise to read out m bits from each row, where m is equal to 1 for NUC and 2 for NUQ.

FIG. 24 illustrates a cell-word demultiplexing according to an embodiment of the present invention.

(a) shows a cell-word demultiplexing for 8 and 12 bpcu MIMO and (b) shows a cell-word demultiplexing for 10 bpcu MIMO.

Each cell word $(c_{0,l}, c_{1,l}, \dots, c_{\eta_{\text{mod}}-1,l})$ of the bit interleaving output is demultiplexed into $(d_{1,0,m}, d_{1,1,m}, \dots, d_{1,\eta_{\text{mod}}-1,m})$ and $(d_{2,0,m}, d_{2,1,m}, \dots, d_{2,\eta_{\text{mod}}-1,m})$ as shown in (a), which describes the cell-word demultiplexing process for one XFECBLOCK.

For the 10 bpcu MIMO case using different types of NUQ for MIMO encoding, the Bit Interleaver for

NUQ-1024 is re-used. Each cell word $(c_{0,l}, c_{1,l}, \dots, c_{9,l})$ of the Bit Interleaver output is demultiplexed into $(d'_{1,0,m}, d'_{1,1,m}, \dots, d'_{1,3,m})$ and $(d'_{2,0,m}, d'_{2,1,m}, \dots, d'_{2,5,m})$, as shown in (b).

FIG. 25 illustrates a time interleaving according to an embodiment of the present invention.

(a) to (c) show examples of TI mode.

The time interleaver operates at the DP level. The parameters of time interleaving (TI) may be set differently for each DP.

The following parameters, which appear in part of the PLS2-STAT data, configure the TI:

DP_TI_TYPE (allowed values: 0 or 1): Represents the TI mode; '0' indicates the mode with multiple TI blocks (more than one TI block) per TI group. In this case, one TI group is directly mapped to one frame (no inter-frame interleaving). '1' indicates the mode with only one TI block per TI group. In this case, the TI block may be spread over more than one frame (inter-frame interleaving).

DP_TI_LENGTH: If DP_TI_TYPE = '0', this parameter is the number of TI blocks N_{TI} per TI group. For DP_TI_TYPE = '1', this parameter is the number of frames P_1 spread from one TI group.

DP_NUM_BLOCK_MAX (allowed values: 0 to 1023): Represents the maximum number of XFECBLOCKs per TI group.

DP_FRAME_INTERVAL (allowed values: 1, 2, 4, 8): Represents the number of the frames I_{JUMP} between two successive frames carrying the same DP of a given PHY profile.

DP_TI_BYPASS (allowed values: 0 or 1): If time interleaving is not used for a DP, this parameter is set to '1'. It is set to '0' if time interleaving is used.

Additionally, the parameter DP_NUM_BLOCK from the PLS2-DYN data is used to represent the number of XFECBLOCKs carried by one TI group of the DP.

When time interleaving is not used for a DP, the following TI group, time interleaving operation, and TI mode are not considered. However, the Delay Compensation block for the dynamic configuration information from the scheduler will still be required. In each DP, the XFECBLOCKs received from the SSD/MIMO encoding are grouped into TI groups. That is, each TI group is a set of an integer number of XFECBLOCKs and will contain a dynamically variable number of XFECBLOCKs. The number of XFECBLOCKs in the TI group of index n is denoted by $N_{xBLOCK_Group}(n)$ and is signaled as DP_NUM_BLOCK in the PLS2-DYN data. Note that $N_{xBLOCK_Group}(n)$ may vary from the minimum value of 0 to the maximum value $N_{xBLOCK_Group_MAX}$ (corresponding to DP_NUM_BLOCK_MAX) of which the largest value is 1023.

Each TI group is either mapped directly onto one frame or spread over P_1 frames. Each TI group is also divided into more than one TI blocks(N_{TI}), where each TI block corresponds to one usage of time interleaver memory. The TI blocks within the TI group may contain slightly different numbers of

XFECBLOCKs. If the TI group is divided into multiple TI blocks, it is directly mapped to only one frame. There are three options for time interleaving (except the extra option of skipping the time interleaving) as shown in the below table 33.

【Table 33】

Modes	Descriptions
Option-1	Each TI group contains one TI block and is mapped directly to one frame as shown in (a). This option is signaled in the PLS2-STAT by DP_TI_TYPE='0' and DP_TI_LENGTH='1' ($N_{TI}=1$).
Option-2	Each TI group contains one TI block and is mapped to more than one frame. (b) shows an example, where one TI group is mapped to two frames, i.e., DP_TI_LENGTH='2' ($P_I=2$) and DP_FRAME_INTERVAL ($I_{JUMP} = 2$). This provides greater time diversity for low data-rate services. This option is signaled in the PLS2-STAT by DP_TI_TYPE='1'.
Option-3	Each TI group is divided into multiple TI blocks and is mapped directly to one frame as shown in (c). Each TI block may use full TI memory, so as to provide the maximum bit-rate for a DP. This option is signaled in the PLS2-STAT signaling by DP_TI_TYPE='0' and DP_TI_LENGTH = N_{TI} , while $P_I=1$.

In each DP, the TI memory stores the input XFECBLOCKs (output XFECBLOCKs from the SSD/MIMO encoding block). Assume that input XFECBLOCKs are defined as

$$(d_{n,s,0,0}, d_{n,s,0,1}, \dots, d_{n,s,0,N_{cells}-1}, d_{n,s,1,0}, \dots, d_{n,s,1,N_{cells}-1}, \dots, d_{n,s,N_{xBLOCK_TI}(n,s)-1,0}, \dots, d_{n,s,N_{xBLOCK_TI}(n,s)-1,N_{cells}-1}),$$

where $d_{n,s,r,q}$ is the qth cell of the rth XFECBLOCK in the sth TI block of the nth TI group and represents the outputs of SSD and MIMO encodings as follows.

$$d_{n,s,r,q} = \begin{cases} f_{n,s,r,q} & , \text{the output of SSD encoding} \\ g_{n,s,r,q} & , \text{the output of MIMO encoding} \end{cases}$$

In addition, assume that output XFECBLOCKs from the time interleaver are defined as

$$(h_{n,s,0}, h_{n,s,1}, \dots, h_{n,s,i}, \dots, h_{n,s,N_{xBLOCK_TI}(n,s) \times N_{cells}-1})$$

where $h_{n,s,i}$ is the ith output cell (for $i = 0, \dots, N_{xBLOCK_TI}(n,s) \times N_{cells} - 1$) in the sth TI block of the nth TI group.

Typically, the time interleaver will also act as a buffer for DP data prior to the process of frame building. This is achieved by means of two memory banks for each DP. The first TI-block is written to the first bank. The second TI-block is written to the second bank while the first bank is being read from and so on.

The TI is a twisted row-column block interleaver. For the s th TI block of the n th TI group, the number of rows N_r of a TI memory is equal to the number of cells N_{cells} , i.e., $N_r = N_{cells}$ while the number of columns N_c is equal to the number $N_{xBLOCK_TI}(n,s)$.

FIG. 26 illustrates the basic operation of a twisted row-column block interleaver according to an embodiment of the present invention.

shows a writing operation in the time interleaver and (b) shows a reading operation in the time interleaver. The first XFECBLOCK is written column-wise into the first column of the TI memory, and the second XFECBLOCK is written into the next column, and so on as shown in (a). Then, in the interleaving array, cells are read out diagonal-wise. During diagonal-wise reading from the first row (rightwards along the row beginning with the left-most column) to the last row, N_r cells are read out as shown in (b). In detail, assuming $z_{n,s,i}(i = 0, \dots, N_r N_c)$ as the TI memory cell position to be read sequentially, the reading process in such an interleaving array is performed by calculating the row index $R_{n,s,i}$, the column index $C_{n,s,i}$, and the associated twisting parameter $T_{n,s,i}$ as follows expression.

【Math Figure 9】

$$\begin{aligned} & GENERATE(R_{n,s,i}, C_{n,s,i}) = \\ & \{ \\ & R_{n,s,i} = \text{mod}(i, N_r), \\ & T_{n,s,i} = \text{mod}(S_{shift} \times R_{n,s,i}, N_c), \\ & C_{n,s,i} = \text{mod}(T_{n,s,i} + \left\lfloor \frac{i}{N_r} \right\rfloor, N_c) \\ & \} \end{aligned}$$

where S_{shift} is a common shift value for the diagonal-wise reading process regardless of $N_{xBLOCK_TI}(n,s)$, and it is determined by $N_{xBLOCK_TI_MAX}$ given in the PLS2-STAT as follows expression.

【Math Figure 10】

$$for \begin{cases} N'_{xBLOCK_TI_MAX} = N_{xBLOCK_TI_MAX} + 1, & \text{if } N_{xBLOCK_TI_MAX} \bmod 2 = 0 \\ N'_{xBLOCK_TI_MAX} = N_{xBLOCK_TI_MAX}, & \text{if } N_{xBLOCK_TI_MAX} \bmod 2 = 1 \end{cases}$$

$$S_{shift} = \frac{N'_{xBLOCK_TI_MAX} - 1}{2}$$

As a result, the cell positions to be read are calculated by a coordinate as $z_{n,s,i} = N_r C_{n,s,i} + R_{n,s,i}$.

FIG. 27 illustrates an operation of a twisted row-column block interleaver according to another embodiment of the present invention.

More specifically, FIG. 27 illustrates the interleaving array in the TI memory for each TI group, including virtual XFECBLOCKs when $N_{xBLOCK_TI}(0,0) = 3$, $N_{xBLOCK_TI}(1,0) = 6$, $N_{xBLOCK_TI}(2,0) = 5$.

The variable number $N_{xBLOCK_TI}(n,s) = N_r$ will be less than or equal to $N'_{xBLOCK_TI_MAX}$. Thus, in order to achieve a single-memory deinterleaving at the receiver side, regardless of $N_{xBLOCK_TI}(n,s)$, the interleaving array for use in a twisted row-column block interleaver is set to the size of $N_r \times N_c = N_{cells} \times N'_{xBLOCK_TI_MAX}$ by inserting the virtual XFECBLOCKs into the TI memory and the reading process is accomplished as follow expression.

【Math Figure 11】

```

p = 0;
for i = 0; i < N_cells * N'_{xBLOCK\_TI\_MAX}; i = i + 1
{GENERATE(R_{n,s,i}, C_{n,s,i});
V_i = N_r C_{n,s,i} + R_{n,s,i}
if V_i < N_{cells} * N_{xBLOCK\_TI}(n,s)
{
Z_{n,s,p} = V_i; p = p + 1;
}
}

```

The number of TI groups is set to 3. The option of time interleaver is signaled in the PLS2-STAT data by DP_TI_TYPE='0', DP_FRAME_INTERVAL='1', and DP_TI_LENGTH='1', i.e., $N_{TI}=1$, $I_{JUMP}=1$, and $P_I=1$. The number of XFECBLOCKs, each of which has $N_{cells} = 30$ cells, per TI group is signaled in the PLS2-DYN data by $N_{xBLOCK_TI}(0,0)=3$, $N_{xBLOCK_TI}(1,0)=6$, and $N_{xBLOCK_TI}(2,0)=5$, respectively. The maximum number of XFECBLOCK is signaled in the PLS2-STAT data by $N_{xBLOCK_Group_MAX}$, which leads to

$$\lfloor N_{xBLOCK_Group_MAX} / N_{TI} \rfloor = N_{xBLOCK_TI_MAX} = 6$$

FIG. 28 illustrates a diagonal-wise reading pattern of a twisted row-column block interleaver according to an embodiment of the present invention.

More specifically FIG. 28 shows a diagonal-wise reading pattern from each interleaving array with parameters of $N'_{xBLOCK_TI_MAX}=7$ and $S_{shift}=(7-1)/2=3$. Note that in the reading process shown as pseudocode above, if $V_i \geq N_{cells} N_{xBLOCK_TI}(n, s)$, the value of V_i is skipped and the next calculated value of V_i is used.

FIG. 29 illustrates interleaved XFECBLOCKs from each interleaving array according to an embodiment of the present invention.

FIG. 29 illustrates the interleaved XFECBLOCKs from each interleaving array with parameters of $N'_{xBLOCK_TI_MAX}=7$ and $S_{shift}=3$.

FIG. 30 is a view illustrating a coding & modulation module according to another embodiment of the present invention.

As described above, a constellation mapper allocates input bit words to one constellation. In this case, a rotation & Q-delay block may be additionally used. The rotation & Q-delay block may rotate input constellations based on rotation angles, divide the same into in-phase (I) components and quadrature-phase (Q) components, and then delay only the Q components by an arbitrary value. After that, newly paired I components and Q components are remapped to new constellations. The constellation mapper and the rotation & Q-delay block may be omitted or may be replaced by other blocks having the same or similar functions.

As described above, a cell interleaver randomly mixes and outputs cells corresponding to one FEC block in such a manner that the cells corresponding to each FEC block are output in a different order from cells corresponding to another FEC block. The cell interleaver may be omitted or may be replaced by another block having the same or similar function.

In the coding & modulation module according to another embodiment of the present invention, the shaded blocks are modified from the above-described coding & modulation module.

The coding & modulation module according to another embodiment of the present invention may

perform periodic-random I/Q interleaving. The periodic-random I/Q interleaving technology may correspond to operations of the Q-delay block and the cell interleaver in this figure. In addition, according to an embodiment, when cell interleaving is omitted, periodic-random I/Q interleaving may be performed before time interleaving. Furthermore, according to another embodiment, when the cell interleaver is omitted, a time interleaver may perform periodic-random I/Q interleaving. In this case, the time interleaver may perform only the periodic-random I/Q interleaving operation, or perform the periodic-random I/Q interleaving operation and the above-described operation of the time interleaver in the next-generation broadcast system.

Overall, periodic-random I/Q interleaving may divide input constellations rotated based on rotation angles into I components and Q components, delay only the Q components by an arbitrary value, and then periodically and randomly mix the components. Periodic-random I/Q interleaving may be performed by one block differently from the above block diagram. In addition, as described above, periodic-random I/Q interleaving may be a technology performed by the time interleaver according to an embodiment. A detailed description of the operation principle of periodic-random I/Q interleaving will be given later.

FIG. 31 is a view illustrating a periodic-random I/Q interleaving technology according to an embodiment of the present invention.

This figure illustrates, as described above, an embodiment in which the constellation mapper and the cell interleaver are replaced by a Q1/Q2-delay block and the above-described periodic-random I/Q interleaver. Here, the periodic-random I/Q interleaving technology may be a concept including the Q1/Q2-delay block and the periodic-random I/Q interleaver. In the following description, the periodic-random I/Q interleaver may refer to only the periodic-random I/Q interleaver of this figure, or refer to the whole periodic-random I/Q interleaving technology including the Q1/Q2-delay block. The first block diagram illustrates an embodiment replaced in single-input and single-output (SISO) mode, and the second block diagram illustrates an embodiment replaced in multiple-input and multiple-output (MIMO) mode.

The Q1/Q2-delay block may divide I components and Q components and then delay only Q components. A delay value in this case may be determined based on use of 2D-SSD and use of 4D-SSD. The Q1-delay block may be used in the case of 2D-SSD, and the Q2-delay block may be used in the case of 4D-SSD.

The periodic-random I/Q interleaver may periodically write and randomly read output of the Q1/Q2-delay block in and from memory. A period used in this case may be determined based on use of 2D-SSD and use of 4D-SSD.

FIG. 32 is a view illustrating a Q1-delay process in the case of 2D-SSD, according to an embodiment of the present invention.

A description is now given of an operation process of a periodic-random I/Q interleaving technology including the Q1-delay block and the periodic-random I/Q interleaver in consideration of 2D-SSD. Here, the size of memory and the number of input cells are assumed as N.

When 2D-SSD is considered, the Q1-delay block may delay the Q components by one cell, and then an output signal thereof may be input to the periodic-random I/Q interleaver. In the figure illustrating the Q1-delay process according to an embodiment of the present invention, it is shown that the I components are constantly maintained and only the Q components are delayed by one cell. Since cyclic shifting is performed, an $(N-1)^{\text{th}}$ Q component is paired with a 0^{th} I component.

FIG. 33 is a view illustrating operation of the periodic-random I/Q interleaver in the case of 2D-SSD, according to an embodiment of the present invention.

When 2D-SSD is considered, the output signal of the Q1-delay block is input to the memory and an input period in this case may be set to 2 to separate neighboring I/Q components of 2D-SSD as far as possible. As such, 0^{th} , 2^{nd} , 4^{th} , ..., $(N-2)^{\text{th}}$ cells may be written in the memory, and then 1^{st} , 3^{rd} , 5^{th} , ..., $(N-1)^{\text{th}}$ cells may be written in the memory. Consequently, this writing process relates to an operation for improving periodicity of the interleaver.

After that, the random interleaver may read the signal stored in the memory and thus the interleaved signal may be ultimately output. The reading process in this case may be performed based on an output index of the random interleaver. The size of the random interleaver may be $N/2$, or the size of an index generated by the random interleaver may be $N/2$. Accordingly, 2 random interleavers may be necessary for the reading process. The output memory index of the random interleaver may be generated using a quadratic polynomial (QP) algorithm or a pseudo-random binary sequence (PRBS) generator. In addition, the same random interleaver may be used for 2 periods in consideration of a writing period, and thus the principle of the writing process for spreading neighboring I/Q components as far as possible may be constantly maintained.

The above-described writing process may be expressed as given by the following equation.

[Equation 12]

$$\pi_w(k) = \frac{N}{2} \bmod(k, 2) + \left\lfloor \frac{k}{2} \right\rfloor, \quad 0 \leq k \leq N-1$$

N : total cell number

$\lfloor \cdot \rfloor$: floor operation

mod : modulus operation

$\pi_w(k)$: writing memory – index for the k^{th} cell

In addition, the above-described reading process may be expressed as given by the following equation.

[Equation 13]

$$\pi_r(k') = \left(\gamma + g \times \frac{k(k+1)}{2} \right) \bmod \frac{N}{2} \text{ for } k' = 0, \dots, 2^n, \text{ where } \lceil \log_2(N/4) \rceil < n \leq \lceil \log_2(N/2) \rceil$$

$$\text{if } 0 \leq \pi_r(k') \leq \frac{N}{2} - 1, \quad \pi_r(k) = \frac{N}{2} g + \pi_r(k') \text{ for } k = 0, \dots, \frac{N}{2} - 1, g = 0, 1$$

N : total cell number

$\lceil \cdot \rceil$: ceil operation

mod : modulus operation

γ : an offset value of a quadratic polynomial (QP)

g : reading period, i.e., $g = 2$ in the case of 2D – SSD

$\pi_r(k')$: output value of QP for the k' order

$\pi_r(k)$: reading memory – index for the k^{th} cell

As shown in the above equations, the writing process improves spreading property of the interleaver while the reading process improves randomness property of the interleaver.

The random interleaving process generates the memory index using, for example, a QP algorithm. In this case, when the generated index is greater than $N/2-1$, the index may not be used as a memory index value but may be discarded, and the QP algorithm may be executed once again. If the re-generated index is less than $N/2-1$, the index may be used as a memory index value to perform the reading process. Here, the QP algorithm may be replaced by an arbitrary random interleaver such as PRBS.

FIG. 34 is a view illustrating operation of the periodic-random I/Q interleaving technology in the case of 2D-SSD when N is 24, according to an embodiment of the present invention.

Even when $N=24$, periodic-random I/Q interleaving operates as described above. Q components are delayed by one cell through the Q1-delay block, a memory writing process is performed based on an

input period of 2, and a memory reading process is performed, thereby performing random interleaving.

The effect of the periodic-random I/Q interleaving technology may be shown using the example of the case in which $N=24$. When an output signal is compared to an input signal, it is shown that the periodic-random I/Q interleaving technology includes both spreading and randomness properties.

FIG. 35 is a view illustrating a Q2-delay process in the case of 4D-SSD, according to an embodiment of the present invention.

A description is now given of an operation process of a periodic-random I/Q interleaving technology including the Q2-delay block and the periodic-random I/Q interleaver in consideration of 4D-SSD. Here, the size of memory and the number of input cells are assumed as N .

When 4D-SSD is considered, the Q2-delay block may delay the Q components by two cells, and then an output signal thereof may be input to the periodic-random I/Q interleaver. In the figure illustrating the Q2-delay process according to an embodiment of the present invention, it is shown that the I components are constantly maintained and only the Q components are delayed by two cells. Since cyclic shifting is performed, $(N-2)^{\text{th}}$ and $(N-1)^{\text{th}}$ Q components are paired with 0^{th} and 1^{st} I components.

FIG. 36 is a view illustrating operation of the periodic-random I/Q interleaver in the case of 4D-SSD, according to an embodiment of the present invention.

When 4D-SSD is considered, the output signal of the Q2-delay block is input to the memory and an input period in this case may be set to 4 to separate I/Q components of two neighboring cells of 4D-SSD as far as possible. As such, 0^{th} , 4^{th} , 8^{th} , ..., $(N-4)^{\text{th}}$ cells may be written in the memory, and then 1^{st} , 5^{th} , 9^{th} , ..., $(N-3)^{\text{th}}$ cells, 2^{nd} , 6^{th} , 10^{th} , ..., $(N-2)^{\text{th}}$ cells, and 3^{rd} , 7^{th} , 11^{th} , ..., $(N-1)^{\text{th}}$ cells may be written in the memory. Consequently, this writing process relates to an operation for improving periodicity of the interleaver.

After that, the random interleaver may read the signal stored in the memory and thus the interleaved signal may be ultimately output. The reading process in this case may be performed based on an output index of the random interleaver. The size of the random interleaver may be $N/4$, or the size of an index generated by the random interleaver may be $N/4$. Accordingly, 4 random interleavers may be necessary for the reading process. The output memory index of the random interleaver may be generated using a quadratic polynomial (QP) algorithm or a pseudo-random binary sequence (PRBS) generator. In addition, the same random interleaver may be used for 4 periods in consideration of a writing period, and thus

the principle of the writing process for spreading I/Q components of two neighboring cells as far as possible may be constantly maintained.

The above-described writing process may be expressed as given by the following equation.

[Equation 14]

$$\pi_w(k) = \frac{N}{4} \bmod(k, 2) + \left\lfloor \frac{k}{4} \right\rfloor, \quad 0 \leq k \leq N - 1$$

N : total cell number

$\left\lfloor \cdot \right\rfloor$: floor operation

mod : modulus operation

$\pi_w(k)$: writing memory – index for the k^{th} cell

In addition, the above-described reading process may be expressed as given by the following equation.

[Equation 15]

$$\pi_r(k') = \left(\gamma + g \times \frac{k(k+1)}{2} \right) \bmod \frac{N}{4} \text{ for } k' = 0, \dots, 2^n, \text{ where } \lceil \log_2(N/8) \rceil < n \leq \lceil \log_2(N/4) \rceil$$

$$\text{if } 0 \leq \pi_r(k') \leq \frac{N}{4} - 1, \quad \pi_r(k) = \frac{N}{4} g + \pi_r(k') \text{ for } k = 0, \dots, \frac{N}{4} - 1, g = 0, 1, 2, 3$$

N : total cell number

$\lceil \cdot \rceil$: ceil operation

mod : modulus operation

γ : an offset value t of a quadratic polynomial (QP)

g : reading period, i.e., $g = 4$ in the case of 4D – SSD

$\pi_r(k')$: output value of QP for the k' order

$\pi_r(k)$: reading memory – index for the k^{th} cell

As shown in the above equations, the writing process improves spreading property of the interleaver while the reading process improves randomness property of the interleaver.

The random interleaving process generates the memory index using, for example, a QP algorithm. In this case, when the generated index is greater than $N/4-1$, the index may not be used as a memory index value but may be discarded, and the QP algorithm may be executed once again. If the re-generated

index is less than $N/4-1$, the index may be used as a memory index value to perform the reading process. Here, the QP algorithm may be replaced by an arbitrary random interleaver such as PRBS.

FIG. 37 is a view illustrating operation of the periodic-random I/Q interleaving technology in the case of 4D-SSD when N is 24, according to an embodiment of the present invention.

Even when $N=24$, periodic-random I/Q interleaving operates as described above. Q components are delayed by two cells through the Q2-delay block, a memory writing process is performed based on an input period of 4, and a memory reading process is performed, thereby performing random interleaving.

The effect of the periodic-random I/Q interleaving technology may be shown using the example of the case in which $N=24$. When an output signal is compared to an input signal, it is shown that the periodic-random I/Q interleaving technology includes both spreading and randomness properties.

FIG. 38 is a detailed block diagram of a demapping & decoding module according to another embodiment of the present invention.

As described above, a cell deinterleaver may deinterleave cells spread within one FEC block, to original positions thereof. The cell deinterleaver performs an inverse operation of the operation of the cell interleaver of the transmitter. In addition, an I-delay block of a constellation demapper delays I components to restore Q components delayed by the transmitter, to original positions thereof.

In the demapping & decoding module according to another embodiment of the present invention, the shaded blocks are modified from the above-described demapping & decoding module.

The demapping & decoding module according to another embodiment of the present invention may include a periodic-random I/Q deinterleaving process. The periodic-random I/Q deinterleaving technology may correspond to operations of the cell deinterleaver and the I-delay block in this figure. In addition, according to an embodiment, when cell deinterleaving is omitted, periodic-random I/Q deinterleaving may be performed after time deinterleaving. Furthermore, according to another embodiment, when the cell deinterleaver is omitted, a time deinterleaver may perform periodic-random I/Q deinterleaving. In this case, the time deinterleaver may perform only the periodic-random I/Q deinterleaving operation, or perform the periodic-random I/Q deinterleaving operation and the above-described operation of the time deinterleaver in the next-generation broadcast system.

FIG. 39 is a view illustrating a periodic-random I/Q deinterleaving technology according to an

embodiment of the present invention.

This figure illustrates, as described above, an embodiment in which the constellation demapper and the cell deinterleaver are replaced by the above-described periodic-random I/Q deinterleaver and an I1/I2 delay block. Here, the periodic-random I/Q deinterleaving technology may be a concept including the periodic-random I/Q deinterleaver and the I1/I2-delay block. In the following description, the periodic-random I/Q deinterleaver may refer to only the periodic-random I/Q deinterleaver of this figure, or refer to the whole periodic-random I/Q deinterleaving technology including the I1/I2-delay block. The first block diagram illustrates an embodiment replaced in single-input and single-output (SISO) mode, and the second block diagram illustrates an embodiment replaced in multiple-input and multiple-output (MIMO) mode.

An overall operation process of the receiver may follow an inverse (restoration) process compared to the operation of the transmitter. The periodic-random I/Q deinterleaving technology corresponding to the invented periodic-random I/Q interleaving technology may be as described below.

The periodic-random I/Q deinterleaver randomly performs writing operation in an opposite direction to the periodic-random I/Q interleaver of the transmitter, and then periodically performs reading operation. A mathematical expression or algorithm used in this case may be the same as that used by the transmitter.

Output of the periodic-random I/Q deinterleaver is input to the I1/I2-delay block. The I1/I2-delay divides I components and Q components and then delays only the I components. A delay value in this case may be determined to 1 and 2 based on use of 2D-SSD and use of 4D-SSD. The I1-delay block may be used in the case of 2D-SSD, and the I2-delay block may be used in the case of 4D-SSD. Consequently, the influence of the Q1/Q2-delay block operating in the transmitter may be offset by the I1/I2- delay.

FIG. 40 illustrates a part of a broadcast signal transmitter for next-generation broadcast service according to another embodiment of the present invention.

Here, a bit interleaved coded modulation (BICM) encoder may correspond to the above-described coding & modulation module. In the current embodiment, the BICM encoder may include an FEC encoder, a bit interleaver, and/or a constellation mapper. According to an embodiment, the BICM encoder may further include a time interleaver. According to an embodiment, the time interleaver may be located after the constellation mapper.

Here, a framing & interleaving module may be a new concept including the above-described frame builder and/or frequency interleaver. The framing & interleaving module according to the current embodiment may include the time interleaver, the frame builder and/or the frequency interleaver. According to an embodiment, the framing & interleaving module may not include the time interleaver. According to an embodiment, the time interleaver may not be included in the BICM encoder or the framing & interleaving module but may be located between the BICM encoder and the framing & interleaving module.

The time interleaver according to an embodiment of the present invention may further include a cell interleaver, a block interleaver, and/or a convolutional interleaver. Here, the cell interleaver may be the above-described cell interleaver. When the cell interleaver is included in the time interleaver, before time interleaving, the cell interleaver may interleave cells in FEC blocks in such a manner that the cells of each FEC block are output in a different order from cells of another FEC block. The block interleaver may perform block interleaving on TI blocks each including one or more FEC blocks. The block interleaver may perform interleaving by linearly writing cells or cell pairs in an FEC block in a column-wise direction, and reading the same in a diagonal-wise direction. In the writing operation, a left part of memory may be filled with virtual FEC blocks and a right part of the memory may be filled with FEC blocks having actual data. In the reading operation, cells or cell pairs of these virtual FEC blocks may not be read but may be skipped. The convolutional interleaver may perform interleaving by spreading the block-interleaved TI blocks to a plurality of signal frames.

The present invention proposes another embodiment of the above-described cell interleaver. The cell interleaver according to another embodiment of the present invention may interleave cells in one FEC block. Due to operation of the cell interleaver, time diversity performance of the time interleaver may be greatly improved. That is, the cell interleaver may improve time diversity of a burst channel environment in association with the time interleaver. In addition, the present invention proposes a cell deinterleaver corresponding to the cell interleaver according to another embodiment of the present invention. Cell interleaving proposed by the present invention may be performed to reduce or eliminate memory used for cell deinterleaving.

The cell interleaver according to another embodiment of the present invention may randomly interleave cells in one FEC block. Such random cell interleaving may be performed through linear writing and random reading using an interleaving pattern.

Initially, the cell interleaver may linearly write cells of an FEC block in the memory (linear writing). Here, the linearly writing operation may refer to an operation for sequentially writing the cells in the memory by the cell interleaver.

After that, the cell interleaver may randomly read the cells linearly written in the memory (random reading). This random reading operation may be performed using an interleaving pattern. Here, the interleaving pattern may be called an interleaving sequence, permutation sequence, interleaving seed, permutation function, memory address, random sequence, or the like.

The cell interleaver may change the permutation sequence used for the random reading operation, every FEC block. Alternatively, according to an embodiment, the permutation sequence may be changed every pair of FEC blocks. As the permutation sequence is changed every FEC block, randomness property of the cell interleaver may be improved.

Here, the permutation sequences for the FEC blocks may be generated by shifting one basic permutation sequence. In this case, the basic permutation sequence may be a pseudo-random sequence.

When only one PLP is present (S-PLP), the above-described time interleaver may not include the cell interleaver. When only one PLP is present, cell interleaving may not be performed.

The cell deinterleaver according to another embodiment of the present invention may be a module of the receiver corresponding to the above-described cell interleaver. The cell deinterleaver according to another embodiment of the present invention may perform an inverse operation of the operation of the above-described cell interleaver.

According to an embodiment, this cell deinterleaver may have a ping-pong structure. In this case, the cell deinterleaver may use memory of an FEC decoder instead of using additional memory for the ping-pong structure. Accordingly, the receiver may not need additional memory for the cell deinterleaver even when the cell deinterleaver has a ping-pong structure. This efficient use of memory is enabled because the above-described cell interleaver has interleaved the cells through linear writing & random reading operation. A detailed description of cell deinterleaving operation will be given below.

FIG. 41 is a view illustrating a basic switch structure according to an embodiment of the present invention.

As described above, according to an embodiment, a cell interleaver may have a ping-pong structure. A demux may send FEC blocks to specific memory banks based on whether the FEC blocks are odd-

numbered or even-numbered. The even-numbered FEC blocks may be sent to memory bank A, and the odd-numbered FEC blocks may be sent to memory bank B. The sent FEC blocks may be cell-interleaved and then sent to a mux. The mux may align and output the received interleaved FEC blocks.

Here, mod may denote modulo operation, and j may have an integer value between 0 and $N_{\text{FEC_block}}-1$. In this case, $N_{\text{FEC_block}}-1$ may denote the number of FEC blocks in an interleaving unit.

FIG. 42 is a view mathematically expressing linear writing & random reading operation of the cell interleaver according to another embodiment of the present invention.

Equation t42010 of the figure shows an input vector of the cell interleaver. X_j may be an input vector of a j^{th} FEC block. $X_j(p)$ values included in X_j may individually indicate cells of the j^{th} FEC block. Here, p may have a value from 0 to $N_{\text{cells}}-1$. In this case, N_{cells} may denote the number of cells in the FEC block.

Equation t42020 of the figure shows an output vector, i.e., an interleaved vector, of the cell interleaver. F_j may be an output vector of the j^{th} FEC block. $F_j(p)$ values included in F_j may individually indicate interleaved cells of the j^{th} FEC block. Here, p may have a value from 0 to N_{cells} . That is, the cells of the input vector X_j may be interleaved by the cell interleaver and thus the order thereof may be changed into the form of F_j .

Equation t42030 of the figure may be a mathematical expression of linear writing & random reading operation of the cell interleaver. Due to the linear writing & random reading operation, the order of the cells of the input FEC block may be changed as indicated by the value of a permutation sequence. In the illustrated equation, the order of a k^{th} cell $F_j(k)$ of the output vector may be changed to be the same as the order of a $C_j(k)^{\text{th}}$ cell $X_j(C_j(k))$ of the input vector. That is, the order may be randomly changed in such a manner that the k^{th} cell becomes the $C_j(k)^{\text{th}}$ cell.

Here, $C_j(k)$ is a random value generated by the above-described random generator, and may correspond to the above-described permutation sequence. $C_j(k)$ may be a permutation sequence for the j^{th} FEC block. This permutation sequence may be implemented using an arbitrary PRBS generator. The present invention is generally applicable irrespective of the PRBS generator.

Here, j may have an integer value between 0 and $N_{\text{FEC_block}}-1$. $N_{\text{FEC_block}}-1$ may denote the number of FEC blocks in an interleaving unit. In addition, k may have a value from 0 to $N_{\text{cells}}-1$.

FIG. 43 is a view mathematically expressing a permutation sequence generating method of the cell

interleaver according to another embodiment of the present invention cell interleaver.

As described above, a permutation sequence may be changed every FEC block. These permutation sequences may be generated by differently shifting one basic permutation sequence. This shifting process may be performed using a shift value to be described below.

$T(k)$ may be a basic permutation sequence generated by the above-described random generator. This basic permutation sequence may also be called a main interleaving pattern. This basic permutation sequence may be used by a main cell interleaver. That is, the basic permutation sequence is used to perform cell interleaving on the first FEC block of a TI block.

S_j may be a shift value used for the j^{th} FEC block. S_j may be added to $T(k)$ and thus used to generate different permutation sequences for different FEC blocks. This shift value may be implemented using an arbitrary PRBS generator. That is, the present invention is generally applicable irrespective of the PRBS generator. According to an embodiment, the shift value may be subtracted from $T(k)$ to generate different permutation sequences for different FEC blocks.

After the shift value is reflected in the basic permutation sequence, modulo operation with N_{cells} may be performed. N_{cells} may denote the number of cells in a corresponding FEC block. Due to modulo operation with N_{cells} , constant shifting may be performed on the basic permutation sequence. As such, different permutation sequences may be generated for different FEC blocks.

FIG. 44 illustrates a part of a broadcast signal receiver for next-generation broadcast service including a cell deinterleaver according to another embodiment of the present invention.

The cell deinterleaver according to another embodiment of the present invention may be a block corresponding to the above-described cell interleaver. The cell deinterleaver may perform an inverse operation of the operation of the cell interleaver of the transmitter. The cell deinterleaver may restore cells interleaved in one FEC block to original positions thereof. An algorithm of cell deinterleaving operation may be performed inversely from the algorithm of cell interleaving operation.

That is, the cell deinterleaver may randomly write cells of an FEC block in memory and then linearly read the written cells (random writing & linear reading). The random writing operation may be performed using a permutation sequence. The linear reading operation may refer to an operation for sequentially reading the cells written in the memory.

In addition, the cell deinterleaver according to another embodiment of the present invention may not perform cell deinterleaving on output of a time deinterleaver. Cell deinterleaving may be performed when the output of the time deinterleaver is stored in FEC decoding memory after an additional decoding process, e.g., constellation demapping, is performed thereon. When data is stored in the FEC decoding memory, the data may be stored in consideration of cell deinterleaving using address values generated by an address generator. That is, memory of an FEC decoder may be used for cell deinterleaving. Consequently, the receiver may not need additional memory for cell deinterleaving, and thus efficient data processing operation of the receiver may be enabled.

According to an embodiment, the cell deinterleaver according to another embodiment of the present invention may be located in the time deinterleaver or located after the time deinterleaver.

FIG. 45 is a view illustrating a broadcast signal transmitting method according to an embodiment of the present invention.

The broadcast signal transmitting method according to an embodiment of the present invention may include formatting an input stream into a plurality of PLPs, encoding data of the PLPs, performing time interleaving, mapping the data to one or more signal frames, and/or performing waveform modulating & transmission.

In the current embodiment, initially, an input formatting block may format an input stream into a plurality of PLPs (t45010). Here, the input formatting block may be the above-described input formatting module. The input stream may be a TS, GS, or IP stream as described above. The PLPs may be the above-described DPs.

After that, data of the PLPs may be encoded by an encoder (t45020). Here, the encoding process may be a concept including a series of the above-described operations such as FEC encoding and bit interleaving. The operations included in the encoding process may vary according to an embodiment. According to an embodiment, the encoder may include an FEC encoder, a bit interleaver, and a constellation mapper. According to an embodiment, this encoder may be called a BICM encoder.

The data of the PLPs may be time-interleaved by a time interleaver (t45030). This process may be performed by the above-described time interleaver. According to an embodiment, the time interleaver may be included in the BICM encoder, or located outside the BICM encoder to time-interleave output of the BICM encoder.

As described above, the time interleaver may include a cell interleaver. The cell interleaver may perform cell interleaving on the data of the PLPs by changing the order of cells in one FEC block. The cell interleaving process may be performed before the above-described block interleaving process.

The data of the PLPs may be mapped to frames by a framer (t45040). Here, the framer may correspond to the above-described frame builder, or the cell mapper included therein. The framer may map the PLP data, on which various processes are performed, to one or more signal frames.

Data of the above-described signal frames may be modulated through waveform modulation (t45050). The waveform modulation process is performed by a waveform module. According to an embodiment, the waveform module may also be called an OFDM module. Due to operation of the waveform module, frequency-interleaved data may be modulated, and the modulated data may be transmitted in a broadcast signal (t45050). According to an embodiment, the waveform module may include at least one antenna.

In a broadcast signal transmitting method according to another embodiment of the present invention, the cell interleaver may perform cell interleaving on cells in one FEC block by performing linear writing & random reading operation on memory. The cell interleaver may sequentially write the cells of the FEC block in the memory, and randomly read the cells from the memory using a permutation sequence.

In the broadcast signal transmitting method according to another embodiment of the present invention, the permutation sequence of each FEC block may differ from that of another FEC block. That is, the permutation sequence may be changed based on an FEC block index.

In the broadcast signal transmitting method according to another embodiment of the present invention, the permutation sequences for different FEC blocks may be determined by differently shifting a basic permutation sequence. Here, the basic permutation sequence may include one or more sequences. According to an embodiment, the permutation sequences may be determined by changing the basic permutation sequence using a scheme other than shifting.

In the broadcast signal transmitting method according to another embodiment of the present invention, the permutation sequence may be generated by adding a shifting value to the basic permutation sequence and performing modulo operation with the number of cells (N_{cells}) in the FEC block. Here, the shifting value may differ every FEC block. That is, the shifting value may have the FEC block index as a variable.

In the broadcast signal transmitting method according to another embodiment of the present invention, the basic permutation sequence may be a pseudo-random sequence.

In the broadcast signal transmitting method according to another embodiment of the present invention, the time interleaver may further include a block interleaver and a convolution delay line block. Here, the convolution delay line block may also be called a convolutional interleaver. After cell interleaving, the block interleaver may perform block interleaving. The block interleaving process may be performed by interleaving time interleaving (TI) blocks each including one or more FEC blocks. After block interleaving, the convolution delay line block may perform convolutional interleaving. The convolutional interleaving process may be performed by interleaving the TI blocks.

In the broadcast signal transmitting method according to another embodiment of the present invention, the above-described encoder may include an FEC encoder, a bit interleaver, and/or a constellation mapper. That is, the above-described step for encoding the data of the PLPs may include performing FEC encoding on the PLP data, performing bit interleaving, and/or performing constellation mapping. In the step for performing constellation mapping, the constellation mapper may constellation-map the bit-interleaved data to FEC blocks by mapping the PLP data to constellations.

A description is now given of a broadcast content receiving method according to an embodiment of the present invention. The broadcast content receiving method according to an embodiment of the present invention is not illustrated in any figure.

The broadcast content receiving method according to an embodiment of the present invention may include receiving a broadcast signal and performing waveform demodulating, performing frame parsing by demapping a plurality of PLPs, performing time deinterleaving on data of the PLPs, decoding the data of the PLPs, and/or outputting an output stream by output-processing the data of the PLPs.

In the current embodiment, a waveform module inside/outside the receiver may receive a broadcast signal including one or more signal frames. Here, the waveform module may perform operation corresponding to the above-described waveform module of the transmitter. The waveform module may demodulate data of the signal frames. According to an embodiment, the waveform module may include at least one antenna and/or tuner. According to an embodiment, the waveform module may also be called an OFDM module.

A frame parser may parse the data of the signal frames by demapping a plurality of PLPs. Data of the

PLPs may be demapped from the signal frames. The frame parser may be the above-described cell demapper or frame parser.

A time deinterleaver may perform time deinterleaving on the PLP data. The time deinterleaver may be located inside or outside a BICM decoder. The current embodiment assumes that the time deinterleaver is not included in the BICM decoder.

The time deinterleaver may include a cell deinterleaver as described above. The cell deinterleaver may change the order of cells in one FEC block of the PLPs. As such, the cells in the FEC block may be restored to original positions thereof. According to an embodiment, the cell deinterleaver may be located outside the time deinterleaver.

The PLP data may be decoded by a decoder. This decoder may be called a BICM decoder. The decoder may include a constellation demapper, a bit deinterleaver, and/or an FEC decoder.

An output processing block may perform output processing on the decoded data of the PLPs. As such, the output processing block may output an output stream. Here, the output processing block may correspond to the above-described output processing module.

According to an embodiment, the above-described steps may be omitted or may be replaced by other steps for performing the same or similar operations.

FIG. 46 is a view illustrating a broadcast signal transmitter according to an embodiment of the present invention.

The broadcast signal transmitter according to an embodiment of the present invention may include the above-described input formatting block, the encoder, the time interleaver, the framer, and/or the waveform block. The time interleaver may further include the cell interleaver, the block interleaver, and/or the convolution delay line block. The encoder may further include the FEC encoder, the bit interleaver, and/or the constellation mapper. Descriptions of the blocks and modules are as given above.

The broadcast signal transmitter according to an embodiment of the present invention and the modules/blocks included therein may implement embodiments of the above-described broadcast signal transmitting method according to the present invention.

A description is now given of a broadcast content receiver according to an embodiment of the present invention. This broadcast content receiver is not illustrated in any figure.

The broadcast content receiver according to an embodiment of the present invention may include the above-described waveform block, the frame parser, the time deinterleaver, the decoder, and/or the output processing block. The time deinterleaver may include the convolution delay line block, the block deinterleaver, and/or the cell deinterleaver. The decoder may further include the constellation demapper, the bit deinterleaver, and/or the FEC decoder. Descriptions of the blocks and modules are as given above.

The broadcast signal receiver according to an embodiment of the present invention and the modules/blocks included therein may implement embodiments of the above-described broadcast signal receiving method according to the present invention.

The above-described input formatting block, the encoder, the time interleaver, the framer, the waveform block, the cell interleaver, the block interleaver, the convolution delay line block, the FEC encoder, the bit interleaver, the constellation mapper, the waveform block, the frame parser, the time deinterleaver, the decoder, the output processing block, the convolution delay line block, the block deinterleaver, the cell deinterleaver, the constellation demapper, the bit deinterleaver, and/or the FEC decoder may be processors for executing sequential processes stored in memory, and may be hardware elements located inside/outside the transmitter/receiver according to an embodiment.

According to an embodiment, the above-described modules may be omitted or may be replaced by other modules for performing the same or similar operations.

Although the description of the present invention is explained with reference to each of the accompanying drawings for clarity, it is possible to design new embodiment(s) by merging the embodiments shown in the accompanying drawings with each other. And, if a recording medium readable by a computer, in which programs for executing the embodiments mentioned in the foregoing description are recorded, is designed in necessity of those skilled in the art, it may belong to the scope of the appended claims and their equivalents.

An apparatus and method according to the present invention may be non-limited by the configurations and methods of the embodiments mentioned in the foregoing description. And, the embodiments mentioned in the foregoing description can be configured in a manner of being selectively combined with one another entirely or in part to enable various modifications.

In addition, a method according to the present invention can be implemented with processor-readable codes in a processor-readable recording medium provided to a network device. The processor-readable medium may include all kinds of recording devices capable of storing data readable by a processor. The

processor-readable medium may include one of ROM, RAM, CD-ROM, magnetic tapes, floppy discs, optical data storage devices, and the like for example and also include such a carrier-wave type implementation as a transmission via Internet. Furthermore, as the processor-readable recording medium is distributed to a computer system connected via network, processor-readable codes can be saved and executed according to a distributive system.

It will be appreciated by those skilled in the art that various modifications and variations can be made in the present invention without departing from the spirit or scope of the inventions. Thus, it is intended that the present invention covers the modifications and variations of this invention provided they come within the scope of the appended claims and their equivalents.

Both apparatus and method inventions are mentioned in this specification and descriptions of both of the apparatus and method inventions may be complementarily applicable to each other.

【Mode for Invention】

Various embodiments have been described in the best mode for carrying out the invention.

【Industrial Applicability】

The present invention is available in a series of broadcast signal provision fields.

It will be apparent to those skilled in the art that various modifications and variations can be made in the present invention without departing from the spirit or scope of the inventions. Thus, it is intended that the present invention covers the modifications and variations of this invention provided they come within the scope of the appended claims and their equivalents.

CLAIMS:

1. A method of receiving broadcast signals, the method including:

receiving broadcast signals having at least one signal frame;

demodulating data in the at least one signal frame;

frame parsing the demodulated data in the at least one signal frame by demapping plural Physical Layer Pipes, PLPs;

cell deinterleaving cells of the plural PLPs arranged in Forward Error Correction, FEC, blocks, wherein at least one FEC block is included in a Time Interleaving, TI, block,

wherein the cell deinterleaving includes

writing cells in a FEC block into a memory randomly by using a permutation sequence,

reading the cells from the memory linearly,

wherein the permutation sequence varies each FEC block with a TI block by shifting a basic permutation sequence based on a shift value respectively;

decoding data in the cell deinterleaved cells; and

output formatting the decoded data to output streams.
2. The method of claim 1,

wherein the shift value is different for each FEC block with a TI block.
3. The method of claim 1,

wherein the permutation sequence is generated by adding the shift value to the basic permutation sequence, and by applying modulo operation with a number of cells in a FEC block.
4. The method of claim 1,

wherein the basic permutation sequence is a pseudo random sequence.

5. The method of claim 1,

wherein the method further includes block deinterleaving data in the plural PLPs.

6. The method of claim 5,

wherein the block deinterleaving further includes:

diagonal-wise writing the data in the plural PLPs into at least one Time Interleaving, TI, block,

wherein the at least one TI block includes at least one virtual Forward Error Correction, FEC; and

column-wise reading the at least one TI block,

wherein cells belonging the at least one virtual FEC block are skipped during the diagonal-wise writing.

7. An apparatus for receiving broadcast signals, the apparatus including:

a receiver to receive broadcast signals having at least one signal frame;

a demodulator to demodulate data in the at least one signal frame;

a frame parser to parse the demodulated data in the at least one signal frame by demapping plural Physical Layer Pipes, PLPs;

a cell deinterleaver to cell deinterleave cells of the plural PLPs arranged in Forward Error Correction, FEC, blocks, wherein at least one FEC block is included in a Time Interleaving, TI, block,

wherein the cell deinterleaver performs:

writing cells in a FEC block into a memory randomly by using a permutation sequence,

reading the cells from the memory linearly,

wherein the permutation sequence varies each FEC block with a TI block by shifting a basic permutation sequence based on a shift value respectively;

a decoder to decode data in the cell deinterleaved cells; and

an output formatter to output the decoded data to output streams.

8. The apparatus of claim 7,

wherein the shift value is different for each FEC block with a TI block.

9. The apparatus of claim 7,

wherein the permutation sequence is generated by adding the shift value to the basic permutation sequence, and by applying modulo operation with a number of cells in a FEC block.

10. The apparatus of claim 7,

wherein the basic permutation sequence is a pseudo random sequence.

11. The apparatus of claim 7, wherein the apparatus further includes a block deinterleaver to block deinterleave data in the plural PLPs.

12. The apparatus of claim 11,

wherein the block deinterleaver performs:

diagonal-wise writing the data in the plural PLPs into at least one Time Interleaving, TI, block,

wherein the at least one TI block includes at least one virtual Forward Error Correction, FEC; and

column-wise reading the at least one TI block,

wherein cells belonging the at least one virtual FEC block are skipped during the diagonal-wise writing.
