SYNTHESIS OF CARBAMOYL-PYRIDINE HIV INTEGRASE INHIBITORS AND INTERMEDIATES

Field of the Invention

The present invention comprises modifications of known processes for synthesizing compounds having HIV integrase inhibitory activity.

Background of the Invention

WO 2006/116764 published 2 November 2006, incorporated by reference in its entirety, describes various compounds and detailed synthetic schemes for their preparation. In particular, a reaction sequence is depicted at page 79 thereof wherein 3-benzyloxy-2-methyl-1H-pyridine-4-one of formula 3 is there brominated to the bromopyridine 4 there, which is then reacted with methanol and carbon monoxide to yield the nicotinic acid methyl ester 5 there which is after several steps reacted with a benzylamine to create the amide side chain-containing pyridine 10. Thus, the amide sidechain is in place before creation of the $Z^1Z^2$ ring of the final product formula (I) therein in the reaction depicted at page 80 from 16 to 17-1.

A second reaction sequence is depicted at page 113 of WO 2006/116764 wherein a pyrrolidine compound 102 is allowed to condense into a tricyclic compound 103 which is then brominated to yield the bromine compound 104 which is then reacted with a benzylamine to create the amide side chain-containing tricyclic compound 105 therein. Thus, the bromination takes place after creation of the $Z^1Z^2$ ring of the final product of formula (I) therein.

Summary of the Invention

Processes are provided which utilize an early bromination step in the construction of compounds useful as having HIV integrase inhibitory activity as set forth in WO 2006/116764. The bromination provides the leaving group for attachment of an amide side chain on a pyridone ring.

The product (Ia) of a synthetic sequence can be condensed with an amine, eg of the formula H₂NCH₂CH₂CH₂OH, brominated if R⁰ is H, carbonylated and amidated and finally, debenzylated to yield a compound of WO 2006/116764 designated (I-7) at page 240 wherein (R)₄ is 4-F and R⁰ is H. Alternatively, such a compound may be synthesized by starting with (I) where R⁰ is p-F-phenyl-CH₂-NH-C(O)-, R³ is H, P¹ is benzyl (Bn) and P³ is a carboxy protecting group.

In more detail, step i) can be carried out out in a protic or aprotic solvent such as EtOH, THF or DMF at a temperature of about 50-150°C for about 1-10 hours.

In more detail, step ii) can be carried out for the diol starting material (VI) with an oxidizing agent such as NaIO₄, RuO₄ or Pb(OAc)₄ in a solvent such as H₂O, MeOH or CH₂CN at ambient temperature for one or more hours. For the acetate type starting material such as (V), reaction may be in an acid such as HCl, CF₃COOH or HCOH optionally with heating.

Step ii) can also involve refuralenization at the R⁰ position, eg R⁰=H to R⁰=Br optionally with further refunctionalization to R⁰=R²-X-NR¹-C(O)-. Step ii) can also involve refunctionalization of P³, eg P³=H to P³=Me.

In more detail, step P-1) can be carried out by treating a compound of formula I-I with a bromine source including but not limited to N-bromosuccinimide or bromine in a solvent such as N,N-dimethyl formamide, THF or acetic acid and the like. This transformation can be run particularly at a temperature of -10°C to 50°C to produce a compound of formula II-II.

In more detail, step P-2) can be carried out by treating a compound of formula II-II with 2,4-difluorophenyl-CH₂-NH₂, carbon monoxide, a suitable base and palladium (0) source and optionally an appropriate ligand in an inert solvent optionally with heating. The carbon monoxide can be at atmospheric pressure (14.7 psi) or at elevated pressure particularly in the range of up to 60 psi but in some cases higher pressures may be required. Bases include but are not limited to tertiary amine bases such as diisopropylethylamine and triethylamine and the like. Inorganic bases such as potassium acetate and potassium phosphate are also bases of significance. Suitable sources of Pd (0) include but are not limited to tetrakis triphenylphosphine palladium (0). In some cases a Pd (II) precursor can be used to generate Pd (0) in situ. Suitable Pd (II) precursors include but are not limited to Pd(OAc)₂, Pd(OCOCF₃)₂ and ligands include Xantphos,
diphenylphosphinoferrocene (dpff), triphenylphosphine and the like. Solvents include 
N,N-dimethyl formamide, THF, toluene, DMSO and the like. Heating the mixture is 
optionally used in the range from ambient to 150 °C.
