FIG. 1
METHOD AND REAGENT FOR INHIBITING P-GLYCOPROTEIN (MDR-1 GENE)

BACKGROUND OF THE INVENTION

[0001] This invention relates to methods for treating cancer.

[0002] Transformation is a cumulative process whereby normal control of cell growth and differentiation is interrupted, usually through the accumulation of mutations affecting the expression of genes that regulate cell growth and differentiation.

SUMMARY OF THE INVENTION

[0004] This invention concerns use of a ribozyme targeted to the P-glycoprotein (mdr-1 gene) prior to and/or during administration of anticancer chemotherapeutic agents. Inclusion of such a ribozyme increases the susceptibility of the transformed cells to such agents.

[0005] Applicant notes that relapse of disease caused by cancerous cells after administration of chemotherapeutic agents is a major problem in obtaining lasting remissions in a clinic. In some neoplasias, relapse is caused by the expansion of a population of transformed cells resistant to the initial and subsequent forms of chemotherapy due to inappropriate expression of the mdr-1 gene, also called P-glycoprotein. Such expression is usually caused by selection of transformed cells that have amplified the mdr-1 gene and thus produce increased amounts of the mdr-1 gene product. Applicant describes treatment of and prevention of this condition by use of ribozymes targeted to the mRNA encoded by this gene.

[0006] The MDR1 gene encodes a 170 kDa integral membrane transport protein that confers resistance to certain chemotherapeutic agents such as colchicine, doxorubicin, actinomycin D and vinblastine (reviewed in Gottesman and Pastan 263 J. Biol. Chem. 12163, 1988). The gene has been isolated from both human and rodent cells selected in vitro for resistance to such agents (Rinsonon et al 309 Nature 626, 1984; and Roninson et al. 83 Proc. Natl. Acad. Sci USA, 4538, 1986), and the entire 4.5-kb MDR1 transcript encoding the human MDR1 has been sequenced (Chen et al., 47 Cell 381, 1986, EMBL accession # M14758). The gene is normally expressed in the cells of the colon, small intestine, kidney, liver and adrenal gland. High levels of MDR1 transcript have been found in adenocarcinomas that are intrinsically resistant to a broad range of chemotherapeutic agents, such as those derived from adrenal, kidney, liver and bowel.

[0007] Ribozymes are RNA molecules having an enzymatic activity which is able to repeatedly cleave other separate RNA molecules in a nucleotide base sequence specific manner. Such enzymatic RNA molecules can be targeted to virtually any RNA transcript and efficient cleavage has been achieved in vitro. Kim et al., 84 Proc. Natl. Acad. of Sci. USA 8788, 1987, Hazellof et al., 234 Nature 585, 1988, Cecch, 260 JAMA 3030, 1988, and Jefferies et al., 17 Nucleic Acid Research 1371, 1989.

[0008] Ribozymes act by first binding to a target RNA. Such binding occurs through the target RNA binding portion of a ribozyme which is held in close proximity to an enzymatic portion of the RNA which acts to cleave the target RNA. Thus, the ribozyme first recognizes and then binds a target RNA through complementary base-pairing, and once bound to the correct site, acts enzymatically to cut the target RNA. Strategic cleavage of such a target RNA will destroy its ability to direct synthesis of an encoded protein. After a ribozyme has bound and cleaved its RNA target it is released from that RNA to search for another target and can repeatedly bind and cleave new targets.

[0009] The enzymatic nature of a ribozyme is advantageous over other technologies, such as antisense technology (where a nucleic acid molecule simply binds to a nucleic acid target to block its translation) since the effective concentration of ribozyme necessary to effect a therapeutic treatment is lower than that of an antisense oligonucleotide. This advantage reflects the ability of the ribozyme to act enzymatically. Thus, a single ribozyme molecule is able to cleave many molecules of target RNA. In addition, the ribozyme is a highly specific inhibitor, with the specificity of inhibition depending not only on the base pairing mechanism of binding, but also on the mechanism by which the molecule inhibits the expression of the RNA to which it binds. That is, the inhibition is caused by cleavage of the RNA target and so specificity is defined as the ratio of the rate of cleavage of the targeted RNA over the rate of cleavage of non-targeted RNA. This cleavage mechanism is dependent upon factors additional to those involved in base pairing. Thus, it is thought that the specificity of action of a ribozyme is greater than that of antisense oligonucleotide binding the same RNA site.

[0010] Thus, the invention features novel enzymatic RNA molecules, or ribozymes, and methods for their use for inhibiting mdr-1 mRNA expression. Such ribozymes can be used in a method for treatment of disease caused by expression of the mdr-1 gene in man and other animals, including other primates. This conclusion, as noted above, is based upon the finding that many forms of cancer become unresponsive to certain chemotherapeutic agents as a result of overexpression of the mdr-1 gene. The advantage of using ribozymes of the present invention is their ability to specifically cleave the targeted mRNA, ultimately leading to a reduction in target gene activity through a decrease in level of the gene product. Use of mdr-1 specific ribozymes removes the mechanism of drug resistance used by transformed cells, and thus enhances drug therapies for tumor cell growth. These agents can be administered prior to and during chemotherapeutic treatment of those neoplasias known to have a high incidence of drug resistance, or can be used prophylactically for all neoplasias.

[0011] Thus, in the first aspect the invention features an enzymatic RNA molecule (or ribozyme) which cleaves mdr-1 mRNA (i.e., mRNA expressed from the mdr-1 gene), or its equivalent. In particular, the invention features hammerhead ribozymes designed to cleave accessible areas of the mdr-1 mRNA. Such areas include those listed below:
In a fourth related aspect, the invention features a method for treatment of an mdr-1 gene-related disease by administering to a patient an enzymatic RNA molecule which cleaves mdr-1 mRNA.

The invention provides a class of chemical cleaving agents which exhibit a high degree of specificity for the mRNA encoded by an mdr-1 gene. If desired, such ribozymes can be designed to target equivalent single-stranded RNAs by methods known in the art. The ribozyme molecule is preferably targeted to a highly conserved sequence region of the mdr-1 mRNA. Such enzymatic RNA molecules can be delivered exogenously to affected cells. In the preferred hammerhead motif the small size (less than 40 nucleotides, preferably between 32 and 36 nucleotides in length) of the molecule allows the cost of treatment to be reduced compared to other ribozyme motifs.

Synthesis of ribozymes greater than 100 nucleotides in length is very difficult using automated methods, and the therapeutic cost of such molecules is prohibitive. Delivery of ribozymes by expression vectors is primarily feasible using only ex vivo treatments. This limits the utility of this approach. In this invention, small ribozyme motifs (e.g., of the hammerhead structure, shown generally in FIG. 1) are used for exogenous delivery. The simple structure of these molecules also increases the ability of the ribozyme to invade targeted regions of the mRNA structure. Thus, unlike the situation when the hammerhead structure is included within longer transcripts, there are no non-ribozyme flanking sequences to interfere with correct folding of the ribozyme structure or with complementary binding of the ribozyme to the mRNA target region.

Other features and advantages of the invention will be apparent from the following description of the preferred embodiments thereof, and from the claims.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The drawing will first briefly be described.

DRAWING

FIG. 1 is a diagrammatic representation of a hammerhead motif ribozyme showing stems I, II and III (marked (I), (II) and (III) respectively) interacting with a target region. The 5' and 3' ends of both ribozyme and target are shown. Dashes indicate base-paired nucleotides.

TARGET SITES

Ribozymes targeting selected regions of the mdr-1 mRNA are preferably chosen to cleave the target RNA in a manner which inhibits translation of the mRNA. Selection of effective target sites within these critical regions of mRNA entails testing. The accessibility of the target mRNA to hybridization with various oligonucleotide probes. These studies can be performed using RNA probes and assaying accessibility by cleaving the hybrid molecule with RNaseH (see below). Alternatively, such a study can use ribozyme probes designed from secondary structure predictions of the RNAs, and assaying cleavage products by polyacrylamide gel electrophoresis (PAGE), to detect the presence of cleaved and uncleaved molecules.

The following is but one example of a method by which suitable target sites can be identified and is not
limiting in this invention. Generally, the method involves identifying potential cleavage sites for a hammerhead ribozyme, and then testing each of these sites to determine their suitability as targets by ensuring that secondary structure formation is minimal.

[0024] The sequence of the mRNA is studied to determine putative ribozyme cleavage sites. These sites represent the preferred sites for hammerhead or other ribozyme cleavage within these target RNAs.

[0025] Short RNA substrates corresponding to each of the gene sites are designed. Each substrate is composed of two to three nucleotides at the 5' and 3' ends that will not base pair with a corresponding ribozyme recognition region. The unpaired regions flank a central region of 12-14 nucleotides to which complementary arms in the ribozyme are designed.

[0026] The structure of each substrate sequence is predicted using a PC fold computer program. Sequences which give a positive free energy of binding are accepted. Sequences which give a negative free energy are modified by trimming one or two bases from each of the ends. If the modified sequences are still predicted to have a strong secondary structure, they are rejected.

[0027] After substrates are chosen, ribozymes are designed to each of the RNA substrates. Ribozyme folding is also analyzed using PC fold.

[0028] Ribozyme molecules are sought which form hammerhead motif stem II (see FIG. 1) regions and contain flanking arms which are devoid of intramolecular base pairing. Often the ribozymes are modified by trimming a base from the ends of the ribozyme, or by introducing additional base pairs in stem II to achieve the desired fold. Ribozymes with incorrect folding are rejected. After substrate/ribozyme pairs are found to contain correct intramolecular structures, the molecules are folded together to predict intermolecular interactions. A schematic representation of a ribozyme with its coordinate base pairing to its cognate target sequence is shown in FIG. 1.

[0029] Those targets thought to be useful as ribozyme targets can be tested to determine accessibility to nucleic acid probes in a ribonuclease H assay (see below). This assay provides a quick test of the use of the target site without requiring synthesis of a ribozyme. It can be used to screen for sites most suited for ribozyme attack.

[0030] Synthesis of Ribozymes

[0031] Ribozymes useful in this invention can be produced by gene transcription as described by Cech, supra, or by chemical synthesis. Chemical synthesis of RNA is similar to that for DNA synthesis. The additional 2'-OH group in RNA, however, requires a different protecting group strategy to deal with selective 3'-5' internucleotide bond formation, and with RNA susceptibility to degradation in the presence of bases. The recently developed method of RNA synthesis utilizing the t-butyldimethylsilyl group for the protection of the 2' hydroxyl is the most reliable method for synthesis of ribozymes. The method reproducibly yields RNA with the correct 3'-5' internucleotide linkages, with average coupling yields in excess of 99%, and requires only a two-step deprotection of the polymer.

[0032] A method, based upon H-phosphonate chemistry gives a relatively lower coupling efficiency than a method based upon phosphoroamidite chemistry. This is a problem for synthesis of DNA as well. A promising approach to scale-up of automatic oligonucleotide synthesis has been described recently for the H-phosphonates. A combination of a proper coupling time and additional capping of "failure" sequences gave high yields in the synthesis of oligodeoxyribonucleotides in scales in the range of 14 mmoles with as little as 2 equivalents of a monomer in the coupling step. Another alternative approach is to use soluble polymeric supports (e.g., polyethylene glycols), instead of the conventional solid supports. This method can yield short oligonucleotides in hundred milligram quantities per batch utilizing about 3 equivalents of a monomer in a coupling step.

[0033] Various modifications to ribozyme structure can be made to enhance the utility of ribozymes. Such modifications will enhance shelf-life, half-life in vitro, stability, and ease of introduction of such ribozymes to the target site, e.g., to enhance penetration of cellular membranes, and confer the ability to recognize and bind to targeted cells.

[0034] Exogenous delivery of ribozymes benefits from chemical modification of the backbone, e.g., by the overall negative charge of the ribozyme molecule being reduced to facilitate diffusion across the cell membrane. The present strategies for reducing the oligonucleotide charge include: modification of internucleotide linkages by methylphosphonates, use of phosphoramidites, linking oligonucleotides to positively charged molecules, and creating complex packages composed of oligonucleotides, lipids and specific receptors or effectors for targeted cells. Examples of such modifications include sulfur-containing ribozymes containing phosphorothioates and phosphorodithioates as internucleotide linkages in RNA. Synthesis of such sulfur-modified ribozymes is achieved by use of sulfur-transfer reagent, 3H-1,2-benzenedithiol-3-one 1,1-dioxide. Ribozymes may also contain ribose modified ribonucleotides. Pyrimidine analogues are prepared from uridine using a procedure employing dialkylamino sulphur trihalide (DAST) as a starting reagent. Ribozymes can also be either electrostatically or covalently attached to polymeric cations for the purpose of reducing charge. The polymer can be attached to the ribozyme by simply converting the 3'-end to a ribonucleoside dialdehyde which is obtained by a periodate cleavage of the terminal 2',3'-cis diol system. Depending on the specific requirements for delivery systems, other possible modifications may include different linker arms containing carboxyl, amino or thiol functionalities. Yet further examples include use of methylphosphonates and 2'-O-methylribose and 5' or 3' capping or blocking with m7GpppG or m3,5'GpppG.

[0035] For example, a kinase ribozyme is contacted with guanosine triphosphate and guanylytransferase to add a m7G cap to the ribozyme. After such synthesis, the ribozyme can be gel purified using standard procedure. To ensure that the ribozyme has the desired activity, it may be tested with and without the 5′ cap using standard procedures to assay both its enzymatic activity and its stability.

[0036] Synthetic ribozymes, including those containing various modifiers, can be purified by high pressure liquid chromatography (HPLC). Other liquid chromatography techniques, employing reverse phase columns and anion exchangers on silica and polymeric supports may also be used.
These follow an example of the synthesis of one ribozyme. A solid phase phosphoramidite chemistry was employed. Monomers used were 2‘-tert-butyl-dimethylsilyl cyanoethylphosphoramidites of uridine, N-benzyloxycarbonyl-cytosine, N-phenoxyacetyl adenine and guanine (Glen Research, Sterling, Va.). Solid phase synthesis was carried out on either an ABI 394 or 380B DNA/RNA synthesizer using the standard protocol provided with each machine. The only exception was that the coupling step was increased from 10 to 12 minutes. The phosphoramidite concentration was 0.1 M. Synthesis was done on a 1 μmole scale using a 1 μmole RNA reaction column (Glen Research). The average coupling efficiencies were between 97% and 98% for the 394 model, and between 97% and 99% for the 380B model, as determined by a calorimetric measurement of the released trityl cation.

Blocked ribozymes were cleaved from the solid support (e.g., CGG), and the bases and diphasoester moiety deprotected in a sterile vial by dry ethanolic ammonia (2 ml) at 55°C. For 16 hours. The reaction mixture was cooled on dry ice. Later, the cold liquid was transferred into a sterile screw cap vial and lyophilized.

To remove the 2‘-tert-butyl-dimethylsilyl groups from the ribozyme, the residue was suspended in 1 M tetra-n-butylammonium fluoride in dry THF (TBAF), using a 20 fold excess of the reagent for every silyl group, for 16 hours at ambient temperature (about 15-25°C). The reaction was quenched by adding an equal volume of sterile 1 M triethylamine acetate, pH 6.5. The sample was cooled and concentrated on a SpeedVac to the half of the initial volume.

The ribozymes were purified in two steps by HPLC on a C4 300 Å 5 mm DeltaPak column in an acetonitrile gradient.

The first step, or “trityl on” step, was a separation of 5′-DMT-protected ribozyme(s) from failure sequences lacking a 5′-DMT group. Solvents used for this step were: A (0.1 M triethylammonium acetate, pH 6.8) and B (acetonitrile). The elution profile was: 20% B for 10 minutes, followed by a linear gradient of 20% B to 50% B over 50 minutes, 50% B for 10 minutes, a linear gradient of 50% B to 100% B over 10 minutes, and a linear gradient of 100% B to 0% B over 10 minutes.

The second step was a purification of a completely deblocked ribozyme by a treatment of 2% trifluoroacetic acid on a C4 300 Å 5 mm DeltaPak column in an acetonitrile gradient. Solvents used for this second step were: A (0.1 M Triethylammonium acetate, pH 6.8) and B (80% acetonitrile, 0.1 M triethylammonium acetate, pH 6.8). The elution profile was: 5% B for 5 minutes, a linear gradient of 5% B to 15% B over 60 minutes, 15% B for 10 minutes, and a linear gradient of 15% B to 60% B over 10 minutes.

The fraction containing ribozyme was cooled and lyophilized on a SpeedVac. Solid residue was dissolved in a minimum amount of ethanol and sodium perchlorate in acetone. The ribozyme was collected by centrifugation, washed three times with acetone, and lyophilized.

Expression Vector

While synthetic ribozymes are preferred in this invention, those produced by expression vectors can also be used. In designing a suitable ribozyme expression vector the following factors are important to consider. The final ribozyme must be kept as small as possible to minimize unwanted secondary structure within the ribozyme. A promoter (e.g., a T7 promoter) should be chosen to be a relatively strong promoter, and expressible both in vitro and in vivo (e.g., by co-infection with the T7 RNA polymerase gene). Such a promoter should express the ribozyme at a level suitable to effect production of enough ribozyme to destroy a target RNA, but not at too high a level to prevent other cellular activities from occurring (unless cell death itself is desired).

A hairpin at the 5′ end of the ribozyme is useful to ensure that the required transcription initiation sequence (GG or GGG or GGGAG) does not bind to some other part of the ribozyme and thus affect regulation of the transcription process. The 5′ hairpin is also useful to protect the ribozyme from 3′-5′ exonucleases. A selected hairpin at the 3′ end of the ribozyme gene is useful since it acts as a transcription termination signal, and protects the ribozyme from 3′-5′ exonuclease activity. One example of a known termination signal is that present on the T7 RNA polymerase system. This signal is about 30 nucleotides in length. Other 3′ hairpins of shorter length can be used to provide good termination and RNA stability. Such hairpins can be inserted within the vector sequences to allow standard ribozymes to be placed in an appropriate orientation and expressed with such sequences attached.

Poly(A) tails are also useful to protect the 3′ end of the ribozyme. These can be provided by either including a poly(A) signal site in the expression vector (to signal a cell to add the poly(A) tail in vivo), or by introducing a poly(A) sequence directly into the expression vector. In the first approach the signal must be located to prevent unwanted secondary structure formation with other parts of the ribozyme. In the second approach, the poly(A) stretch may reduce in size over time when expressed in vivo, and thus the vector may need to be checked over time. Care must be taken in addition of a poly(A) tail which binds poly(A) binding proteins which prevent the ribozyme from acting.

Ribozyme Testing

Once the desired ribozymes are selected, synthesized and purified, they are tested in kinetic and other experiments to determine their utility. An example of such a procedure is provided below.

Preparation of Ribozyme

A crude synthetic ribozyme (typically 350 μg at a time) was purified by separation on a 15% denaturing polyacrylamide gel (0.75 mm thick, 40 cm long) and visualized by UV shadowing. Once excised, gel slices containing full length ribozyme were soaked in 5 ml gel elution buffer (0.5 M NH₄OAc, 1 mM EDTA) overnight with shaking at 4°C. The eluent was desalted over a C-18 matrix (Sep-Pak cartridges, Millipore, Milford, Mass.) and vacuum dried. The dried RNA was resuspended in 50-100 μl TE (TRIS 10 mM, EDTA 1 mM, pH 7.2). An aliquot of this solution was diluted 100 fold into 1 ml TE, half of which was used to spectrophotometrically quantitate the ribozyme solution. The concentration of this dilute stock was typically 150-800 nM. Purity of the ribozyme was confirmed by the presence of a single band on a denaturing polyacrylamide gel.
[0052] A ribozyme may advantageously be synthesized in two or more portions. Each portion of a ribozyme will generically have only limited or no enzymatic activity, and the activity will increase substantially (by at least 5-10 fold) when all portions are ligated (or otherwise juxtaposed) together. A specific example of hammerhead ribozyme synthesis is provided below.

[0053] The method involves synthesis of two (or more) shorter "half" ribozymes and ligation of them together using T4 RNA ligase. For example, to make a 34 mer ribozyme, two 17 mers are synthesized, one is phosphorylated, and both are gel purified. These purified 17 mers are then annealed to a DNA splint strand complementary to the two 17 mers. (Such a DNA splint is not always necessary.) This DNA splint has a sequence designed to locate the two 17 mer portions with one end of each adjacent each other. The juxtaposed RNA molecules are then treated with T4 DNA ligase in the presence of ATP. The 34 mer RNA so formed is then HPLC purified.

[0054] Preparation of Substrates

[0055] Approximately 10-30 pmole of unpurified sub- strate was radioactively 5' end-labelled with T4 polynucle-otide kinase using 25 pmole of [γ-32P]ATP. The entire labelling mix was separated on a 20% denaturing polyacrylamide gel and visualized by autoradiography. The full length band was excised and soaked overnight at 4°C in 100 µl of TE (10 mM Tris-HCl pH 7.6, 0.1 mM EDTA).

[0056] Kinetics Reactions

[0057] For reactions using short substrates (between 8 and 16 bases) a substrate solution was made 1× in assay buffer (75 mM Tris-HCl, pH 7.6, 0.1 mM EDTA, 10 mM MgCl2) such that the concentration of substrate was less than 1 nM. A ribozyme solution (typically 20 nM) was made 1× in assay buffer and four dilutions were made using 1×assay buffer. Fifteen µl of each ribozyme dilution (i.e., 20, 16, 12, 8 and 4 nM) was placed in a separate tube. These tubes and the substrate tube were pre-incubated at 37°C for at least five minutes.

[0058] The reaction was started by mixing 15 µl of sub- strate into each ribozyme tube by rapid pipetting (note that final ribozyme concentrations were 10, 8, 6, 4, 2 nM) 5 µl aliquots were removed at 15 or 30 second intervals and quenched with 5 µl stop solution (95% formamide, 20 mM EDTA xylene cyanol, and bromphenol blue dyes). Following the final ribozyme time point, an aliquot of the remaining substrate was removed as a zero ribozyme control.

[0059] The samples were separated on either 15% or 20% polyacrylamide gels. Each gel was visualized and quanti- tated with an Ambis beta scanner (Ambis Systems, San Diego, Calif.).

[0060] For the most active ribozymes, kinetic analyses were performed in substrate excess to determine Km and Kcat values.

[0061] For kinetic reactions with long RNA substrates (greater than 15 bases in length) the substrates were prepared by transcription using T7 RNA polymerase and defined templates containing a T7 promoter, and DNA encoding appropriate nucleotides of the mdr-1 gene RNA. The substrate solution is made 1× in assay buffer (75 mM Tris-HCl, pH 7.6; 0.1 mM EDTA; 10 µM MgCl2) and contains 58 nanomolar concentration of the long RNA molecules. The reaction is started by addition of gel purified ribozymes to 1 µM concentration. Aliquots are removed at 20, 40, 60, 80 and 100 minutes, then quenched by the addition of 5 µl stop solution. Cleavage products are sepa- rated using denaturing PAGE. The bands are visualized and quantitated with an Ambis beta scanner.

[0062] Kinetic Analysis

[0063] A simple reaction mechanism for ribozyme-mediated cleavage is:

\[ R + S \xrightarrow{k_1} [R:S] \xrightarrow{k_2} [R:P] \rightarrow R + P \]

where R=ribozyme, S=substrate, and P=products. The boxed step is important only in substrate excess. Because ribozyme concentration is in excess over substrate concentration, the concentration of the ribozyme-substrate complex ([R:S]) is constant over time except during the very brief time when the complex is being initially formed, i.e.:

\[ \frac{d[R:S]}{dt} = 0 \]

[0064] where t=time, and thus:

\[ (R)(S)k_2 = (R)(S)(k_2+k_1) \]

[0065] The rate of the reaction is the rate of disappearance of substrate with time:

\[ \text{Rate} = -\frac{d(S)}{dt} = k_2(RS) \]

[0066] Substituting these expressions:

\[ \frac{(R)(S)k_2}{k_2+k_1} = \frac{d(S)}{dt} \]

[0067] or:

\[ \frac{d(S)}{dt} = \frac{k_2k_1}{k_2+k_1}(R)dS \]

[0068] Integrating this expression with respect to time yields:

\[ \int_0^S \frac{dS}{S} = k_2k_1 \frac{(R)}{k_2+k_1} \]

[0069] where S=initial substrate. Therefore, a plot of the negative log of fraction substrate uncut versus time (in minutes) yields a straight line with slope:

[0070]...
slope = \frac{k_{p3} + k_1}{k_{r2} + k_1} (R) = k_{obs}

[0071] where \( k_{obs} \) = observed rate constant. A plot of slope \( (k_{obs}) \) versus ribozyme concentration yields a straight line with a slope which is:

\[
slope = \frac{k_{p3} + k_1}{k_{r2} + k_1} \quad \text{which is} \quad \frac{k_{r1}}{k_{r2}}
\]

[0072] Using these equations the data obtained from the kinetic experiments provides the necessary information to determine which ribozyme tested is most useful, or active. Such ribozymes can be selected and tested in vivo or ex vivo systems.

[0073] Liposome Preparation

[0074] Lipid molecules are dissolved in a volatile organic solvent (CHCl₃, methanol, diethylether, ethanol, etc.). The organic solvent is removed by evaporation. The lipid is hydrated into suspension with 0.1xphosphate buffered saline (PBS), then freeze-thawed 3x using liquid nitrogen and incubation at room temperature. The suspension is extruded sequentially through a 0.4 µm, 0.2 µm and 0.1 µm polycarbonate filters at maximum pressure of 800 psi. The ribozyme is mixed with the extruded liposome suspension and lyophilized to dryness. The lipid/ribozyme powder is rehydrated with water to one-tenth the original volume. The suspension is diluted to the minimum volume required for extrusion (0.4 ml for 1.5 ml barrel and 1.5 ml for 10 ml barrel) with 1xPBS and re-extruded through 0.4 µm, 0.2 µm, 0.1 µm polycarbonate filters. The liposome entrapped ribozyme is separated from untrapped ribozyme by gel filtration chromatography (SEPHAROSE CL-4B, BIOGEL AS). The liposome extracts are pooled and sterilized by filtration through a 0.2 µm filter. The free ribozyme is pooled and recovered by ethanol precipitation. The liposome concentration is determined by incorporation of a radioactive lipid. The ribozyme concentration is determined by labeling with ³²P. Rossi et al., 1992 supra (and references cited therein) describe other methods suitable for preparation of liposomes.

[0075] In Vivo Assay

[0076] The efficacy of action of a chosen ribozyme may be tested in vivo by use of cell cultures sensitive to mr-1 gene expression, using standard procedures.

[0077] Ribonuclease Protection Assay

[0078] The accumulation of target mRNA in cells or the cleavage of the mRNA by ribozymes or RNaseH (in vitro or in vivo) can be quantitated using an RNase protection assay.

[0079] In this method, antisense riboprobes are transcribed from template DNA using T7 RNA polymerase (U.S. Biochemicals) in 20 µl reactions containing 1x transcription buffer (supplied by the manufacturer), 0.2 mm ATP, GTP and UTP, 1 U/µl pancreatic RNase inhibitor (Boehringer Mannheim Biochemicals) and 200 µCi ³²P-labeled CTP (800 Ci/mmol, New England Nuclear) for 1 h at 37°C. Template DNA is digested with 1 U RNase-free DNase I (U.S. Biochemicals, Cleveland, Ohio) at 37°C for 15 minutes and unincorporated nucleotides removed by G-50 SEPHADEX spin chromatography.

[0080] In a manner similar to the transcription of antisense probe, the target mRNA can be transcribed in vitro using a suitable DNA template. The transcript is purified by standard methods and digested with ribozyme at 37°C according to methods described later.

[0081] Alternatively, cells expressing the target mRNA are harvested into 1 ml of PBS, transferred to a 1.5 ml EPENNDORF tube, pelleted for 30 seconds at low speed in a microcentrifuge, and lysed in 70 µl of hybridization buffer (4 M guanidine isothiocyanate, 0.1% sarcosyl, 25 mM sodium citrate, pH 7.5). Cell lysate (45 µl) or defined amounts of in vitro transcript (also in hybridization buffer) is then combined with 5 µl of hybridization buffer containing 5x10⁷ cpm of each antisense riboprobe in 0.5 ml Eppendorf tubes, overlaid with 25 µl mineral oil, and hybridized accomplished by heating overnight at 55°C. The hybridization reactions are diluted into 0.5 ml RNase solution (20 U/ml RNase A, 2 U/ml RNase T1, 10 µl/ml RNase-free DNase I in 0.4 M NaCl), heated for 30 minutes at 37°C, and 10 µl of 20% SDS and 10 µl of Proteinase K (10 mg/ml) added, followed by an additional 30 minutes incubation at 37°C. The hybrids are partially purified by extraction with 0.5 ml of a 1:1 mixture of phenol/chloroform; aqueous phases are combined with 0.5 ml isopropanol, and RNase-resistant hybrids pelleted for 10 minutes at room temperature (about 20°C) in a microcentrifuge. Pellets are dissolved in 10 µl loading buffer (95% formamide, 1xTBE, 0.1% bromophenol blue, 0.1% xylene cyanole), heated to 95°C for five minutes, cooled on ice, and analyzed on 4% polyacrylamide/7 M urea gels under denaturing conditions.

[0082] Ribozyme Stability

[0083] The chosen ribozyme can be tested to determine its stability, and thus its potential utility. Such a test can also be used to determine the effect of various chemical modifications (e.g., addition of a poly(A) tail) on the ribozyme stability and thus aid selection of a more stable ribozyme. For example, a reaction mixture contains 1 to 5 pmoles of 5’ (kinased) and/or 3’ labeled ribozyme, 15 µg of cytosolic extract and 2.5 mM MgCl₂, in a total volume of 100 µl. The reaction is incubated at 37°C. Eight µl aliquots are taken at timed intervals and mixed with 8 µl of a stop mix (20 mM EDTA, 95% formamide). Samples are separated on a 15% acrylamide sequencing gel, exposed to film, and scanned with an Ambis.

[0084] A 3’-labelled ribozyme can be formed by incorporation of the ³²P-labeled cytidylyl at the 3’ OH using poly(A) polymerase. For example, the poly(A) polymerase reaction contains 40 mM Tris, pH 8.0, 10 mM MgCl₂, 250 mM NaCl, 2.5 mM MnCl₂; 3 µl ³²P-cytidylyl, 500 Ci/µM; and 6 units poly(A) polymerase in a total volume of 50 µl. The reaction mixture is incubated for 30 minutes at 37°C.

[0085] Effect of Base Substitution Upon Ribozyme Activity

[0086] To determine which primary structural characteristics could change ribozyme cleavage of substrate, minor base changes can be made in the substrate cleavage region recognized by a specific ribozyme. For example, the sub-
strate sequences can be changed at the central "C" nucleotide, changing the cleavage site from a GUC to a GUA motif. The \( K_{\text{m}}/K_{\text{cat}} \) values for cleavage using each substrate are then analyzed to determine if such a change increases ribozyme cleavage rates. Similar experiments can be performed to address the effects of changing bases complementary to the ribozyme binding arms. Changes predicted to maintain strong binding to the complementary substrate are preferred. Minor changes in nucleotide content can alter ribozyme/substrate interactions in ways which are unpredictable based upon binding strength alone. Structures in the catalytic core region of the ribozyme recognize trivial changes in either substrate structure or the three dimensional structure of the ribozyme/substrate complex.

[0087] To begin optimizing ribozyme design, the cleavage rates of ribozymes containing varied arm lengths, but targeted to the same length of short RNA substrate can be tested. Minimal arm lengths are required and effective cleavage varies with ribozyme/substrate combinations.

[0088] The cleavage activity of selected ribozymes can be assessed using mdr-1 mRNA-homologous substrates. The assays are performed in ribozyme excess and approximate \( K_{\text{m}}/K_{\text{cat}} \) values obtained. Comparison of values obtained with short and long substrates indicates utility in vivo of a ribozyme.

[0089] Intracellular Stability of Liposome-Delivered Ribozymes

[0090] Ribozymes

[0091] To test the stability of a chosen ribozyme in vivo the following test is useful. Ribozymes are \( ^{32} \text{P} \)-end labeled, entrapped in liposomes and delivered to mdr-1 mRNA containing cells for three hours. The cells are fractionated and ribozyme is purified by phenol/chloroform extraction. Alternatively, cells (1×10^7, T-175 flask) are scraped from the surface of the flask and washed twice with cold PBS. The cells are homogenized by douncing 35 times in 4 ml of TSE (10 mM Tris, pH 7.4, 0.25 M Sucrose, mM EDTA) Nuclei are pelleted at 1000xg for 10 minutes. Subcellular organelles (the membrane fraction) are pelleted at 200,000xg for two hours using an SW60 rotor. The pellet is resuspended in 1 ml of H buffer (0.25 M Sucrose, 50 mM HEPES, pH 7.4). The supernatant contains the cytoplasmic fraction (in approximately 3.7 ml). The nuclear pellet is resuspended in 1 ml of 65% sucrose in TM (50 mM Tris, pH 7.4, 2.5 mM MgCl₂) and banded on a sucrose step gradient (1 ml nuclei in 65% sucrose TM, 1 ml 60% sucrose TM, 1 ml 55% sucrose TM, 50% sucrose TM, 300 ul 25% sucrose TM) for one hour at 37,000xg with an SW60 rotor. The nuclear band is harvested and diluted to 10% sucrose with TM buffer. Nuclei are pelleted at 37,000xg using an SW60 rotor for 15 minutes and the pellet resuspended in 1 ml of TM buffer. Aliquots are size fractionated on denaturing polyacrylamide gels and the intracellular localization determined. By comparison to the migration rate of newly synthesized ribozyme, the various fraction containing intact ribozyme can be determined.

[0092] To investigate modifications which would lengthen the half-life of ribozyme molecules intracellularly, the cells may be fractioned as above and the purity of each fraction assessed by assaying enzyme activity known to exist in that fraction.

[0093] The various cell fractions are frozen at 70°C. and used to determine relative nuclease resistances of modified ribozyme molecules. Ribozyme molecules may be synthesized with 5 phosphorothioate (ps), or 2'-omethyl (2'-OMe) modifications at each end of the molecule. These molecules and a phosphodiester version of the ribozyme are end-labeled with \( ^{32} \text{P} \) and ATP using T4 polynucleotid kinase. Equal concentrations are added to the cell cytoplasmic extracts and aliquots of each taken at 10 min. intervals. The samples are size fractionated by denaturing PAGE and relative rates of nuclease resistance analyzed by scanning the gel with an Ambis \( \beta \)-scanner. The results show whether the ribozymes are digested by the cytoplasmic extract, and which versions are relatively more nuclease resistant. Modified ribozymes generally maintain 80-90% of the catalytic activity of the native ribozyme when short RNA substrates are employed.

[0094] Unlabeled, 5' end-labeled or 3' end-labeled ribozymes can be used in the assays. These experiments can also be performed with human cell extracts to verify the observations.

[0095] Administration of Ribozyme

[0096] Selected ribozymes can be administered prophylactically, or to patients expressing mdr-1 mRNA, e.g., by exogenous delivery of the ribozyme to an infected tissue by means of an appropriate delivery vehicle, e.g., a liposome, a controlled release vehicle, by use of iontophoresis, or ion paired molecules, or covalently attached adducts, and other pharmacologically approved methods of delivery. Routes of administration include intramuscular, aerosol, oral (tablet or pill form), topical, systemic, ocular, intraperitoneal and/or intrathecal. Expression vectors for immunization with ribozymes and/or delivery of ribozymes are also suitable.

[0097] The specific delivery route of any selected ribozyme will depend on the use of the ribozyme. Generally, a specific delivery program for each ribozyme will focus on unmodified ribozyme uptake with regard to intracellular localization, followed by demonstration of efficacy. Alternatively, delivery to these same cells in an organ or tissue of an animal can be pursued. Uptake studies will include uptake assays to evaluate cellular ribozyme uptake, regardless of the delivery vehicle or strategy. Such assays will also determine the intracellular localization of the ribozyme following uptake, ultimately establishing the requirements for maintenance of steady-state concentrations within the cellular compartment containing the target sequence (nucleus and/or cytoplasm). Efficacy and cytotoxicity can then be tested. Toxicity will not only include cell viability but also cell function.

[0098] Some methods of delivery that may be used include:

- a. encapsulation in liposomes,
- b. transduction by retroviral vectors,
- c. conjugation with cholesterol,
- d. localization to nuclear compartment utilizing nuclear targeting site found on most nuclear proteins,
- e. neutralization of charge of ribozyme by using nucleotide derivatives, and
- f. use of blood stem cells to distribute ribozymes throughout the body.
At least three types of delivery strategies are useful in the present invention, including: ribozyme modifications, particle carrier drug delivery vehicles, and retroviral expression vectors. Unmodified ribozymes, like most small molecules, are taken up by cells, albeit slowly. To enhance cellular uptake, the ribozyme may be modified essentially at random, in ways which reduce its charge but maintains specific functional groups. This results in a molecule which is able to diffuse across the cell membrane, thus removing the permeability barrier.

Modification of ribozymes to reduce charge is just one approach to enhance the cellular uptake of these larger molecules. The random approach, however, is not advisable since ribozymes are structurally and functionally more complex than small drug molecules. The structural requirements necessary to maintain ribozyme catalytic activity are well understood by those in the art. These requirements are taken into consideration when designing modifications to enhance cellular delivery. The modifications are also designed to reduce susceptibility to nuclease degradation. Both of these characteristics should greatly improve the efficacy of the ribozyme. Cellular uptake can be increased by several orders of magnitude without having to alter the phosphodiester linkages necessary for ribozyme cleavage activity.

Chemical modifications of the phosphate backbone will reduce the negative charge allowing free diffusion across the membrane. This principle has been successfully demonstrated for antisense DNA technology. The similarities in chemical composition between DNA and RNA make this a feasible approach. In the body, maintenance of an external concentration will be necessary to drive the diffusion of the modified ribozyme into the cells of the tissue. Administration routes which allow the desired tissue to be exposed to a transient high concentration of the drug, which is slowly dissipated by systemic adsorption are preferred. Intravenous administration with a drug carrier designed to increase the circulation half-life of the ribozyme can be used. The size and composition of the drug carrier restricts rapid clearance from the blood stream. The carrier, made to accumulate at the site of infection, can protect the ribozyme from degradative processes.

Drug delivery vehicles are effective for both systemic and topical administration. They can be designed to serve as a slow release reservoir, or to deliver their contents directly to the target cell. An advantage of using direct delivery drug vehicles is that multiple molecules are delivered per uptake. Such vehicles have been shown to increase the circulation half-life of drugs which would otherwise be rapidly cleared from the blood stream. Some examples of such specialized drug delivery vehicles which fall into this category are liposomes, hydrogels, cyclodextrins, biodegradable nanocapsules, and bioadhesive microspheres.

From this category of delivery systems, liposomes are preferred. Liposomes increase intracellular stability, increase uptake efficiency and improve biological activity.

Liposomes are hollow spherical vesicles composed of lipids arranged in a similar fashion as those lipids which make up the cell membrane. They have an internal aqueous space for entrapping water soluble compounds and range in size from 0.05 to several microns in diameter. Several studies have shown that liposomes can deliver RNA to cells and that the RNA remains biologically active.

For example, a liposome delivery vehicle originally designed as a research tool, Lipofectin, has been shown to deliver intact mRNA molecules to cells yielding production of the corresponding protein.

Liposomes offer several advantages: They are non-toxic and biodegradable in composition; they display long circulation half-lives; and recognition molecules can be readily attached to their surface for targeting to tissues. Finally, cost effective manufacture of liposome-based pharmaceuticals, either in a liquid suspension or lyophilized product, has demonstrated the viability of this technology as an acceptable drug delivery system.

Other controlled release drug delivery systems, such as nanoparticles and hydrogels may be potential delivery vehicles for a ribozyme. These carriers have been developed for chemotherapeutic agents and protein-based pharmaceuticals, and consequently, can be adapted for ribozyme delivery.

Topical administration of ribozymes is advantageous since it allows localized concentration at the site of administration with minimal systemic adsorption. This simplifies the delivery strategy of the ribozyme to the disease site and reduces the extent of toxicological characterization. Furthermore, the amount of material to be applied is far less than that required for other administration routes. Effective delivery requires the ribozyme to diffuse into the infected cells. Chemical modification of the ribozyme to neutralize negative charge may be all that is required for penetration. However, in the event that charge neutralization is insufficient, the modified ribozyme can be co-formulated with permeability enhancers, such as Azone or oleic acid, in a liposome. The liposomes can either represent a slow release presentation vehicle in which the modified ribozyme and permeability enhancer transfer from the liposome into the infected cell, or the liposome phospholipids can participate directly with the modified ribozyme and permeability enhancer in facilitating cellular delivery. In some cases, both the ribozyme and permeability enhancer can be formulated into a suppository formulation for slow release.

Ribozymes may also be systemically administered. Systemic absorption refers to the accumulation of drugs in the blood stream followed by distribution throughout the entire body. Administration routes which lead to systemic absorption include: intravenous, subcutaneous, intraperitoneal, intranasal, intracath and ophthalmic. Each of these administration routes expose the ribozyme to an accessible diseased tissue. Subcutaneous administration drains into a localized lymph node which proceeds through the lymphatic network into the circulation. The rate of entry into the circulation has been shown to be a function of molecular weight or size. The use of a liposome or other drug carrier localizes the ribozyme at the lymph node. The ribozyme can be modified to diffuse into the cell, or the lipidosome can directly participate in the delivery of either the unmodified or modified ribozyme to the cell.

A liposome formulation which can deliver oligonucleotides to lymphocytes and macrophages is also useful. This oligonucleotide delivery system inhibits viral proliferation in these viruses that infect primary immune cells. Whole blood studies show that the formulation is taken up by 90% of the lymphocytes after 8 hours at 37° C. Preliminary biodistribution and pharmacokinetic studies yielded
70% of the injected dose/gm of tissue in the spleen after one hour following intravenous administration.

[0117] Intraperitoneal administration also leads to entry into the circulation with the molecular weight or size controlling the rate of entry.

[0118] Liposomes injected intravenously show accumulation in the liver, lung and spleen. The composition and size can be adjusted so that this accumulation represents 30% to 40% of the injected dose. The remaining dose circulates in the blood stream for up to 24 hours.

[0119] The chosen method of delivery should result in cytoplasmic accumulation and molecules should have some nuclease-resistance for optimal dosing. Nuclear delivery may be used but is less preferable. Most preferred delivery methods include liposomes (10-400 nm), hydrogels, controlled-release polymers, microinjection or electroporation (for ex vivo treatments) and other pharmaceutically applicable vehicles. The dosage will depend upon the disease indication and the route of administration but should be between 100-200 mg/kg of body weight/day. The duration of treatment will extend through the course of the disease symptoms, possibly continuously. The number of doses will depend upon disease delivery vehicle and efficacy data from clinical trials.

[0120] Establishment of therapeutic levels of ribozyme within the cell is dependent upon the rate of uptake and degradation. Decreasing the degree of degradation will prolong the intracellular half-life of the ribozyme. Thus, chemically modified ribozymes, e.g., with modification of the phosphate backbone, or capping of the 5' and 3' ends of the ribozyme with nucleotide analogs may require different dosaging. Descriptions of useful systems are provided in the art cited above, all of which is hereby incorporated by reference herein.

[0121] The claimed ribozymes are also useful as diagnostic tools to specifically or non-specifically detect the presence of a target RNA in a sample. That is, the target RNA, if present in the sample, will be specifically cleaved by the ribozyme, and thus can be readily and specifically detected as smaller RNA species. The presence of such smaller RNA species is indicative of the presence of the target RNA in the sample.

[0122] Other embodiments are within the following claims.

(xi) SEQUENCE DESCRIPTION: SEQ ID NO: 8:
GGAGAAUGA C
1. An enzymatic RNA molecule which is active to specifically cleave mRNA expressed from an mdr 1 gene.

2. The enzymatic RNA molecule of claim 1 which cleaves the sequence shown as any of SEQ. ID. NOs. 1-9.

3. The enzymatic RNA molecule of claim 1 wherein said RNA molecule is in a hammerhead motif.

4. The enzymatic RNA molecule of claim 1 wherein said RNA molecule is in a hairpin, hepatitis Delta virus, group 1 intro, or RasP RNA motif.

5. A mammalian cell including an enzymatic RNA molecule of claim 1.

6. A mammalian cell including an enzymatic RNA molecule of claim 2.

7. A mammalian cell including an enzymatic RNA molecule of claim 3.

8. A mammalian cell including an enzymatic RNA molecule of claim 4.

9. The cell of claim 5, wherein said cell is a human cell.

10. The cell of claim 6, wherein said cell is a human cell.

11. The cell of claim 7, wherein said cell is a human cell.

12. The cell of claim 8, wherein said cell is a human cell.

13. An expression vector including nucleic acid encoding the catalytic RNA molecule of any of claim 1, in a manner which allows expression of that enzymatic RNA molecule within a mammalian cell.

14. An expression vector including nucleic acid encoding the catalytic RNA molecule of any of claim 2, in a manner which allows expression of that enzymatic RNA molecule within a mammalian cell.

15. An expression vector including nucleic acid encoding the catalytic RNA molecule of any of claim 3, in a manner which allows expression of that enzymatic RNA molecule within a mammalian cell.
