WO 2013/024047 A1

High-loading water-soluble carrier-linked prodrugs

5 Drugs frequently exhibit short plasma half-life due to renal and receptor-mediated clearance, aggregation, proteolytic degradation, poor bioavailability and physical properties which preclude efficient formulations. This is highly undesirable as it leads to the need for frequent and repeated administration of the drug, resulting in increased costs and inconvenience for the patient.

10

One mechanism for enhancing the availability of drugs is by conjugating them with derivatizing compounds, which include, for example, poly(ethylene glycol) (PEG) and poly(propylene glycol). Some of the benefits recognized include lowered immunogenicity and antigenicity, increased duration of action, and altered pharmacokinetic properties (Veronese, 15 F.M. "Enzymes for Human Therapy: Surface Structure Modifications," *Chimica Oggi*, 7:53-56, 1989).

To enhance physicochemical or pharmacokinetic properties of a drug *in vivo*, drugs can be bound to carriers in a non-covalent way, using physicochemical formulations of drug-solvent-carrier mixtures. However, the non-covalent approach requires a highly efficient drug 20 encapsulation to prevent uncontrolled, burst-type release of the drug. Restraining the diffusion of an unbound, water soluble drug molecule requires strong van der Waals contacts, frequently mediated through hydrophobic moieties. Many conformationally sensitive drugs, such as proteins or peptides, are rendered dysfunctional during the encapsulation process and/or during subsequent storage of the encapsulated drug. In addition, such amino- 25 containing drugs readily undergo side reactions with carrier degradation products. Furthermore, dependence of the release mechanism of the drug upon biodegradation may cause interpatient variability.

30 Alternatively, the drugs may be conjugated to a carrier via a transient linker molecule, resulting in carrier-linked prodrugs. This approach is applied to various classes of molecules, from so-called small molecules, through natural products up to larger peptides and proteins.

Prodrug activation may occur by enzymatic or non-enzymatic cleavage of the bond between the carrier and the drug molecule, or a sequential combination of both, i.e. an enzymatic step followed by a non-enzymatic rearrangement.

5 Enzymatically induced prodrug activation is characterized in that the cleavage in enzyme-free *in vitro* environment such as an aqueous buffer solution, of, e.g., an ester or amide may occur, but the corresponding rate of hydrolysis may be much too slow and not therapeutically useful. In an *in-vivo* environment, esterases or amidases are typically present and the esterases and amidases may cause significant catalytic acceleration of the kinetics of hydrolysis from
10 twofold up to several orders of magnitude. Therefore, the cleavage is predominantly controlled by the enzymatic reaction.

A major drawback of predominantly enzymatic cleavage is interpatient variability. Enzyme levels may differ significantly between individuals resulting in biological variation of prodrug
15 activation by the enzymatic cleavage. The enzyme levels may also vary depending on the site of administration. For instance it is known that in the case of subcutaneous injection, certain areas of the body yield more predictable therapeutic effects than others. To reduce this unpredictable effect, non-enzymatic cleavage or intramolecular catalysis is of particular interest.

20 Therefore, enzyme-independent autocatalytic cleavage of carrier and drug is preferred. In most cases this is achieved by an appropriately designed linker moiety between the carrier and the drug, which is directly attached to a functional group of a drug via covalent bond.

25 A number of such enzyme-independent prodrugs suitable for different classes of biologically active moieties are known in the art. Examples can be found in the international patent applications WO-A 2005/099768, WO-A 2006/13565869, WO-A 2009/095479, and WO-A 2011/012722.

30 Typically, carrier-linked prodrugs have a stoichiometry of one drug molecule conjugated to one carrier moiety. However, for many medical applications such stoichiometry is disadvantageous as large volumes of such conjugates would have to be applied to a patient to ensure a high enough dose of drug, causing undue pain and possibly requiring increased

amounts of time for the administration process and thus increasing the costs of the treatment. In such situations, carrier-linked prodrugs in which more than one drug moiety is conjugated to a carrier molecule might be better suited as they provide a higher drug loading and thus require smaller volumes of the pharmaceutical composition to be administered to a patient.

5

Patent US 7744861 B2 discloses multi-arm prodrugs in which at least three arms extend from a branching core and each of these arms carries one drug moiety. Similarly, WO-A 2010/019233 discloses multi-arm prodrugs of which each arm of a carrier moiety is conjugated to one drug moiety. Despite the multi-arm backbone structure, such carrier-linked prodrugs still have a relatively low drug load.

10

More carrier-linked prodrugs with two polymer-based arms are disclosed in WO-A 2008/034119, wherein each arm is attached to a drug moiety, diagnostic agent or targeting moiety.

15

Prodrugs of the anti-malaria drug artelinic acid are disclosed in US 6461603 B2. The polymeric prodrugs are also based on a backbone moiety from which arms extend which each carry one drug moiety at their terminus.

20

Another approach to high-loading carrier-linked prodrugs involves the use of dendrimers. Dendrimers are repeatedly branched, roughly spherical, large molecules. Dendrimers have been used to non-covalently embed drug moieties and for covalent attachment of drug moieties to the termini of the dendrimer.

25

Taite & West (J. Biomater. Sci. Polymer Edn, 2006, 17, 1159-1172) describe lysine-based dendrimer moieties in which free amines have been converted to diazeniumdiolate NO-donors through the reaction with NO gas. The dendrimers released NO over a period of 60 days. However, this approach does not allow for the adjustment of release speed as no reversible prodrug linkers have been used to attach the NO to the termini of the dendrimer and this approach is also not transferable to other drug moieties.

30

US 2010/0160299 A1 discloses dendrimers to which therapeutic agents for the reduction and/or elimination of pain are connected in a reversible manner. Similarly, WO-A

2010/075423 discloses modular dendrimer platforms suitable for the delivery of therapeutic agents, for example.

However, dendrimers typically exhibit a low degree of water-solubility. When poorly water-soluble drug moieties are coupled to the functional groups of such dendrimers the resulting conjugates are even less water-soluble. Therefore, although dendrimers provide a high drug loading, their applicability for prodrug approaches is limited.

Therefore, there is a need to provide novel water-soluble carrier-linked prodrugs that at least partially overcome the above-mentioned shortcomings. This object is achieved with a water-soluble carrier-linked prodrug of formula (I):

wherein

B, A and Hyp form a carrier moiety, and wherein

B is a branching core,

each A is independently a poly(ethylene glycol)-based polymeric chain,

each Hyp is independently a branched moiety,

each SP is independently a spacer moiety,

each L is independently a reversible prodrug linker moiety,

each D is independently a biologically active moiety,

each x is independently 0 or 1,

each m is independently an integer of from 2 to 64,

n is an integer from 3 to 32;

or a pharmaceutically acceptable salt thereof.

5 It was now surprisingly found that such water-soluble carrier-linked prodrug can be used as a sustained-release dosage form of biologically active moieties with a high drug loading due to the presence of the branched moieties. In addition, the poly(ethylene glycol)-based (PEG-based) polymeric chain allows for increased water-solubility.

10 Within the present invention the terms are used having the meaning as follows.

The terms "drug", "biologically active molecule", "biologically active moiety", "biologically active agent", "active agent", "active substance" and the like mean any substance which can affect any physical or biochemical properties of a biological organism, including but not
15 limited to viruses, bacteria, fungi, plants, animals, and humans. In particular, as used herein, the terms include any substance intended for diagnosis, cure, mitigation, treatment, or prevention of disease in organisms, in particular humans or other animals, or to otherwise enhance physical or mental well-being of organisms, in particular humans or animals.

20 "Biologically active moiety D" means the part of a biologically active moiety-reversible prodrug linker conjugate or the part of a biologically active moiety-reversible prodrug linker-carrier conjugate, which results after cleavage in a drug D-H of known biological activity.

"Amine-containing biologically active moiety" or "hydroxyl-containing biologically active
25 moiety" means the part (moiety or fragment) of a biologically active moiety-reversible prodrug linker conjugate or the part of a biologically active moiety-reversible prodrug linker-carrier conjugate (active agent) of (known) biological activity, and which part of the drug comprises at least one amine or hydroxyl group, respectively.

30 In addition, the subterm "aromatic amine-containing" means that the respective biologically active moiety D and analogously the corresponding drug D-H contains at least one aromatic fragment which is substituted with at least one amino group. The subterm "aliphatic amine-containing" means that the respective biologically active moiety D and analogously the

corresponding drug D-H contains at least one aliphatic fragment which is substituted with at least one amino group. Without further specification the term “amine-containing” is used generically and refers to aliphatic and aromatic amine-containing moieties.

5 The subterm “aromatic hydroxyl-containing” means that the respective moiety D and analogously the corresponding drug D-H contains at least one aromatic fragment, which is substituted with at least one hydroxyl group. The subterm “aliphatic hydroxyl-containing” means that the hydroxyl group of the respective moiety D and analogously the corresponding drug D-H is connected to an aliphatic fragment. Without further specification the term
10 “hydroxyl-containing” is used generically and refers to aliphatic and aromatic hydroxyl-containing moieties.

“Free form” of a drug refers to the drug in its unmodified, pharmacologically active form, such as after being released from a carrier-linked prodrug.

15 Targeting moieties are moieties that when present in a molecule, such as for example in a prodrug, allow preferential localization of such larger molecule in specific target areas of the organism to which it has been administered. Such specific target areas might be organs, certain cell types or subcellular compartments. “Preferential localization” means that at least
20 10%, preferably at least 20% and more preferably at least 30% of the biologically active moieties administered to a patient reach said specific target areas.

Targeting moieties may be divided into 3 classes according to size:

- small molecular targeting moieties, for example C-glucuronide, cobalamin, vitamins
25 such as folic acid (folate) and analogs and derivatives, carbohydrates, bisphosphonates, N-acetylgalactosamine,
- peptides, for example bombesin, somatostatin, LHRH, EGF, VEGF, hCG, fragments of luteinizing hormone (LH), octreotide, vapreotide, lanreotide, RC-3940 series,
30 decapeptyl, lupron, zoladex, cetorelix, peptides or peptidomimetics containing the NGR or RGD motifs or derived from these motifs such as CNGRC (linear), GNGRG (cyclic), ACDC RGD CFCG (cyclic), CDCRGDCFC, CNGRC (cyclic), CRGDCGG, CNGRC, or other peptides such as ATWLPPR, thrombospondin (TSP)-1 mimetics,

(RGD peptidomimetic), CTTHWGFTLC, CGNKRTRGC, neuropeptide substance P, SSP, the Sar9, Met(O2)11 analog of substance P, cholecystokinin (CCK), corticotropin-releasing hormone/factor (CRH/CRF), dermorphin, FGF-2 or basic fibroblast growth factor, galanin, melanopsin, neurotensin,

- 5
- and protein or macro- molecular targeting moieties, for example IL-2, GM-CSF, TNF- α , transferrin, immunoglobulins, acetylated-LDL, lactoferrin (Lf) (also called lactotransferrin) and lactoferricin (Lcin), gambogic acid (GA), antibody fragments and affinity scaffold proteins.

10

In principle, any ligand of a cell surface receptor may be advantageously used as a targeting moiety. For instance, ATWLPPR peptide is a potent antagonist of VEGF; thrombospondin-1 (TSP-1) induces apoptosis in endothelial cells, RGD-motif mimics block integrin receptors, NGR-containing peptides inhibit aminopeptidase N, and cyclic peptides containing the

15

sequence of HWGF selectively inhibit MMP-2 and MMP-9. LyP-1 peptide specifically binds to tumor lymphatic vessels. Illustrative other ligands include peptide ligands identified from library screens, tumor cell-specific peptides, tumor cell-specific aptamers, tumor cell-specific carbohydrates, tumor cell-specific monoclonal or polyclonal antibodies, Fab or scFv (i.e., a single chain variable region) fragments of antibodies such as, for example, a Fab fragment of

20

an antibody directed to EphA2 or other proteins specifically expressed or uniquely accessible on metastatic cancer cells, small organic molecules derived from combinatorial libraries, growth factors, such as EGF, FGF, insulin, and insulin-like growth factors, and homologous polypeptides, somatostatin and its analogs, transferrin, lipoprotein complexes, bile salts, selecting, steroid hormones, Arg-Gly-Asp containing peptides, retinoids, various Galectins, δ -opioid receptor ligands, cholecystokinin A receptor ligands, ligands specific for angiotensin AT1 or AT2 receptors, peroxisome proliferator-activated receptor λ ligands, β -lactam antibiotics such as penicillin, small organic molecules including antimicrobial drugs, and other molecules that bind specifically to a receptor preferentially expressed on the surface of

25

tumor cells or on an infectious organism, antimicrobial and other drugs designed to fit into the binding pocket of a particular receptor based on the crystal structure of the receptor or other

30

cell surface protein, ligands of tumor antigens or other molecules preferentially expressed on the surface of tumor cells, or fragments of any of these molecules. Examples of tumor-specific antigens that can function as targeting moieties include extracellular epitopes of a member of

the ephrin family of proteins, such as EphA2. EphA2 expression is restricted to cell-cell junctions in normal cells, but EphA2 is distributed over the entire cell surface in metastatic tumor cells. Thus, EphA2 on metastatic cells would be accessible for binding to, for example, a Fab fragment of an antibody conjugated to an immunogen, whereas the protein would not be accessible for binding to the Fab fragment on normal cells, resulting in a targeting moiety specific for metastatic cancer cells.

Further examples for such targeting moieties are: FSH-33, allatostatin 1, hepatocarcinoma targeting peptide, peptide GFE, anti-EGFR antibodies and/or antibody fragments, in particular cetuximab, CendR, iRGD peptide (RGD-CendR hybrid peptide), small molecules, antibodies and/or antibody fragments binding to cancer-specific epitopes like e.g. CEA, gastrin-releasing peptide receptors, somatostatin receptors, galanin receptors, follicle-stimulating hormone receptors, p32 protein, fibroblast growth factor receptors, HepG2, epidermal growth factor receptors, integrin $\alpha v \beta 6$, neuropilin-1 receptor and VEGF receptors.

The phrases “in bound form”, “connected to”, and “moiety” refer to sub-structures which are part of a molecule. The phrases “in bound form” or “connected to” are used to simplify reference to moieties or functional groups by naming or listing reagents, starting materials or hypothetical starting materials well known in the art, and whereby “in bound form” and “connected to” means that for example one or more hydrogen radicals ($-H$) or one or more activating or protecting groups present in the reagents or starting materials are not present in the moiety when part of a molecule.

To enhance physicochemical or pharmacokinetic properties of a drug *in vivo*, such drug can be conjugated with a carrier, as in the present invention. If the drug is transiently bound to a carrier and/or a linker, as in the present invention, such systems are commonly assigned as “carrier-linked prodrugs”. According to the definitions provided by IUPAC (as given under <http://www.chem.qmul.ac.uk/iupac/medchem/ah.html>, accessed on March 7, 2011), a carrier-linked prodrug is a prodrug that contains a temporary linkage of a given active substance with a transient carrier group that produces improved physicochemical or pharmacokinetic properties and that can be easily removed *in vivo*, usually by a hydrolytic cleavage.

The term “promoiety” refers to the part of the prodrug which is not the drug, thus meaning linker(s), carrier(s) and/or any optional spacer moiety/moieties.

The terms “reversible prodrug linker” or “transient prodrug linker” refer to linker that are non-enzymatically hydrolytically degradable, i.e. cleavable, under physiological conditions (aqueous buffer at pH 7.4, 37°C) with half-lives ranging from, for example, one hour to three months. On the other hand, stable or permanent linkers have stable or permanent linkages, which are typically non-cleavable permanent bonds, meaning that they have a half-life of at least six months under physiological conditions (aqueous buffer at pH 7.4, 37°C).

A “traceless prodrug linker” refers to a prodrug linker from which a drug is released in its free form, meaning that upon release from the promoiety the drug does not contain any traces of the promoiety.

“Non-biologically active linker” means a linker which does not show the pharmacological effects of the drug (D-H) derived from the biologically active moiety.

The term “polymer” describes a molecule comprising, in particular consisting of, repeating structural units connected by chemical bonds in a linear, circular, branched, crosslinked or dendrimeric way or a combination thereof, which can be of synthetic or biological origin or a combination of both. It is understood, that e.g. capping moieties may be present in a polymer.

The term “polymeric” refers to a moiety comprising one or more polymer.

The term “poly(ethylene glycol)-based polymeric chain” or “PEG-based polymeric chain” refers to a polymer chain comprising at least 10% by weight, preferably at least 25%, more preferably at least 50% by weight, even more preferably at least 80% by weight poly(ethylene glycol). It is understood that a PEG-based polymeric chain may be terminated in case of branched chains and/or interrupted by alkyl or aryl groups and optionally be substituted with heteroatoms and/or functional groups.

The terms “spacer”, “spacer group”, “spacer molecule”, and “spacer moiety” are used interchangeably and refer to any moiety suitable for connecting two moieties, such as C₁₋₅₀

alkyl, C₂₋₅₀ alkenyl or C₂₋₅₀ alkynyl, which moiety is optionally interrupted by one or more groups selected from -NH-, -N(C₁₋₄ alkyl)-, -O-, -S-, -C(O)-, -C(O)NH-, -C(O)N(C₁₋₄ alkyl)-, -O-C(O)-, -S(O)-, -S(O)₂-, 4- to 7-membered heterocyclyl, phenyl and naphthyl.

- 5 The term “terminus” refers to the last carbon atom or heteroatom of a linear or branched chain comprising, in particular consisting of carbon atoms or heteroatoms, i.e. to a carbon or heteroatom which is connected to exactly one other carbon or heteroatom.

The term “branched moiety” refers to a moiety comprising at least one branching point. Such
10 branching point comprises, for example, an at least 3-fold substituted carbocycle, an at least 3-fold substituted heterocycle, a tertiary carbon atom, a quaternary carbon atom or a tertiary nitrogen atom.

A carbocycle and heterocycle may be substituted by C₁₋₂₀ alkyl, optionally interrupted or
15 terminated by heteroatoms or functional groups selected from the group consisting of -O-, -S-, N(R), C(O), C(O)N(R), and N(R)C(O), wherein R is hydrogen or a C₁₋₁₀ alkyl chain, which is optionally interrupted or terminated by one or more of the above mentioned atoms or groups which further have a hydrogen as terminal atom.

20 "Pharmaceutical composition" or “composition” means a composition comprising one or more drugs or prodrugs, and optionally one or more pharmaceutically acceptable excipients, as well as any product which results, directly or indirectly, from combination, complexation or aggregation of any two or more of the ingredients, or from dissociation of one or more of the pharmaceutically acceptable excipients, or from other types of reactions or interactions of
25 one or more of the pharmaceutically acceptable excipients. Accordingly, the pharmaceutical compositions of the present invention encompass any composition obtainable by admixing a water-soluble carrier-linked prodrug of the present invention and optionally one or more pharmaceutically acceptable excipients.

30 The term "excipient" refers to a diluent, adjuvant, or vehicle with which the water-soluble carrier-linked prodrug is administered. Such pharmaceutical excipient can be sterile liquids, such as water and oils, including those of petroleum, animal, vegetable or synthetic origin, including but not limited to peanut oil, soybean oil, mineral oil, sesame oil and the like. Water

is a preferred excipient when the pharmaceutical composition is administered orally. Saline and aqueous dextrose are preferred excipients when the pharmaceutical composition is administered intravenously. Saline solutions and aqueous dextrose and glycerol solutions are preferably employed as liquid excipients for injectable solutions. Suitable pharmaceutical excipients include starch, glucose, lactose, sucrose, mannitol, trehalose, gelatin, malt, rice, flour, chalk, silica gel, sodium stearate, glycerol monostearate, talc, sodium chloride, dried skim milk, glycerol, propylene, glycol, water, ethanol and the like. The composition, if desired, can also contain minor amounts of wetting or emulsifying agents, pH buffering agents, like, for example, acetate, succinate, tris, carbonate, phosphate, HEPES (4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid), MES (2-(*N*-morpholino)ethanesulfonic acid), or can contain detergents, like Tween, poloxamers, poloxamines, CHAPS, Igepal, or amino acids like, for example, glycine, lysine, or histidine. These compositions can take the form of solutions, suspensions, emulsions, tablets, pills, capsules, powders, sustained-release formulations and the like. The composition can be formulated as a suppository, with traditional binders and excipients such as triglycerides. Oral formulation can include standard excipients such as pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, etc. Examples of suitable pharmaceutical excipients are described in "Remington's Pharmaceutical Sciences" by E.W. Martin. Such compositions will contain a diagnostically and/or therapeutically effective amount of the a water-soluble carrier-linked prodrug, preferably in purified form, together with a suitable amount of excipient so as to provide the form for proper administration to the patient. The formulation should suit the mode of administration.

The term "pharmaceutically acceptable" means approved by a regulatory agency such as the EMEA (Europe) and/or the FDA (US) and/or any other national regulatory agency for use in animals, preferably in humans.

"Dry composition" means that the pharmaceutical composition comprising water-soluble carrier-linked prodrug according to the present invention is provided in a dry form in a container. Suitable methods for drying are spray-drying and lyophilization (freeze-drying). Such dry composition of water-soluble carrier-linked prodrug has a residual water content of a maximum of 10 %, preferably less than 5% and more preferably less than 2% (determined according to Karl Fischer). The preferred method of drying is lyophilization.

“Lyophilized composition” means that the pharmaceutical composition comprising water-soluble carrier-linked prodrug was first frozen and subsequently subjected to water reduction by means of reduced pressure. This terminology does not exclude additional drying steps which may occur in the manufacturing process prior to filling the composition into the final container.

“Lyophilization” (freeze-drying) is a dehydration process, characterized by freezing a composition and then reducing the surrounding pressure and, optionally, adding heat to allow the frozen water in the composition to sublime directly from the solid phase to gas. Typically, the sublimed water is collected by desublimation.

The term “functional group” refers to a specific group of atoms within molecules that can undergo characteristic chemical reactions. Examples of functional groups are hydroxyl, carbonyl, aldehyde, carboxyl, ester, ketal, hemiketal, acetal, hemiacetal, primary/secondary/tertiary amine, cyanate, disulfide, sulfhydryl, sulfonyl and phosphate groups.

If a functional group is coupled to another functional group, the resulting chemical structure is referred to as “linkage”. For example, the reaction of an amine functional group with a carboxyl functional group results in an amide linkage. Further examples for linkages are ester, ether, ketal, acetal, secondary/tertiary amine, carboxamide, sulfide and disulfide linkages.

“Alkyl” means a straight-chain or branched carbon chain (unsubstituted alkyl). Optionally, one or more hydrogen atoms of an alkyl carbon may be replaced by a substituent. In general, a preferred alkyl is C₁₋₆ alkyl.

“C₁₋₄ alkyl” means an alkyl chain having 1 to 4 carbon atoms (unsubstituted C₁₋₄ alkyl), e.g. if present at the end of a molecule: methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, tert-butyl, or e.g. -CH₂-, -CH₂-CH₂-, -CH(CH₃)-, -CH₂-CH₂-CH₂-, -CH(C₂H₅)-, -C(CH₃)₂-, when two moieties of a molecule are linked by the alkyl group (also referred to as C₁₋₄ alkylene). Optionally, one or more hydrogen atom(s) of a C₁₋₄ alkyl carbon may be replaced by a substituent as indicated herein. Accordingly, “C₁₋₅₀ alkyl” means an alkyl chain having 1 to 50 carbon atoms.

"C₁₋₆ alkyl" means an alkyl chain having 1 - 6 carbon atoms, e.g. if present at the end of a molecule: C₁₋₄ alkyl, methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, tert-butyl, n-pentyl, n-hexyl, or e.g. -CH₂-, -CH₂-CH₂-, -CH(CH₃)-, -C(CH₂)-, -CH₂-CH₂-CH₂-, -CH(C₂H₅)-, -C(CH₃)₂-, when two moieties of a molecule are linked by the alkyl group (also referred to as C₁₋₆ alkylene). One or more hydrogen atom(s) of a C₁₋₆ alkyl carbon may be replaced by a substituent as indicated herein. The terms C₁₋₁₅ alkyl or C₁₋₁₅ alkylene are defined accordingly.

In the following sections preferred embodiments of the present invention are described.

In a preferred embodiment, the carrier of formula (I) comprises a quaternary carbon, in particular a quaternary carbon of a branching core moiety B, wherein B is pentaerythritol in bound form. Preferably, each A is independently a PEG-based polymeric chain terminally
5 attached to the quaternary carbon of pentaerythritol via the $-\text{CH}_2\text{-O}-$ moieties of pentaerythritol by a permanent covalent linkage, and the distal end of each moiety A is covalently bound to a moiety Hyp, each moiety Hyp is conjugated to m moieties L, either directly or indirectly through a moiety SP and which moieties L are each connected to a biologically active moiety D.

10

In one preferred embodiment, a moiety Hyp of formula (I) comprises, preferably consists of, branched polyamines comprising at least 2 amine groups. Preferably, such branched polyamine comprises one or more lysine residues in bound form. Preferably, each Hyp of formula (I) has a molecular weight of from 0.1 kDa to 4 kDa, in particular of from 0.2 to 2
15 kDa. In a preferred embodiment, n is 4 and each of the 4 moieties Hyp may independently consist of the same or different moieties Hyp. In a preferred embodiment, the 4 moieties Hyp are the same.

20

In a preferred embodiment, a moiety Hyp comprises, in particular consists of, between 1 and 32 lysines in bound form, preferably comprises, in particular consists of, 1, 3, 7 or 15 lysines in bound form, more preferably of 1, 3 or 7 lysines in bound form. Most preferably, Hyp comprises, in particular consists of, heptalysinyl.

25

Preferably, the carrier of formula (I) with $n = 4$ has a molecular weight of from 1 kDa to 80 kDa, more preferably of from 1 kDa to 40 kDa and even more preferably of from 10 kDa to 40 kDa.

Preferred carrier moieties of formula (I) are selected from structures (i) to (iii):

4

(iii),

wherein

5 dashed lines indicate attachment to sub-structures $-(SP)_x-L-D$ of formula (I),

p is an integer from 5 to 2000, preferably from 10 to 1000, more preferably from 10 to 500, and even more preferably from 100 to 500,

10 q is 1 or 2.

In a preferred embodiment, B is pentaerythritol.

Another subject of the present invention is a method for the synthesis of the water-soluble
 15 carrier-linked prodrug of formula (I) or a pharmaceutically acceptable salt thereof. Water-

soluble carrier-linked prodrugs of formula (I) or precursors thereof invention may be prepared by known methods or in accordance with the reaction sequences described below. The starting materials used in the preparation (synthesis) of water-soluble carrier-linked prodrugs of formula (I) or precursors thereof are known or commercially available, or can be prepared
5 by known methods or as described below.

A preferred starting material is a 4-arm-PEG amine reagent with the 4-arm-PEG amine reagent having a molecular weight ranging from 0.2 to 160 kDa. To such 4-arm-PEG amine reagent, lysine residues are coupled sequentially to form the carrier. It is understood that the
10 lysines can be partially or fully protected by protective groups during the coupling steps and that also the final carrier may contain protective groups. A preferred building block is bis-boc lysine.

Alternatively, instead of sequential additions of lysine residues, a branched poly-lysine
15 moiety may be assembled first and subsequently coupled to the 4-arm-PEG amine reagent. Such polylysine may be obtained by batch condensation or by means of sequential assembly using protected lysine building blocks.

For example it may be desirable to obtain such carrier carrying 32 amino groups,
20 consequently seven lysines would be attached to each arm of a 4-arm-PEG amine.

In another embodiment, the PEG reagent may be a 4-arm-PEG-carboxylate. In this case the dendritic moieties may be generated from glutamic or aspartic acid, and the resulting carrier would carry a number of terminal carboxy groups.

25 Alternatively, instead of sequential additions of glutamic or aspartic acid residues, a branched poly-glutamate or poly-aspartate moiety may be assembled first and subsequently coupled to the 4-arm-PEG-carboxylate reagent. Such polyglutamate or -aspartate may be obtained by batch condensation or by means of sequential assembly using corresponding protected amino
30 acid building blocks.

In yet another embodiment, an oligo- or polyglycerol may be converted into a corresponding poly-amine comprising a glycerol condensation product core. Such polyglycerol-derived

poly-amine may be coupled to a 4-arm-PEG-carboxylate reagent to yield a suitable carrier. It is understood that carboxy groups may be activated to enhance their reactivity. For instance, the carboxy group may be converted into a chloride or an active ester.

- 5 It is also understood that all or a fraction of the carrier's reactive functional groups may be present in a free form, as salts or conjugated to protecting or activating groups. Due to practical reasons, the carrier reagent's number of branches per arm of the multi-arm, such as a 4-arm PEG reagent will be in a range of, for example 1 to 15, more preferably 1 to 7.
- 10 Functional groups of the carrier are then used for coupling linker reagents comprising suitable complementary functional groups to yield carrier-linker conjugate reagents. To such carrier-linker conjugate reagents are subsequently drugs coupled. Alternatively, a drug moiety may first be coupled to a linker reagent and subsequently, the biologically active moiety-linker reagent is coupled to the carrier.

15 Another aspect of the present invention is a pharmaceutical composition comprising the water-soluble carrier-linked prodrugs of formula (I) or a pharmaceutical salt thereof, and optionally one or more pharmaceutically acceptable excipients.

- 20 The pharmaceutical composition is further described in the following paragraphs.

The pharmaceutical composition comprising the water-soluble carrier-linked prodrug of formula (I) may be provided as a liquid composition or as a dry composition. Suitable methods of drying are, for example, spray-drying and lyophilization (freeze-drying). A preferred method of drying is lyophilization.

25

Preferably, the water-soluble carrier-linked prodrug of formula (I) is sufficiently dosed in the composition to provide a therapeutically and/or diagnostically effective amount of the biologically active moiety, in particular for at least one day in one application. More preferably, one application of the pharmaceutical composition comprising the water-soluble carrier-linked prodrug is sufficient for at least two days, such as three days, four days, five days, six days, or is sufficiently dosed for at least one week, such as for one week, two weeks,

30

three weeks, four weeks, five weeks, six weeks, seven weeks, eight weeks, three months, four months, five months or six months.

5 A pharmaceutical composition comprising a water-soluble carrier-linked prodrug or a pharmaceutically acceptable salt thereof of formula (I) preferably comprises one or more excipients.

10 Excipients may be categorized as buffering agents, isotonicity modifiers, preservatives, stabilizers, anti-adsorption agents, oxidation protection agents, viscosifiers/viscosity enhancing agents, or other auxiliary agents. In some cases, these ingredients may have dual or triple functions. The pharmaceutical compositions of water-soluble carrier-linked prodrugs according to the present invention preferably comprise one or more excipients, selected from the groups consisting of:

- 15 (i) Buffering agents: physiologically tolerated buffers to maintain pH in a desired range, such as sodium phosphate, bicarbonate, succinate, histidine, citrate and acetate, sulphate, nitrate, chloride, pyruvate. Antacids such as $\text{Mg}(\text{OH})_2$ or ZnCO_3 may be also used. Buffering capacity may be adjusted to match the conditions most sensitive to pH stability
- 20 (ii) Isotonicity modifiers: to minimize pain that can result from cell damage due to osmotic pressure differences at the injection depot. Glycerin and sodium chloride are examples. Effective concentrations can be determined by osmometry using an assumed osmolality of 285-315 mOsmol/kg for serum
- 25 (iii) Preservatives and/or antimicrobials: multidose parenteral preparations require the addition of preservatives at a sufficient concentration to minimize risk of patients becoming infected upon injection and corresponding regulatory requirements have been established. Typical preservatives include m-cresol, phenol, methylparaben, ethylparaben, propylparaben, butylparaben, chlorobutanol, benzyl alcohol,
- 30 phenylmercuric nitrate, thimerosal, sorbic acid, potassium sorbate, benzoic acid, chlorocresol, and benzalkonium chloride

(iv) Stabilizers: Stabilization is achieved by strengthening of the protein-stabilizing forces, by destabilization of the denatured state, or by direct binding of excipients to the protein. Stabilizers may be amino acids such as alanine, arginine, aspartic acid, glycine, histidine, lysine, proline, sugars such as glucose, sucrose, trehalose, polyols
5 such as glycerol, mannitol, sorbitol, salts such as potassium phosphate, sodium sulphate, chelating agents such as EDTA, hexaphosphate, ligands such as divalent metal ions (zinc, calcium, etc.), other salts or organic molecules such as phenolic derivatives. In addition, oligomers or polymers such as cyclodextrins, dextran, dendrimers, PEG or PVP or protamine or HSA may be used

10

(v) Anti-adsorption agents: Mainly ionic or non-ionic surfactants or other proteins or soluble polymers are used to coat or adsorb competitively to the inner surface of the composition's or composition's container. Suitable surfactants are e.g., alkyl sulfates, such as ammonium lauryl sulfate and sodium lauryl sulfate, alkyl ether sulfates, such
15 as sodium laureth sulfate and sodium myreth sulfate, sulfonates such as dioctyl sodium sulfosuccinates, perfluorooctanesulfonates, perfluorobutanesulfonates, alkyl benzene sulfonates, phosphates, such as alkyl aryl ether phosphates and alkyl ether phosphates, carboxylates, such as fatty acid salts (soaps) or sodium stearate, sodium lauroyl sarcosinate, perfluorononanoate, perfluorooctanoate, octenidine dihydrochloride,
20 quaternary ammonium cations such as cetyl trimethylammonium bromide, cetyl trimethylammonium chloride, cetylpyridinium chloride, polyethoxylated tallow amine, benzalkonium chloride, benzethonium chloride, 5-bromo-5-nitor-1,3-dioxane, dimethyldioctadecylammonium chloride, dioctadecyldimethylammonium bromide, zwitterionics, such as 3-[(3-cholamidopropyl)dimethylammonio]-1-propanesulfonate,
25 cocamidopropyl hydroxysultaine, amino acids, imino acids, cocamidopropyl betaine, lecithin, fatty alcohols, such as cetyl alcohol, stearyl alcohol, cetostearyl alcohol, oleyl alcohol, polyoxyethylene glycol alkyl ethers, such as octaethylene glycol monododecyl ether, pentaethylene glycol monododecyl ether, polyoxypropylene glycol alkyl ethers, glucoside alkyl ethers, such as decyl glucoside, lauryl glucoside,
30 octyl glucoside, polyoxyethylene glycol octylphenol ethers such as Triton X-100, polyoxyethylene glycol alkylphenol ethers such as nonoxynol-9, glycerol alkyl esters such as glyceryl laurate, polyoxyethylene glycol sorbitan alkyl esters such as polysorbates, sorbitan alkyl esters, cocamide MEA and cocamide DEA, dodecyl

dimethylamine oxide, block copolymers of polyethylene glycol and polypropylene glycol, such as poloxamers (Pluronic F-68), PEG dodecyl ether (Brij 35), polysorbate 20 and 80, other anti-absorption agents are dextran, polyethylene glycol, PEG-polyhistidine, BSA and HSA and gelatines. Chosen concentration and type of excipient depends on the effect to be avoided but typically a monolayer of surfactant is formed at the interface just above the CMC value

(vi) Lyo- and/or cryoprotectants: During freeze- or spray drying, excipients may counteract the destabilizing effects caused by hydrogen bond breaking and water removal. For this purpose sugars and polyols may be used but corresponding positive effects have also been observed for surfactants, amino acids, non-aqueous solvents, and other peptides. Trehalose is particularly efficient at reducing moisture-induced aggregation and also improves thermal stability potentially caused by exposure of protein hydrophobic groups to water. Mannitol and sucrose may also be used, either as sole lyo/cryoprotectant or in combination with each other where higher ratios of mannitol:sucrose are known to enhance physical stability of a lyophilized cake. Mannitol may also be combined with trehalose. Trehalose may also be combined with sorbitol or sorbitol used as the sole protectant. Starch or starch derivatives may also be used

(vii) Oxidation protection agents: antioxidants such as ascorbic acid, ectoine, methionine, glutathione, monothioglycerol, morin, polyethylenimine (PEI), propyl gallate, vitamin E, chelating agents such as citric acid, EDTA, hexaphosphate, thioglycolic acid

(viii) Spreading or diffusing agent: modifies the permeability of connective tissue through the hydrolysis of components of the extracellular matrix in the intrastitial space such as but not limited to hyaluronic acid, a polysaccharide found in the intercellular space of connective tissue. A spreading agent such as but not limited to hyaluronidase temporarily decreases the viscosity of the extracellular matrix and promotes diffusion of injected drugs.

(ix) Other auxiliary agents: such as wetting agents, viscosity modifiers, antibiotics, hyaluronidase. Acids and bases such as hydrochloric acid and sodium hydroxide are

auxiliary agents necessary for pH adjustment during manufacture.

In a general embodiment the pharmaceutical composition comprising the water-soluble carrier-linked prodrugs of formula (I) in either dry or liquid form may be provided as a single
5 or multiple dose composition.

In one embodiment of the present invention, the liquid or dry pharmaceutical composition comprising the water-soluble carrier-linked prodrug is provided as a single dose, meaning that the container in which it is supplied contains one pharmaceutical dose in case of
10 therapeutically active drugs.

Alternatively, in one embodiment, the liquid or dry pharmaceutical composition comprising the water-soluble carrier-linked prodrug is a multiple dose composition, meaning that the container in which it is supplied contains more than one therapeutic dose, i.e., a multiple dose
15 composition contains at least 2 doses in case of therapeutically active drugs. Such multiple dose composition of water-soluble carrier-linked prodrug can either be used for different patients in need thereof or can be used for one patient, wherein the remaining doses are stored after the application of the first dose until needed.

20 In another aspect of the present invention the pharmaceutical composition is in a container. Suitable containers for liquid or dry compositions are, for example, syringes, vials, vials with stopper and seal, ampouls, and cartridges. In particular, the liquid or dry composition comprising the water-soluble carrier-linked prodrug of formula (I) is provided in a syringe. If the pharmaceutical composition comprising the water-soluble carrier-linked prodrug is a dry
25 pharmaceutical composition the container preferably is a dual-chamber syringe. In such embodiment, said dry pharmaceutical composition is provided in a first chamber of the dual-chamber syringe and reconstitution solution is provided in the second chamber of the dual-chamber syringe.

30 Prior to applying the dry composition of water-soluble carrier-linked prodrug to a patient in need thereof, the dry composition is reconstituted. Reconstitution can take place in the container in which the dry composition of water-soluble carrier-linked prodrug is provided, such as in a vial, syringe, dual-chamber syringe, ampoule, and cartridge. Reconstitution is

done by adding a predefined amount of reconstitution solution to the dry composition. Reconstitution solutions are sterile liquids, such as water or buffer, which may contain further additives, such as preservatives and/or antimicrobials, such as, for example, benzylalcohol and cresol. Preferably, the reconstitution solution is sterile water. When a dry composition is
5 reconstituted, it is referred to as a “reconstituted pharmaceutical composition” or “reconstituted composition”.

An additional aspect of the present invention relates to the method of administration of a reconstituted or liquid pharmaceutical composition comprising the water-soluble carrier-
10 linked prodrug of formula (I). The pharmaceutical composition comprising water-soluble carrier-linked prodrug may be administered by methods of inhalation, injection or infusion, including intradermal, subcutaneous, intramuscular, intravenous, intraosseous, and intraperitoneal. Preferably, the pharmaceutical composition comprising water-soluble carrier-linked prodrug is administered subcutaneously.

15 The preferred method of administration for dry pharmaceutical compositions comprising the water-soluble carrier-linked prodrugs of the present invention is via inhalation.

Therefore, in a preferred embodiment, the present invention relates to a water-soluble carrier-
20 linked prodrug or a pharmaceutically acceptable salt thereof of formula (I) or a pharmaceutical composition of the present invention, for use as medicament for topical, enteral administration, parenteral administration, inhalation, injection, or infusion, intraarticular, intradermal, subcutaneous, intramuscular, intravenous, intraosseous, and intraperitoneal, intrathecal, intracapsular, intraorbital, intracardiac, transtracheal, subcuticular,
25 intraarticular, subcapsular, subarachnoid, intraspinal, intraventricular or intrasternal administration.

Therefore, in another preferred embodiment, the present invention relates to a water-soluble carrier-linked prodrug or a pharmaceutically acceptable salt thereof of formula (I) or a
30 pharmaceutical composition of the present invention, wherein such water-soluble carrier-linked prodrug or pharmaceutically acceptable salt thereof or pharmaceutical composition is suitable to be administered to a patient via topical, enteral or parenteral administration and by methods of external application, inhalation, injection or infusion, including intraarticular,

intradermal, subcutaneous, intramuscular, intravenous, intraosseous, and intraperitoneal, intrathecal, intracapsular, intraorbital, intracardiac, transtracheal, subcuticular, intraarticular, subcapsular, subarachnoid, intraspinal, intraventricular and intrasternal application.

5 A further aspect is a method of preparing a reconstituted composition comprising a diagnostically and/or therapeutically effective amount of water-soluble carrier-linked prodrug of formula (I), and optionally one or more pharmaceutically acceptable excipients, the method comprising the step of

- 10
- contacting the pharmaceutical composition comprising water-soluble carrier-linked prodrug of formula (I) with a reconstitution solution.

Another aspect is a reconstituted pharmaceutical composition comprising a diagnostically and/or therapeutically effective amount of the water-soluble carrier-linked prodrug of formula
15 (I), and optionally one or more pharmaceutically acceptable excipients.

Another aspect of the present invention is the method of manufacturing a dry composition of water-soluble carrier-linked prodrug. In one embodiment, such dry composition is obtainable by

- 20
- (i) admixing the water-soluble carrier-linked prodrug with one or more excipients,
 - (ii) transferring amounts equivalent to single or multiple doses into a suitable container,
 - (iii) drying the composition in said container, and
 - 25 (iv) sealing the container.

Suitable containers are vials, syringes, dual-chamber syringes, ampoules, and cartridges.

Another aspect of the present invention is a kit of parts.

30 If the administration device is simply a hypodermic syringe then the kit may comprise the syringe, a needle and a container comprising the dry pharmaceutical composition of water-

soluble carrier-linked prodrug suitable for use with the syringe and a second container comprising the reconstitution solution.

5 If the pharmaceutical composition is a liquid composition then the kit may comprise the syringe, a needle and a container comprising the liquid composition of water-soluble carrier-linked prodrug suitable for use with the syringe.

10 In more preferred embodiments, the injection device is other than a simple hypodermic syringe and so the separate container with reconstituted or liquid water-soluble carrier-linked prodrug is adapted to engage with the injection device such that in use the liquid composition in the container is in fluid connection with the outlet of the injection device. Examples of administration devices include but are not limited to hypodermic syringes and pen injector devices. Particularly preferred injection devices are the pen injectors in which case the container is a cartridge, preferably a disposable cartridge. Optionally, the kit of parts
15 comprises a safety device for the needle which can be used to cap or cover the needle after use to prevent injury.

A preferred kit of parts comprises a needle and a container containing the composition according to the present invention and optionally further containing a reconstitution solution,
20 the container being adapted for use with the needle. Preferably, the container is a dual-chamber syringe.

In another aspect, the invention provides a cartridge comprising a pharmaceutical composition of water-soluble carrier-linked prodrug as hereinbefore described for use with a pen injector
25 device. The cartridge may contain a single dose or multiplicity of doses of the water-soluble carrier-linked prodrug.

Yet another aspect of the present invention is a water-soluble carrier-linked prodrug or a pharmaceutically acceptable salt thereof of formula (I) or a pharmaceutical composition of the
30 present invention, for use as a medicament and/or diagnostic.

In another embodiment, the present invention relates to the use of a water-soluble carrier-linked prodrug of formula (I) or a pharmaceutically acceptable salt thereof, or a

pharmaceutical composition of the present invention for the preparation of a medicament and/or diagnostic, in particular for the treatment and/or diagnosis of diseases.

It is understood, that the disease that can be treated and/or diagnosed a water-soluble carrier-linked prodrug of the present invention or a pharmaceutically acceptable salt thereof, or a pharmaceutical composition of the present invention depends on the active agent. A water-soluble carrier-linked prodrug with an active agent moiety which has anti-cancer activity, like Doxorubicin, is typically administered to a cancer patient. Analogously, a water-soluble carrier-linked prodrug with an active agent moiety which has anti-inflammatory activity, like aminosalicic acid, is typically administered to a patient who suffers from an inflammatory disease, like rheumatoid arthritis, IBD or Morbus Crohn. Analogously, a water-soluble carrier-linked prodrug with an active agent moiety which has neurological activity is typically administered to a patient suffering from a neurological disease like Alzheimer's disease or Parkinson's disease. Analogously, a water-soluble carrier-linked prodrug with an active agent moiety which has anti-infective activity, like Gancyclovir, is typically administered to a patient suffering from a infectious disease like bacterial, viral, protozoal or fungal infection.

In case the water-soluble carrier-linked prodrugs according to the invention contain one or more acidic or basic groups, the invention also comprises their corresponding pharmaceutically or toxicologically acceptable salts, in particular their pharmaceutically utilizable salts. Thus, the water-soluble carrier-linked prodrugs according to the invention which contain acidic groups can be used according to the invention, for example, as alkali metal salts, alkaline earth metal salts or as ammonium salts. More precise examples of such salts include sodium salts, potassium salts, calcium salts, magnesium salts or salts with ammonia or organic amines such as, for example, ethylamine, ethanolamine, triethanolamine or amino acids. Water-soluble carrier-linked prodrugs according to the invention which contain one or more basic groups, i.e. groups which can be protonated, can be present and can be used according to the invention in the form of their addition salts with inorganic or organic acids. Examples for suitable acids include hydrogen chloride, hydrogen bromide, phosphoric acid, sulfuric acid, nitric acid, methanesulfonic acid, p-toluenesulfonic acid, naphthalenedisulfonic acids, oxalic acid, acetic acid, tartaric acid, lactic acid, salicylic acid, benzoic acid, formic acid, propionic acid, pivalic acid, diethylacetic acid, malonic acid, succinic acid, pimelic acid, fumaric acid, maleic acid, malic acid, sulfaminic acid,

phenylpropionic acid, gluconic acid, ascorbic acid, isonicotinic acid, citric acid, adipic acid, and other acids known to the person skilled in the art. If the water-soluble carrier-linked prodrugs according to the invention simultaneously contain acidic and basic groups in the molecule, the invention also includes, in addition to the salt forms mentioned, inner salts or
5 betaines (zwitterions). The respective salts can be obtained by customary methods which are known to the person skilled in the art like, for example by contacting these with an organic or inorganic acid or base in a solvent or dispersant, or by anion exchange or cation exchange with other salts. The present invention also includes all salts of the prodrugs which, owing to low physiological compatibility, are not directly suitable for use in pharmaceuticals but which
10 can be used, for example, as intermediates for chemical reactions or for the preparation of pharmaceutically acceptable salts.

Yet another aspect of the present invention is a method of treating, controlling, delaying or preventing in a mammalian patient, preferably in a human, in need of the treatment of one or
15 more conditions comprising administering to said patient a diagnostically and/or therapeutically effective amount of a water-soluble carrier-linked prodrug of the present invention or a pharmaceutical composition comprising the water-soluble carrier-linked prodrug of the present invention or a pharmaceutically acceptable salt thereof.
