ABSTRACT
There is herein described an improved adhesive sheeted roll. More particularly, there is described an improved adhesive sheeted roll and individual sheets making up the sheeted roll which contain no silicones.
ADHESIVE SHEETED ROLL
CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims benefit of priority from U.S. Provisional Application No. 61/223,793, filed Jul. 8, 2009 the contents of which are incorporated herein by reference.

FIELD OF THE INVENTION

[0002] The present invention relates to an improved adhesive sheeted roll. More particularly, the present invention relates to an improved adhesive sheeted roll and individual embossed sheets making up the sheeted roll which contain no silicones.

BACKGROUND OF THE INVENTION

[0003] In contact cleaning, adhesive rolls have a release coating on a non-adhesive side. This prevents the adhesive from permanently sticking to the non-adhesive side when wound up in a roll. The adhesive must however have some adhesion to the release coat to maintain the integrity of the roll.

[0004] Contact cleaning processes are known where a wound sheeted roll is used to remove impurities from a surface. In this regard we refer to WO 03/091138 which is incorporated herein by reference. Previous contact cleaning processes have used a thin coating of silicone to form a release coating. However, silicones have been found to present several disadvantages. For example, silicones are now known to be environmentally unfriendly and silicones from shampoos and conditioners have been found to form a sludge in the oceans which kills living organisms. Silicones are also chemically inert and are not easily broken down. More importantly, products containing silicones cannot be recycled and are not biodegradable.

[0005] The silicone coating during a contact cleaning process can also rub off if it is not properly cured and may therefore be deposited on the surface of parts being cleaned. This can also cause subsequent processing issues. Moreover, silicone on a surface will prevent inks or coatings sticking to the surface causing the product to be scrapped.

[0006] Many customers will also not allow any product containing silicone to be used in their plants.

[0007] One aspect of the present invention obviates or mitigates at least one or more of the aforementioned problems.

[0008] A further aspect of the present invention provides an improved adhesive sheeted roll.

[0009] Yet a further aspect of the present invention provides an improved adhesive sheeted roll containing no silicones suitable for use in contact cleaning.

SUMMARY OF THE INVENTION

[0010] According to a first aspect of the present invention there is provided a sheeted roll for use in contact cleaning comprising:

[0011] a roll core;

[0012] at least one sheet of adhesive material removably attached to the roll core;

[0013] wherein the adhesive sheet has two sides, a first side comprising adhesive and a second side comprising an embossed surface with the proviso that the adhesive sheet contains no silicones.

[0014] The present invention therefore resides in the provision of a sheeted roll suitable for use in contact cleaning which contains no silicones. The individual sheets and adhesive material are therefore free of silicones. The adhesive sheets may also comprise anti-static additives and/or bacteriocides.

[0015] The sheets of adhesive material may therefore comprise an embossed surface facing inwardly on the individual adhesive sheets that do not have any silicones which is a particular advantage over prior art adhesive sheets. The sheeted roll as a whole therefore has no silicones.

[0016] The at least one sheet of adhesive material may be wound around the circumference of the roll core. The sheets of adhesive material may be greater in length than the circumferential length of the roll core. Each end of the sheets of adhesive material may be abutted to an end of another sheet. The other end of each sheet may be abutted to another end of said sheet.

[0017] Typically, there may at least two or more or a plurality of sheets of adhesive material wound, for example, around each other. On top of a first sheet of adhesive material there may be subsequent sheets of adhesive material removable attached thereon. The subsequent sheets may therefore be wound onto and removably attached on previous sheets of material on, for example, the roll core. The said at least one sheet and subsequent sheets of adhesive material may therefore provide an adhesive surface holding the sheets to one another on the roll core.

[0018] In particular embodiments the sheet of adhesive material may be manufactured from a thermoplastic polymer in the form of a thin film such as a polypropylene film product which has no silicone release coating. Preferably, the polypropylene film may be made from polypropylene with a molecular weight of about 150-270 kg mol⁻¹.

[0019] The thermoplastic polymer film (e.g., polypropylene) may have a thickness of about 30-200 microns.

[0020] The thermoplastic polymer sheets may have a size of about 20 cm x 10 cm.

[0021] The sheet of adhesive material may also comprise an embossed surface to minimize the contact area of the adhesive on the film and so reduce the adhesion to another sheet to a level where the adhesive roll maintains its integrity but the adhesive sheets can be easily unwound and replaced/re-freshed when necessary. The embossed surface facilitates removal of each sheet.

[0022] The embossing may be in the form of a 3-dimensional regular or irregular pattern formed on one side of the adhesive sheets. The embossing may form an imprint with a depth of about 0.2-5 microns and preferably about 1-2 microns.

[0023] The embossing on the film may reduce the contact area of the adhesive on the film by about less than 50%, 60%, 70%, 80% or 90%.

[0024] The embossing may be defined as an "orange peel" emboss which provides a random surface. The embossing may be achieved using any typical process and may therefore be achieved using an embossing cylinder which has an embossing pattern (e.g., the "orange peel" pattern) etched on the outer surface of the cylinder. The embossing cylinder may be rolled over the film which impresses the embossing pattern into the film. The embossing cylinder may be either hot or cold.
[0025] The sheeted roll may therefore have layers of adhesive sheets with alternating adhesive and embossed surfaces between the sheets.

[0026] Typically, the thermoplastic polymer and adhesive used may be biodegradable and recyclable and so the complete adhesive roll may be environmentally friendly.

[0027] Typically, the adhesive used on one side of the sheets may be any suitable adhesive which permits removal of impurities from a contaminated surface. In particular embodiments, the adhesive material may be dispensed.

[0028] The adhesive may be a pressure sensitive adhesive.

[0029] In a further embodiment, anti-static additives may be added to the film and/or the adhesive. Currently, the adhesive roll runs in contact with an elastomer roller often at high speeds. The rolling friction generates a very high static charge and the alternating layers of paper and adhesive act like a capacitor holding a charge. When an operator goes to remove one sheet from a roll to refresh it, they can in some circumstances receive a shock from the stored electricity. It has been found that the addition of anti-static agents may mitigate this risk.

[0030] The anti-static additives may, for example, be any suitable additives with anti-static properties such as ionic salts (e.g. metal salts) which may be used in a concentration of about 0.1-0.5 wt. %. Typical anti-static additives may, for example, be Larostat (Trade Mark) made by BASF and Entrina (Trade Mark) made by Du Pont.

[0031] In further embodiments, bacteriocides may be added to the adhesive and/or impregnated in the adhesive sheets to minimize the risk of bacterial growth on the adhesive roll. The adhesive roll may capture and hold bacteria and viruses from the air (e.g. swine flu) and allow the bacteria to grow and spread infection amongst the operators who remove the individual sheets to refresh the roll. Bacteriocides may be present in a concentration of about 0.1-0.5 wt.% and may, for example, be Vynzene (Trade Mark) by Rohm and Haas.

[0032] According to a second aspect of the present invention there is provided a method of removing debris and/or contaminants from a contaminated surface using a sheeted roll, said method comprising:

[0033] providing a roll core;

[0034] providing at least one sheet of adhesive material removably attached to the roll core;

[0035] wherein the adhesive sheet has two sides, a first side comprising adhesive and a second side comprising an embossed surface with the proviso that the adhesive sheet contains no silicones.

[0036] Typically, the adhesive sheet may be as described in the first aspect.

[0037] According to a third aspect of the present invention there is provided a use of a sheeted roll according to the first aspect in cleaning a contaminated surface.

[0038] According to a fourth aspect of the present invention there is provided a sheet of adhesive material which is capable of being removably attached to a roll core wherein the adhesive sheet has two sides, a first side comprising adhesive and a second side comprising an embossed surface with the proviso that the adhesive sheet contains no silicones.

[0039] The adhesive sheet may be as described in the first aspect.

[0040] According to a fifth aspect of the present invention there is provided a method of forming an embossed film suitable for contact cleaning, said method comprising:

[0041] providing an embossed cylinder; urging the embossed cylinder against a film;

[0042] wherein the film becomes embossed as the embossed cylinder is urged against the film.

[0043] According to a sixth aspect of the present invention there is provided an apparatus for cleaning a workpiece, said apparatus comprising:

[0044] at least one cleaning roll having a cleaning surface;

[0045] the cleaning roll being rotatably mountable adjacent to a workpiece;

[0046] the sheeted roll comprising at least one sheet of adhesive material removably attached thereon and being rotatably mounted adjacent the cleaning roll relative to the workpiece; wherein the adhesive sheet has two sides, a first side comprising adhesive and a second side comprising an embossed surface with the proviso that the adhesive sheet contains no silicones.

[0047] In particular embodiments, the apparatus may be used to form electronic components such as plastic electronics, photovoltaics and flat panel displays.

BRIEF DESCRIPTION OF THE DRAWINGS

[0048] Embodiments of the present invention will now be described, by way of example only, with reference to the accompanying drawings in which:

[0049] FIG. 1 is a view of apparatus for cleaning a workpiece according to an embodiment of the present invention;

[0050] FIG. 2 is a view from one end of an adhesive roll according to an embodiment of the present invention illustrating how sheets of material are superimposed onto a roll core.

BRIEF DESCRIPTION

[0051] Generally speaking, the present invention resides in the provision of an adhesive sheeted roll and layers of adhesive sheets suitable or use in contact cleaning which contain no silicones. The adhesive sheet may also comprise anti-static additives and/or bacteriocides.

[0052] FIG. 1 represents apparatus according to the present invention, generally designated 100. The apparatus 100 comprises at least one cleaning roll 112 having a cleaning surface 114. The cleaning roll 112 therefore functions as a contact cleaning roller. There is also an adhesive sheeted roll generally designated 200. The sheeted adhesive roll 200 comprises a roll core 210 which has multiple layers of adhesive sheeting. The cleaning roller 112 is typically elastomer coated or made of other forms of rubber or like material to facilitate the removal of impurities from the workpiece 110.

[0053] The cleaning roller 112 is rotatably mountable adjacent to the workpiece 110 to be cleaned in such a way that allows the cleaning surface 114 to be in contact at a point on a surface of the workpiece 110. Hence, as the workpiece 110 is conveyed, the cleaning roller 112 rotates and the cleaning surface 114 of the cleaning roller 112 removes any impurities/deposits located on the workpiece 110.

[0054] As shown in FIG. 1, the contact cleaning roller 112 counter-rotates against the adhesive sheeted roller 200 which removes contaminated particles formed on the contact cleaning roller 112. The region identified by reference 'A' in the substrate 110 is therefore uncleaned and the region identified by reference 'B' is cleaned and may then be used in the
improved manufacture of, for example, electronic components such as plastic electronics, photovoltaics and flat panel displays.

[0055] FIG. 2 is a detailed end view of the sheeted roller 200. The sheeted roller 200 comprises a roll core 210 with three individual adhesive sheets 212, 214, 216 (although any number of sheets may be used) removably attached around the circumference of the roll core 210.

[0056] The roll core 210 has an attachment means which may, for example, be an adhesive coating to allow the first individual adhesive sheet 212 to be removably attachable around the circumference of the roll core 210.

[0057] The individual adhesive sheets 212, 214, 216 have an adhesive surface 218a, 218b, 218c facing outwardly, and have a non-adhesive surface 219a, 219b, 219c facing inwardly. (Alternatively, the individual sheets can be rolled such that the adhesive surfaces are facing inwardly and the non-adhesive surfaces are facing outwardly).

[0058] The sheeted roller 200 is formed by attaching a first end 220 of the first sheet 212 onto the roll core 210 and wrapping the first sheet 212 around the circumference of the roll core 210.

[0059] The other end 222 of the first sheet 212 will overrun end 220 by virtue of the first sheet 212 being greater in length than the circumference of the roll core 210.

[0060] The end 222 is removably attached on end 220 by the adhesive surface 218a of the first sheet 212.

[0061] A second sheet 214 is then wrapped around the outer circumference of the first sheet 212 with end 224 of the second sheet 214 being abutted to end 222 of the first sheet 212. The term abutted is to be understood to include being adjacent to; there may be a gap between successive sheets.

[0062] The adhesive surface 218a of the first sheet 212 will securely hold in place the second sheet 214.

[0063] A third sheet 216 is then wrapped around the outer circumference of the second sheet 214 with end 228 of the third sheet 216 being abutted to end 226 of the second sheet 214.

[0064] The adhesive surface 218b of the second sheet 214 will securely hold in place the third sheet 216.

[0065] Similarly, further individual adhesive sheets (not shown) are abutted to end 230 of the third sheet 216 and so on until the roll core 210 is "full".

[0066] It will be realized that because the sheets 212, 214, 216 are all of the same length, the overrun or circumferential offset of the respective ends 222, 226, 230 and so on, will decrease as the roll core 210 becomes "full". The length of each sheet can however be adjusted as desired or required.

[0067] The offset of the abutment of the ends of the sheets disperses the load on the roll core 210 making the roll core 210 more stable when rotating.

[0068] In use, the roll core 210 is positioned such that the outermost sheet is positioned in contact at a point on a surface to be cleaned.

[0069] As both the roll core 210 and the cleaning roller 212 rotate, impurities located on the surface 110 to be cleaned will be transferred to the adhesive surface 218c of the outer sheet 216.

[0070] When the adhesive surface 218c of the outer sheet 216 becomes contaminated, replacement is simply achieved by peeling the contaminated sheet 216 away by virtue of lip 232, thus leaving behind a clean sheet 214 to be applied to a cleaning surface 114 of the cleaning roll 112, until that too needs replaced, and so on.

[0071] The non-adhesive surfaces 219a, 219b, 219c facing inwardly on the individual adhesive sheets 212, 214, 216 are embossed and do not have any silicones which is a particular advantage over prior art adhesive sheets. The sheeted roll 200 as a whole therefore has no silicones. The adhesive sheets 212, 214, 216 therefore have an embossed surface on the inwardly facing surface 219a, 219b, 219c. The embossing facilitates removal of the sheets 212, 214, 216 when they need to be refreshed/replaced.

[0072] In one embodiment, the adhesive sheets 212, 214, 216 are manufactured from a thermoplastic polymer such as a polypropylene film product with a molecular weight of about 150-270 kg mol⁻¹. The polypropylene film has a thickness of about 30-200 microns.

[0073] The thermoplastic polymer such as polypropylene base film and adhesives used are biodegradable and recyclable and so the complete adhesive roller 200 is environmentally friendly.

[0074] The sheets of adhesive material made from thermoplastic polymer (e.g. polypropylene) have an embossed surface to minimize the contact area of the adhesive on the film and so reduce the adhesion to a level where the adhesive roller 200 maintains its integrity but the adhesive sheets 212, 214, 216 can be unwound.

[0075] The embossing may be defined as an "orange peel" emboss which provides a random surface. The embossing is achieved using an embossing cylinder which has the embossing pattern (e.g. the "orange peel" pattern) etched on the outer surface of the cylinder. The embossing cylinder is rolled over the film which impresses the embossing pattern into the film. The embossing cylinder is either hot or cold.

[0076] The embossing is in the form of a 3-dimensional regular or irregular pattern formed on the inwardly facing surfaces 219a, 219b, 219c of the adhesive sheets 212, 214, 216. The embossing forms an imprint with a depth of about 0.2-5 microns and preferably about 1-2 microns.

[0077] The embossing on the adhesive sheet reduces the contact area of the adhesive sheets by about less than about 50%, 60%, 70%, 80% or 90%.

[0078] Anti-static additives may also be added to the film forming the adhesive sheets and/or the adhesive itself. Currently, the adhesive roller runs in contact with an elastomer roller often at high speeds. The rolling friction generates a very high static charge and the alternating layers of paper and adhesive act like a capacitor holding a charge. When an operator goes to remove one sheet from a roller to refresh it, they can in some circumstances receive a shock from the stored electricity. It has been found that the addition of anti-static agents may mitigate this risk.

[0079] The anti-static additives may, for example, be any suitable additives with anti-static properties such as ionic salts. The anti-static additives may be present in a concentration of about 0.1-0.5 wt. %. Suitable anti-static additives may be, for example, Larostat (Trade Mark) made by BASF® and Entira (Trade Mark) made by Du Pont.

[0080] Bacteriocides may also be added to the adhesive and/or impregnated into the sheets to minimize the risk of bacterial growth on the adhesive roller. The adhesive roller has the ability to capture and hold bacteria and viruses from the air (e.g. swine flu) and allow the bacteria to grow and spread infection among the operators who remove the indi-
individual sheets to refresh the roll. A particular example of a bacteriocide is Vinyzene (Trade Mark) made by Rohm and Haas. The bacteriocides are used in a concentration of about 0.1-0.5 wt. %.

10. A sheeted roll according to claim 1, wherein the adhesive sheets are biodegradable and recyclable and so the complete adhesive roll is environmentally friendly.

11. A sheeted roll according to claim 1, wherein the sheets of adhesive material and/or adhesive and/or release coating comprise anti-static additives.

12. A sheeted roll according to claim 11, wherein the anti-static additives are ionic salts used in a concentration of about 0.1-0.5 wt. %.

13. A sheeted roll according to claim 1, wherein the sheets of adhesive material and/or adhesive and/or release coating comprise bacteriocides.

14. A sheeted roll according to claim 13, wherein the bacteriocides are present in a concentration of about 0.1-0.5 wt. %.

15. A method of removing debris and/or contaminants from a contaminated surface using a sheeted roll, said method comprising:

   providing a roll core;
   providing at least one sheet of adhesive material removably attached to the core;
   wherein the adhesive sheet has two sides, a first side comprising a thermoplastic polymer with a molecular weight of about 150-270 kg mol⁻¹;
   wherein the at least one adhesive material comprises an embossed surface with the proviso that the adhesive sheet contains no silicone.

16. Apparatus for cleaning a workpiece, said apparatus comprising:

   at least one cleaning roll having a cleaning surface;
   the cleaning roll being rotatably mountable adjacent to a workpiece;
   the sheeted roll comprising at least one sheet of adhesive material removably attached to thereon and being rotatably mounted adjacent the cleaning roll relative to the workpiece; and
   wherein the at least one adhesive sheet has two sides, a first side comprising adhesive and a second side comprising an embossed surface with the proviso that the adhesive sheet contains no silicone.

17. Apparatus according to claim 16, wherein the workpiece is used to form electronic components including that of plastic electronics, photovoltaics and flat panel displays.
