THREE-DIMENSIONAL MEMORY DEVICE HAVING MULTI-LAYER DIFFUSION BARRIER STACK AND METHOD OF MAKING THEREOF

RELATED APPLICATIONS

[0001] The present application claims the benefit of priority from U.S. Non-Provisional Application Serial No. 15/215,006, filed on July 20, 2016, the entire content of which is incorporated herein by reference.

FIELD

[0002] The present disclosure relates generally to the field of semiconductor devices, and particular to a three-dimensional memory device employing a diffusion barrier liner stack and methods of manufacturing the same.

BACKGROUND

[0003] Three-dimensional vertical NAND strings having one bit per cell are disclosed in an article by T. Endoh et al., titled “Novel Ultra High Density Memory With A Stacked-Surrounding Gate Transistor (S-SGT) Structured Cell”, IEDM Proc. (2001) 33-36.

SUMMARY

[0004] According to an aspect of the present disclosure, a three-dimensional memory device is provided, which comprises: an alternating stack of insulating layers and electrically conductive layers located over a substrate; and memory stack structures extending through the alternating stack, wherein each of the memory stack structures comprises a memory film and a vertical semiconductor channel. Each of the electrically conductive layers comprises: a liner stack of a first metallic nitride liner, a tungsten liner contacting the first metallic nitride liner, and a second metallic nitride liner contacting the tungsten liner; and a metal fill portion contacting the second metallic nitride liner.

[0005] According to another aspect of the present disclosure, a method of forming a three-dimensional memory device is provided. An alternating stack of insulating layers and spacer material layers is formed over a substrate. Memory stack structures are formed through the alternating stack. Each of the memory stack structures comprises a memory film and a vertical semiconductor channel. The spacer material layers are replaced with electrically conductive layers. Each of the electrically conductive layers comprises: a liner stack of a first metallic nitride liner, a tungsten liner contacting the first metallic nitride liner, and a second metallic nitride liner contacting the tungsten liner; and a metal fill portion contacting the second metallic nitride liner.

BRIEF DESCRIPTION OF THE DRAWINGS

[0006] FIG. 1 is a schematic vertical cross-sectional view of an exemplary structure after formation of at least one peripheral device, a semiconductor material layer, and a gate dielectric layer according to an embodiment of the present disclosure.

[0007] FIG. 2 is a schematic vertical cross-sectional view of the exemplary structure after formation of an alternating stack of insulating layers and sacrificial material layers according to an embodiment of the present disclosure.

[0008] FIG. 3 is a schematic vertical cross-sectional view of the exemplary structure after formation of stepped terraces and a retro-stepped dielectric material portion according to an embodiment of the present disclosure.

[0009] FIG. 4 is a schematic vertical cross-sectional view of the exemplary structure after formation of memory openings according to an embodiment of the present disclosure.

[0010] FIGS. 5A – 5H are sequential schematic vertical cross-sectional views of a memory opening within the exemplary structure during various processing steps employed to

form a memory stack structure according to an embodiment of the present disclosure.

[0011] FIG. 6 is a schematic vertical cross-sectional view of the exemplary structure after formation of memory stack structures according to an embodiment of the present disclosure.

[0012] FIG. 7A is a schematic vertical cross-sectional view of the exemplary structure after formation of a backside trench according to an embodiment of the present disclosure.

[0013] FIG. 7B is a partial see-through top-down view of the exemplary structure of FIG. 7A. The vertical plane A – A' is the plane of the schematic vertical cross-sectional view of FIG. 7A.

[0014] FIG. 8 is a schematic vertical cross-sectional view of the exemplary structure after formation of backside recesses according to an embodiment of the present disclosure.

[0015] FIG. 9A is a magnified view of a region of the exemplary structure of FIG. 8.

[0016] FIG. 9B is a vertical cross-sectional view of the region of the exemplary structure of FIG. 9A after formation of a backside blocking dielectric layer according to an embodiment of the present disclosure.

[0017] FIG. 9C is a vertical cross-sectional view of the region of the exemplary structure of FIG. 9B after formation of a first continuous metallic nitride layer and a continuous tungsten layer according to an embodiment of the present disclosure.

[0018] FIG. 9D is a vertical cross-sectional view of the region of the exemplary structure of FIG. 9C after formation of a second continuous metallic nitride layer and a continuous metal fill layer according to an embodiment of the present disclosure.

[0019] FIG. 10 is a schematic vertical cross-sectional view of the exemplary structure at the processing step of FIG. 9D.

[0020] FIG. 11 is a schematic vertical cross-sectional view of the exemplary structure after removal of a deposited conductive material from within the backside trench according to

an embodiment of the present disclosure.

[0021] FIG. 12 is a schematic vertical cross-sectional view of the exemplary structure after formation of an insulating spacer and a backside contact structure according to an embodiment of the present disclosure.

[0022] FIG. 13 is a magnified view of a region of the exemplary structure at the processing step of FIG. 12.

[0023] FIG. 14 is a schematic vertical cross-sectional view of the exemplary structure after formation of additional contact via structures according to an embodiment of the present disclosure.

[0024] FIG. 15A is a magnified view of a region of an alternative embodiment of the exemplary structure according to an embodiment of the present disclosure.

[0025] FIG. 15B is a magnified view of a region of a second alternate embodiment of the exemplary structure according to an embodiment of the present disclosure.

[0026] FIG. 15C is a magnified view of a region of a third alternate embodiment of the exemplary structure according to an embodiment of the present disclosure.

[0027] FIG. 16 is a graph comparing distribution of ^{10}B in a reference structure employing only a titanium nitride liner and in an exemplary structure employing a TiN/W/TiN stack as a metallic liner stack according to an embodiment of the present disclosure.

[0028] FIG. 17 is a graph comparing distribution of fluorine atoms in a reference structure employing only a titanium nitride liner and in an exemplary structure employing a TiN/W/TiN stack as a metallic liner stack according to an embodiment of the present disclosure.

DETAILED DESCRIPTION

[0029] As discussed above, the present disclosure is directed to three-dimensional memory devices including a vertical stack of multilevel memory arrays and methods of making thereof, the various aspects of which are described below. The embodiments of the disclosure can be employed to form various structures including a multilevel memory structure, non-limiting examples of which include semiconductor devices such as three-dimensional monolithic memory array devices comprising a plurality of NAND memory strings. The drawings are not drawn to scale. Multiple instances of an element may be duplicated where a single instance of the element is illustrated, unless absence of duplication of elements is expressly described or clearly indicated otherwise. Ordinals such as “first,” “second,” and “third” are employed merely to identify similar elements, and different ordinals may be employed across the specification and the claims of the instant disclosure. As used herein, a first element located “on” a second element can be located on the exterior side of a surface of the second element or on the interior side of the second element. As used herein, a first element is located “directly on” a second element if there exist a physical contact between a surface of the first element and a surface of the second element.

[0030] As used herein, a “layer” refers to a material portion including a region having a thickness. A layer may extend over the entirety of an underlying or overlying structure, or may have an extent less than the extent of an underlying or overlying structure. Further, a layer may be a region of a homogeneous or inhomogeneous continuous structure that has a thickness less than the thickness of the continuous structure. For example, a layer may be located between any pair of horizontal planes between, or at, a top surface and a bottom surface of the continuous structure. A layer may extend horizontally, vertically, and/or along a tapered surface. A substrate may be a layer, may include one or more layers therein, or

may have one or more layer thereupon, thereabove, and/or therebelow.

[0031] A monolithic three-dimensional memory array is one in which multiple memory levels are formed above a single substrate, such as a semiconductor wafer, with no intervening substrates. The term “monolithic” means that layers of each level of the array are directly deposited on the layers of each underlying level of the array. In contrast, two dimensional arrays may be formed separately and then packaged together to form a non-monolithic memory device. For example, non-monolithic stacked memories have been constructed by forming memory levels on separate substrates and vertically stacking the memory levels, as described in U.S. Patent No. 5,915,167 titled “Three-dimensional Structure Memory.” The substrates may be thinned or removed from the memory levels before bonding, but as the memory levels are initially formed over separate substrates, such memories are not true monolithic three-dimensional memory arrays. The various three-dimensional memory devices of the present disclosure include a monolithic three-dimensional NAND string memory device, and can be fabricated employing the various embodiments described herein.

[0032] Referring to FIG. 1, an exemplary structure according to an embodiment of the present disclosure is illustrated, which can be employed, for example, to fabricate a device structure containing vertical NAND memory devices. The exemplary structure includes a substrate, which can be a semiconductor substrate (9, 10). The substrate can include a substrate semiconductor layer 9. The substrate semiconductor layer 9 may be a semiconductor wafer or a semiconductor material layer, and can include at least one elemental semiconductor material (e.g., single crystal silicon wafer or layer), at least one III-V compound semiconductor material, at least one II-VI compound semiconductor material, at least one organic semiconductor material, or other semiconductor materials known in the art.

The substrate can have a major surface 7, which can be, for example, a topmost surface of the substrate semiconductor layer 9. The major surface 7 can be a semiconductor surface. In one embodiment, the major surface 7 can be a single crystalline semiconductor surface, such as a single crystalline semiconductor surface.

[0033] As used herein, a “semiconducting material” refers to a material having electrical conductivity in the range from 1.0×10^{-6} S/cm to 1.0×10^5 S/cm. As used herein, a “semiconductor material” refers to a material having electrical conductivity in the range from 1.0×10^{-6} S/cm to 1.0×10^5 S/cm in the absence of electrical dopants therein, and is capable of producing a doped material having electrical conductivity in a range from 1.0 S/cm to 1.0×10^5 S/cm upon suitable doping with an electrical dopant. As used herein, an “electrical dopant” refers to a p-type dopant that adds a hole to a balance band within a band structure, or an n-type dopant that adds an electron to a conduction band within a band structure. As used herein, a “conductive material” refers to a material having electrical conductivity greater than 1.0×10^5 S/cm. As used herein, an “insulator material” or a “dielectric material” refers to a material having electrical conductivity less than 1.0×10^{-6} S/cm. As used herein, a “heavily doped semiconductor material” refers to a semiconductor material that is doped with electrical dopant at a sufficiently high atomic concentration to become a conductive material, i.e., to have electrical conductivity greater than 1.0×10^5 S/cm. A “doped semiconductor material” may be a heavily doped semiconductor material, or may be a semiconductor material that includes electrical dopants (i.e., p-type dopants and/or n-type dopants) at a concentration that provides electrical conductivity in the range from 1.0×10^{-6} S/cm to 1.0×10^5 S/cm. An “intrinsic semiconductor material” refers to a semiconductor material that is not doped with electrical dopants. Thus, a semiconductor material may be semiconducting or conductive, and may be an intrinsic semiconductor material or a doped semiconductor

material. A doped semiconductor material can be semiconducting or conductive depending on the atomic concentration of electrical dopants therein. As used herein, a “metallic material” refers to a conductive material including at least one metallic element therein. All measurements for electrical conductivities are made at the standard condition.

[0034] At least one semiconductor device 700 for a peripheral circuitry can be formed on a portion of the substrate semiconductor layer 9. The at least one semiconductor device can include, for example, field effect transistors. For example, at least one shallow trench isolation structure 120 can be formed by etching portions of the substrate semiconductor layer 9 and depositing a dielectric material therein. A gate dielectric layer, at least one gate conductor layer, and a gate cap dielectric layer can be formed over the substrate semiconductor layer 9, and can be subsequently patterned to form at least one gate structure (150, 152, 154, 158), each of which can include a gate dielectric 150, a gate electrode (152, 154), and a gate cap dielectric 158. The gate electrode (152, 154) may include a stack of a first gate electrode portion 152 and a second gate electrode portion 154. At least one gate spacer 156 can be formed around the at least one gate structure (150, 152, 154, 158) by depositing and anisotropically etching a dielectric liner. Active regions 130 can be formed in upper portions of the substrate semiconductor layer 9, for example, by introducing electrical dopants employing the at least one gate structure (150, 152, 154, 158) as masking structures. Additional masks may be employed as needed. The active region 130 can include source regions and drain regions of field effect transistors. A first dielectric liner 161 and a second dielectric liner 162 can be optionally formed. Each of the first and second dielectric liners (161, 162) can comprise a silicon oxide layer, a silicon nitride layer, and/or a dielectric metal oxide layer. As used herein, silicon oxide includes silicon dioxide as well as non-stoichiometric silicon oxides having more or less than two oxygen atoms for each silicon

atoms. Silicon dioxide is preferred. In an illustrative example, the first dielectric liner 161 can be a silicon oxide layer, and the second dielectric liner 162 can be a silicon nitride layer. The least one semiconductor device for the peripheral circuitry can contain a driver circuit for memory devices to be subsequently formed, which can include at least one NAND device.

[0035] A dielectric material such as silicon oxide can be deposited over the at least one semiconductor device, and can be subsequently planarized to form a planarization dielectric layer 170. In one embodiment the planarized top surface of the planarization dielectric layer 170 can be coplanar with a top surface of the dielectric liners (161, 162). Subsequently, the planarization dielectric layer 170 and the dielectric liners (161, 162) can be removed from an area to physically expose a top surface of the substrate semiconductor layer 9.

[0036] An optional semiconductor material layer 10 can be formed on the top surface of the substrate semiconductor layer 9 by deposition of a single crystalline semiconductor material, for example, by selective epitaxy. The deposited semiconductor material can be the same as, or can be different from, the semiconductor material of the substrate semiconductor layer 9. The deposited semiconductor material can be any material that can be employed for the semiconductor substrate layer 9 as described above. The single crystalline semiconductor material of the semiconductor material layer 10 can be in epitaxial alignment with the single crystalline structure of the substrate semiconductor layer 9. Portions of the deposited semiconductor material located above the top surface of the planarization dielectric layer 170 can be removed, for example, by chemical mechanical planarization (CMP). In this case, the semiconductor material layer 10 can have a top surface that is coplanar with the top surface of the planarization dielectric layer 170.

[0037] The region (i.e., area) of the at least one semiconductor device 700 is herein referred to as a peripheral device region 200. The region in which a memory array is

subsequently formed is herein referred to as a memory array region 100. A contact region 300 for subsequently forming stepped terraces of electrically conductive layers can be provided between the memory array region 100 and the peripheral device region 200.

Optionally, a gate dielectric layer 12 can be formed above the semiconductor material layer 10 and the planarization dielectric layer 170. The gate dielectric layer 12 can be, for example, silicon oxide layer. The thickness of the gate dielectric layer 12 can be in a range from 3 nm to 30 nm, although lesser and greater thicknesses can also be employed.

[0038] Referring to FIG. 2, a stack of an alternating plurality of first material layers (which can be insulating layers 32) and second material layers (which can be sacrificial material layer 42) is formed over the top surface of the substrate, which can be, for example, on the top surface of the gate dielectric layer 12. As used herein, a “material layer” refers to a layer including a material throughout the entirety thereof. As used herein, an alternating plurality of first elements and second elements refers to a structure in which instances of the first elements and instances of the second elements alternate. Each instance of the first elements that is not an end element of the alternating plurality is adjoined by two instances of the second elements on both sides, and each instance of the second elements that is not an end element of the alternating plurality is adjoined by two instances of the first elements on both ends. The first elements may have the same thickness thereamongst, or may have different thicknesses. The second elements may have the same thickness thereamongst, or may have different thicknesses. The alternating plurality of first material layers and second material layers may begin with an instance of the first material layers or with an instance of the second material layers, and may end with an instance of the first material layers or with an instance of the second material layers. In one embodiment, an instance of the first elements and an instance of the second elements may form a unit that is repeated with periodicity within the

alternating plurality.

[0039] Each first material layer includes a first material, and each second material layer includes a second material that is different from the first material. In one embodiment, each first material layer can be an insulating layer 32, and each second material layer can be a sacrificial material layer. In this case, the stack can include an alternating plurality of insulating layers 32 and sacrificial material layers 42, and constitutes a prototype stack of alternating layers comprising insulating layers 32 and sacrificial material layers 42. As used herein, a “prototype” structure or an “in-process” structure refers to a transient structure that is subsequently modified in the shape or composition of at least one component therein.

[0040] The stack of the alternating plurality is herein referred to as an alternating stack (32, 42). In one embodiment, the alternating stack (32, 42) can include insulating layers 32 composed of the first material, and sacrificial material layers 42 composed of a second material different from that of insulating layers 32. The first material of the insulating layers 32 can be at least one insulating material. As such, each insulating layer 32 can be an insulating material layer. Insulating materials that can be employed for the insulating layers 32 include, but are not limited to, silicon oxide (including doped or undoped silicate glass), silicon nitride, silicon oxynitride, organosilicate glass (OSG), spin-on dielectric materials, dielectric metal oxides that are commonly known as high dielectric constant (high-k) dielectric oxides (e.g., aluminum oxide, hafnium oxide, etc.) and silicates thereof, dielectric metal oxynitrides and silicates thereof, and organic insulating materials. In one embodiment, the first material of the insulating layers 32 can be silicon oxide.

[0041] The second material of the sacrificial material layers 42 is a sacrificial material that can be removed selective to the first material of the insulating layers 32. As used herein, a removal of a first material is “selective to” a second material if the removal process

removes the first material at a rate that is at least twice the rate of removal of the second material. The ratio of the rate of removal of the first material to the rate of removal of the second material is herein referred to as a “selectivity” of the removal process for the first material with respect to the second material.

[0042] The sacrificial material layers 42 may comprise an insulating material, a semiconductor material, or a conductive material. The second material of the sacrificial material layers 42 can be subsequently replaced with electrically conductive electrodes which can function, for example, as control gate electrodes of a vertical NAND device. Non-limiting examples of the second material include silicon nitride, an amorphous semiconductor material (such as amorphous silicon), and a polycrystalline semiconductor material (such as polysilicon). In one embodiment, the sacrificial material layers 42 can be spacer material layers that comprise silicon nitride or a semiconductor material including at least one of silicon and germanium.

[0043] In one embodiment, the insulating layers 32 can include silicon oxide, and sacrificial material layers can include silicon nitride sacrificial material layers. The first material of the insulating layers 32 can be deposited, for example, by chemical vapor deposition (CVD). For example, if silicon oxide is employed for the insulating layers 32, tetraethyl orthosilicate (TEOS) can be employed as the precursor material for the CVD process. The second material of the sacrificial material layers 42 can be formed, for example, CVD or atomic layer deposition (ALD).

[0044] The sacrificial material layers 42 can be suitably patterned so that conductive material portions to be subsequently formed by replacement of the sacrificial material layers 42 can function as electrically conductive electrodes, such as the control gate electrodes of the monolithic three-dimensional NAND string memory devices to be subsequently formed.

The sacrificial material layers 42 may comprise a portion having a strip shape extending substantially parallel to the major surface 7 of the substrate.

[0045] The thicknesses of the insulating layers 32 and the sacrificial material layers 42 can be in a range from 20 nm to 50 nm, although lesser and greater thicknesses can be employed for each insulating layer 32 and for each sacrificial material layer 42. The number of repetitions of the pairs of an insulating layer 32 and a sacrificial material layer (e.g., a control gate electrode or a sacrificial material layer) 42 can be in a range from 2 to 1,024, and typically from 8 to 256, although a greater number of repetitions can also be employed. The top and bottom gate electrodes in the stack may function as the select gate electrodes. In one embodiment, each sacrificial material layer 42 in the alternating stack (32, 42) can have a uniform thickness that is substantially invariant within each respective sacrificial material layer 42.

[0046] Optionally, an insulating cap layer 70 can be formed over the alternating stack (32, 42). The insulating cap layer 70 includes a dielectric material that is different from the material of the sacrificial material layers 42. In one embodiment, the insulating cap layer 70 can include a dielectric material that can be employed for the insulating layers 32 as described above. The insulating cap layer 70 can have a greater thickness than each of the insulating layers 32. The insulating cap layer 70 can be deposited, for example, by chemical vapor deposition. In one embodiment, the insulating cap layer 70 can be a silicon oxide layer.

[0047] Referring to FIG. 3, stepped terraces can be formed in the contact region 300. The stepped terraces can be formed by forming a stepped cavity within the contact region 300. The stepped cavity can have various stepped surfaces such that the horizontal cross-sectional shape of the stepped cavity changes in steps as a function of the vertical distance from the top

surface of the substrate (9, 10). In one embodiment, the stepped cavity can be formed applying and initially patterning a trimmable masking material layer, and by repetitively performing a set of processing steps. The set of processing steps can include, for example, an etch process of a first type (such as an anisotropic reactive ion etch) that vertically increases the depth of a cavity by one or more levels, and an etch process of a second type (referred to as a trimming process) that laterally expands the area to be vertically etched in a subsequent etch process of the first type. As used herein, a “level” of a structure including alternating plurality is defined as the relative position of a pair of a first material layer and a second material layer within the structure.

[0048] A dielectric material such as silicon oxide is deposited over the stepped terraces in the stepped cavity. Excess portions of the deposited dielectric material can be removed from above the top surface of the insulating cap layer 70, for example, by chemical mechanical planarization (CMP). The remaining portion of the deposited dielectric material filling the stepped cavity in the contact region 300 and the peripheral device region 200 constitutes a retro-stepped dielectric material portion 65. As used herein, a “retro-stepped” element refers to an element that has stepped surfaces and a horizontal cross-sectional area that increases monotonically as a function of a vertical distance from a top surface of a substrate on which the element is present. If silicon oxide is employed as the dielectric material, the silicon oxide of the retro-stepped dielectric material portion 65 may, or may not, be doped with dopants such as B, P, and/or F. The top surface of the retro-stepped dielectric material portion 65 can be coplanar with the top surface of the insulating cap layer 70.

[0049] Referring to FIG. 4, a lithographic material stack (not shown) including at least a photoresist layer can be formed over the insulating cap layer 70 and the retro-stepped dielectric material portion 65, and can be lithographically patterned to form openings therein.

The pattern in the lithographic material stack can be transferred through the insulating cap layer 70 and through entirety of the alternating stack (32, 42) by at least one anisotropic etch that employs the patterned lithographic material stack as an etch mask. Portions of the alternating stack (32, 42) underlying the openings in the patterned lithographic material stack are etched to form memory openings 49. In other words, the transfer of the pattern in the patterned lithographic material stack through the alternating stack (32, 42) forms the memory openings 49 that extend through the alternating stack (32, 42). The chemistry of the anisotropic etch process employed to etch through the materials of the alternating stack (32, 42) can alternate to optimize etching of the first and second materials in the alternating stack (32, 42). The anisotropic etch can be, for example, a series of reactive ion etches. The sidewalls of the memory openings 49 can be substantially vertical, or can be tapered. The patterned lithographic material stack can be subsequently removed, for example, by ashing.

[0050] The memory openings 49 are formed through the gate dielectric layer 12 so that the memory openings 49 extend from the top surface of the alternating stack (32, 42) to at least the top surface of the semiconductor material layer 10. In one embodiment, an overetch into the semiconductor material layer 10 may be optionally performed after the top surface of the semiconductor material layer 10 is physically exposed at a bottom of each memory opening 49. The overetch may be performed prior to, or after, removal of the lithographic material stack. In other words, the recessed surfaces of the semiconductor material layer 10 may be vertically offset from the undressed top surfaces of the semiconductor material layer 10 by a recess depth. The recess depth can be, for example, in a range from 1 nm to 50 nm, although lesser and greater recess depths can also be employed. The overetch is optional, and may be omitted. If the overetch is not performed, the bottom surface of each memory opening 49 can be coplanar with the topmost surface of the semiconductor material layer 10.

Each of the memory openings 49 can include a sidewall (or a plurality of sidewalls) that extends substantially perpendicular to the topmost surface of the substrate. The array of memory openings 49 is formed in the memory array region 100. The substrate semiconductor layer 9 and the semiconductor material layer 10 collectively constitutes a substrate (9, 10), which can be a semiconductor substrate. Alternatively, the semiconductor material layer 10 may be omitted, and the memory openings 49 can be extend to a top surface of the substrate semiconductor layer 9.

[0051] Referring to FIG. 5A, a memory opening 49 in the exemplary device structure of FIG. 4 is illustrated. The memory opening 49 extends through the insulating cap layer 70, the alternating stack (32, 42), an optional dielectric cap layer 31, such as a silicon oxide layer, the gate dielectric layer 12, and optionally into an upper portion of the semiconductor material layer 10. The recess depth of the bottom surface of each memory opening with respect to the top surface of the semiconductor material layer 10 can be in a range from 0 nm to 30 nm, although greater recess depths can also be employed. Optionally, the sacrificial material layers 42 can be laterally recessed partially to form lateral recesses (not shown), for example, by an isotropic etch.

[0052] Referring to FIG. 5B, an optional epitaxial channel portion (e.g., an epitaxial pedestal) 11 can be formed at the bottom portion of each memory opening 49, for example, by selective epitaxy. Each epitaxial channel portion 11 comprises a single crystalline semiconductor material in epitaxial alignment with the single crystalline semiconductor material of the semiconductor material layer 10. In one embodiment, the epitaxial channel portion 11 can be doped with electrical dopants of the same conductivity type as the semiconductor material layer 10. In one embodiment, the top surface of each epitaxial channel portion 11 can be formed above a horizontal plane including the top surface of a

sacrificial material layer 42. In this case, at least one source select gate electrode can be subsequently formed by replacing each sacrificial material layer 42 located below the horizontal plane including the top surfaces of the epitaxial channel portions 11 with a respective conductive material layer. The epitaxial channel portion 11 can be a portion of a transistor channel that extends between a source region to be subsequently formed in the substrate (9, 10) and a drain region to be subsequently formed in an upper portion of the memory opening 49. A cavity 49' is present in the unfilled portion of the memory opening 49 above the epitaxial channel portion 11. In one embodiment, the epitaxial channel portion 11 can comprise single crystalline silicon. In one embodiment, the epitaxial channel portion 11 can have a doping of the first conductivity type, which is the same as the conductivity type of the semiconductor material layer 10 that the epitaxial channel portion contacts. If a semiconductor material layer 10 is not present, the epitaxial channel portion 11 can be formed directly on the substrate semiconductor layer 9, which can have a doping of the first conductivity type.

[0053] Referring to FIG. 5C, a stack of layers including a blocking dielectric layer 52, a charge storage layer 54, a tunneling dielectric layer 56, and an optional first semiconductor channel layer 601L can be sequentially deposited in the memory openings 49.

[0054] The blocking dielectric layer 52 can include a single dielectric material layer or a stack of a plurality of dielectric material layers. In one embodiment, the blocking dielectric layer can include a dielectric metal oxide layer consisting essentially of a dielectric metal oxide. As used herein, a dielectric metal oxide refers to a dielectric material that includes at least one metallic element and at least oxygen. The dielectric metal oxide may consist essentially of the at least one metallic element and oxygen, or may consist essentially of the at least one metallic element, oxygen, and at least one non-metallic element such as nitrogen.

In one embodiment, the blocking dielectric layer 52 can include a dielectric metal oxide having a dielectric constant greater than 7.9, i.e., having a dielectric constant greater than the dielectric constant of silicon nitride.

[0055] Non-limiting examples of dielectric metal oxides include aluminum oxide (Al_2O_3), hafnium oxide (HfO_2), lanthanum oxide (LaO_2), yttrium oxide (Y_2O_3), tantalum oxide (Ta_2O_5), silicates thereof, nitrogen-doped compounds thereof, alloys thereof, and stacks thereof. The dielectric metal oxide layer can be deposited, for example, by chemical vapor deposition (CVD), atomic layer deposition (ALD), pulsed laser deposition (PLD), liquid source misted chemical deposition, or a combination thereof. The thickness of the dielectric metal oxide layer can be in a range from 1 nm to 20 nm, although lesser and greater thicknesses can also be employed. The dielectric metal oxide layer can subsequently function as a dielectric material portion that blocks leakage of stored electrical charges to control gate electrodes. In one embodiment, the blocking dielectric layer 52 includes aluminum oxide. In one embodiment, the blocking dielectric layer 52 can include multiple dielectric metal oxide layers having different material compositions.

[0056] Alternatively or additionally, the blocking dielectric layer 52 can include a dielectric semiconductor compound such as silicon oxide, silicon oxynitride, silicon nitride, or a combination thereof. In one embodiment, the blocking dielectric layer 52 can include silicon oxide. In this case, the dielectric semiconductor compound of the blocking dielectric layer 52 can be formed by a conformal deposition method such as low pressure chemical vapor deposition, atomic layer deposition, or a combination thereof. The thickness of the dielectric semiconductor compound can be in a range from 1 nm to 20 nm, although lesser and greater thicknesses can also be employed. Alternatively, the blocking dielectric layer 52 can be omitted, and a backside blocking dielectric layer can be formed after formation of

backside recesses on surfaces of memory films to be subsequently formed.

[0057] Subsequently, the charge storage layer 54 can be formed. In one embodiment, the charge storage layer 54 can be a continuous layer or patterned discrete portions of a charge trapping material including a dielectric charge trapping material, which can be, for example, silicon nitride. Alternatively, the charge storage layer 54 can include a continuous layer or patterned discrete portions of a conductive material such as doped polysilicon or a metallic material that is patterned into multiple electrically isolated portions (e.g., floating gates), for example, by being formed within lateral recesses into sacrificial material layers 42. In one embodiment, the charge storage layer 54 includes a silicon nitride layer. In one embodiment, the sacrificial material layers 42 and the insulating layers 32 can have vertically coincident sidewalls, and the charge storage layer 54 can be formed as a single continuous layer.

[0058] In another embodiment, the sacrificial material layers 42 can be laterally recessed with respect to the sidewalls of the insulating layers 32, and a combination of a deposition process and an anisotropic etch process can be employed to form the charge storage layer 54 as a plurality of memory material portions that are vertically spaced apart. While the present disclosure is described employing an embodiment in which the charge storage layer 54 is a single continuous layer, embodiments are expressly contemplated herein in which the charge storage layer 54 is replaced with a plurality of memory material portions (which can be charge trapping material portions or electrically isolated conductive material portions) that are vertically spaced apart.

[0059] The charge storage layer 54 can be formed as a single charge storage layer of homogeneous composition, or can include a stack of multiple charge storage layers. The multiple charge storage layers, if employed, can comprise a plurality of spaced-apart floating gate material layers that contain conductive materials (e.g., metal such as tungsten,

molybdenum, tantalum, titanium, platinum, ruthenium, and alloys thereof, or a metal silicide such as tungsten silicide, molybdenum silicide, tantalum silicide, titanium silicide, nickel silicide, cobalt silicide, or a combination thereof) and/or semiconductor materials (e.g., polycrystalline or amorphous semiconductor material including at least one elemental semiconductor element or at least one compound semiconductor material). Alternatively or additionally, the charge storage layer 54 may comprise an insulating charge trapping material, such as one or more silicon nitride segments. Alternatively, the charge storage layer 54 may comprise conductive nanoparticles such as metal nanoparticles, which can be, for example, ruthenium nanoparticles. The charge storage layer 54 can be formed, for example, by chemical vapor deposition (CVD), atomic layer deposition (ALD), physical vapor deposition (PVD), or any suitable deposition technique for storing electrical charges therein. The thickness of the charge storage layer 54 can be in a range from 2 nm to 20 nm, although lesser and greater thicknesses can also be employed.

[0060] The tunneling dielectric layer 56 includes a dielectric material through which charge tunneling can be performed under suitable electrical bias conditions. The charge tunneling may be performed through hot-carrier injection or by Fowler-Nordheim tunneling induced charge transfer depending on the mode of operation of the monolithic three-dimensional NAND string memory device to be formed. The tunneling dielectric layer 56 can include silicon oxide, silicon nitride, silicon oxynitride, dielectric metal oxides (such as aluminum oxide and hafnium oxide), dielectric metal oxynitride, dielectric metal silicates, alloys thereof, and/or combinations thereof. In one embodiment, the tunneling dielectric layer 56 can include a stack of a first silicon oxide layer, a silicon oxynitride layer, and a second silicon oxide layer, which is commonly known as an ONO stack. In one embodiment, the tunneling dielectric layer 56 can include a silicon oxide layer that is substantially free of

carbon or a silicon oxynitride layer that is substantially free of carbon. The thickness of the tunneling dielectric layer 56 can be in a range from 2 nm to 20 nm, although lesser and greater thicknesses can also be employed.

[0061] The optional first semiconductor channel layer 601L includes a semiconductor material such as at least one elemental semiconductor material, at least one III-V compound semiconductor material, at least one II-VI compound semiconductor material, at least one organic semiconductor material, or other semiconductor materials known in the art. In one embodiment, the first semiconductor channel layer 601L includes amorphous silicon or polysilicon. The first semiconductor channel layer 601L can be formed by a conformal deposition method such as low pressure chemical vapor deposition (LPCVD). The thickness of the first semiconductor channel layer 601L can be in a range from 2 nm to 10 nm, although lesser and greater thicknesses can also be employed. A cavity 49' is formed in the volume of each memory opening 49 that is not filled with the deposited material layers (52, 54, 56, 601L).

[0062] Referring to FIG. 5D, the optional first semiconductor channel layer 601L, the tunneling dielectric layer 56L, the charge storage layer 54, the blocking dielectric layer 52 are sequentially anisotropically etched employing at least one anisotropic etch process. The portions of the first semiconductor channel layer 601, the tunneling dielectric layer 56, the charge storage layer 54, and the blocking dielectric layer 52 located above the top surface of the insulating cap layer 70 can be removed by the at least one anisotropic etch process. Further, the horizontal portions of the first semiconductor channel layer 601L, the tunneling dielectric layer 56, the charge storage layer 54, and the blocking dielectric layer 52 at a bottom of each cavity 49' can be removed to form openings in remaining portions thereof. Each of the first semiconductor channel layer 601L, the tunneling dielectric layer 56, the

charge storage layer 54, and the blocking dielectric layer 52 can be etched by anisotropic etch process.

[0063] Each remaining portion of the first semiconductor channel layer 601L constitutes a first semiconductor channel portion 601. The charge storage layer 54 can comprise a charge trapping material or a floating gate material. In one embodiment, each charge storage layer 54 can include a vertical stack of charge storage regions that store electrical charges upon programming. In one embodiment, the charge storage layer 54 can be a charge storage layer in which each portion adjacent to the sacrificial material layers 42 constitutes a charge storage region.

[0064] A surface of the epitaxial channel portion 11 (or a surface of the semiconductor substrate layer 10 in case the epitaxial channel portions 11 are not employed) can be physically exposed underneath the opening through the first semiconductor channel portion 601, the tunneling dielectric layer 56, the charge storage layer 54, and the blocking dielectric layer 52. Optionally, the physically exposed semiconductor surface at the bottom of each cavity 49' can be vertically recessed so that the recessed semiconductor surface underneath the cavity 49' is vertically offset from the topmost surface of the epitaxial channel portion 11 (or of the semiconductor substrate layer 10 in case epitaxial channel portions 11 are not employed) by a recess distance. A tunneling dielectric layer 56 is located over the charge storage layer 54. A set of a blocking dielectric layer 52, a charge storage layer 54, and a tunneling dielectric layer 56 in a memory opening 49 constitutes a memory film 50, which includes a plurality of charge storage regions (as embodied as the charge storage layer 54) that are insulated from surrounding materials by the blocking dielectric layer 52 and the tunneling dielectric layer 56. In one embodiment, the first semiconductor channel portion 601, the tunneling dielectric layer 56, the charge storage layer 54, and the blocking dielectric

layer 52 can have vertically coincident sidewalls.

[0065] Referring to FIG. 5E, a second semiconductor channel layer 602L can be deposited directly on the semiconductor surface of the epitaxial channel portion 11 or the semiconductor substrate layer 10 if portion 11 is omitted, and directly on the first semiconductor channel portion 601. The second semiconductor channel layer 602L includes a semiconductor material such as at least one elemental semiconductor material, at least one III-V compound semiconductor material, at least one II-VI compound semiconductor material, at least one organic semiconductor material, or other semiconductor materials known in the art. In one embodiment, the second semiconductor channel layer 602L includes amorphous silicon or polysilicon. The second semiconductor channel layer 602L can be formed by a conformal deposition method such as low pressure chemical vapor deposition (LPCVD). The thickness of the second semiconductor channel layer 602L can be in a range from 2 nm to 10 nm, although lesser and greater thicknesses can also be employed. The second semiconductor channel layer 602L may partially fill the cavity 49' in each memory opening, or may fully fill the cavity in each memory opening.

[0066] The materials of the first semiconductor channel portion 601 and the second semiconductor channel layer 602L are collectively referred to as a semiconductor channel material. In other words, the semiconductor channel material is a set of all semiconductor material in the first semiconductor channel portion 601 and the second semiconductor channel layer 602L.

[0067] Referring to FIG. 5F, in case the cavity 49' in each memory opening is not completely filled by the second semiconductor channel layer 602L, a dielectric core layer 62L can be deposited in the cavity 49' to fill any remaining portion of the cavity 49' within each memory opening. The dielectric core layer 62L includes a dielectric material such as

silicon oxide or organosilicate glass. The dielectric core layer 62L can be deposited by a conformal deposition method such as low pressure chemical vapor deposition (LPCVD), or by a self-planarizing deposition process such as spin coating.

[0068] Referring to FIG. 5G, the horizontal portion of the dielectric core layer 62L can be removed, for example, by a recess etch from above the top surface of the insulating cap layer 70. Each remaining portion of the dielectric core layer 62L constitutes a dielectric core 62. Further, the horizontal portion of the second semiconductor channel layer 602L located above the top surface of the insulating cap layer 70 can be removed by a planarization process, which can employ a recess etch or chemical mechanical planarization (CMP). Each remaining portion of the second semiconductor channel layer 602L within a memory opening constitutes a second semiconductor channel portion 602.

[0069] Each adjoining pair of a first semiconductor channel portion 601 and a second semiconductor channel portion 602 can collectively form a semiconductor channel 60 through which electrical current can flow when a vertical NAND device including the semiconductor channel 60 is turned on. A tunneling dielectric layer 56 is surrounded by a charge storage layer 54, and laterally surrounds a portion of the semiconductor channel 60. Each adjoining set of a blocking dielectric layer 52, a charge storage layer 54, and a tunneling dielectric layer 56 collectively constitute a memory film 50, which can store electrical charges with a macroscopic retention time. In some embodiments, a blocking dielectric layer 52 may not be present in the memory film 50 at this step, and a blocking dielectric layer may be subsequently formed after formation of backside recesses. As used herein, a macroscopic retention time refers to a retention time suitable for operation of a memory device as a permanent memory device such as a retention time in excess of 24 hours.

[0070] Referring to FIG. 5H, the top surface of each dielectric core 62 can be further

recessed within each memory opening, for example, by a recess etch to a depth that is located between the top surface of the insulating cap layer 70 and the bottom surface of the insulating cap layer 70. Drain regions 63 can be formed by depositing a doped semiconductor material within each recessed region above the dielectric cores 62. The doped semiconductor material can be, for example, doped polysilicon. Excess portions of the deposited semiconductor material can be removed from above the top surface of the insulating cap layer 70, for example, by chemical mechanical planarization (CMP) or a recess etch to form the drain regions 63.

[0071] The exemplary memory stack structure 55 can be embedded into the exemplary structure illustrated in FIG. 4. FIG. 6 illustrates the exemplary structure that incorporates multiple instances of the exemplary memory stack structure of FIG. 5H. Each exemplary memory stack structure 55 includes a semiconductor channel 60 which may comprise layers (601, 602) and a memory film 50. The memory film 50 may comprise a tunneling dielectric layer 56 laterally surrounding the semiconductor channel 60 and a vertical stack of charge storage regions laterally surrounding the tunneling dielectric layer 56 (as embodied as a memory material layer 54) and an optional blocking dielectric layer 52. The exemplary structure includes a semiconductor device, which comprises a stack (32, 42) including an alternating plurality of material layers (e.g., the sacrificial material layers 42) and insulating layers 32 located over a semiconductor substrate (e.g., over the semiconductor material layer 10), and a memory opening extending through the stack (32, 42). The semiconductor device further comprises a blocking dielectric layer 52 vertically extending from a bottommost layer (e.g., the bottommost sacrificial material layer 42) of the stack to a topmost layer (e.g., the topmost sacrificial material layer 42) of the stack, and contacting a sidewall of the memory opening and a horizontal surface of the semiconductor substrate. While the present

disclosure is described employing the illustrated configuration for the memory stack structure, the methods of the present disclosure can be applied to alternative memory stack structures including a polycrystalline semiconductor channel.

[0072] Referring to FIGS. 7A and 7B, at least one support pillar 7P may be optionally formed through the retro-stepped dielectric material portion 65 and/or through the insulating cap layer 70 and/or through the alternating stack (32, 42). The plane A – A' in FIG. 7B corresponds to the plane of the schematic vertical cross-sectional view of FIG. 7A. In one embodiment, the at least one support pillar 7P can be formed in the contact region 300, which is located adjacent to the memory array region 100. The at least one support pillar 7P can be formed, for example, by forming an opening extending through the retro-stepped dielectric material portion 65 and/or through the alternating stack (32, 42) and at least to the top surface of the substrate (9, 10), and by filling the opening with a material that is resistant to the etch chemistry to be employed to remove the sacrificial material layers 42.

[0073] In one embodiment, the at least one support pillar 7P comprises a dummy memory stack structure which contains the memory film 50, semiconductor channel 60 and core dielectric 62 which are formed at the same time as the memory stack structures 55. However, the dummy memory stack structures 7P are not electrically connected to bit lines and are used as support pillars rather than as NAND strings. In another embodiment, the at least one support pillar 7P can include an insulating material, such as silicon oxide and/or a dielectric metal oxide such as aluminum oxide.

[0074] In another embodiment, the at least one support pillar can include a dielectric material, such as silicon oxide and/or a dielectric metal oxide such as aluminum oxide. In one embodiment, the portion of the dielectric material that is deposited over the insulating cap layer 70 concurrently with deposition of the at least one support pillar 7P can be present

over the insulating cap layer 70 as a contact level dielectric layer 73. Each of the at least one support pillar 7P and the contact level dielectric layer 73 is an optional structure. As such, the contact level dielectric layer 73 may, or may not, be present over the insulating cap layer 70 and the retro-stepped dielectric material portion 65. Alternatively, formation of the contact level dielectric layer 73 may be omitted, and at least one via level dielectric layer may be subsequently formed, i.e., after formation of a backside contact via structure. The contact level dielectric layer 73 and the at least one support pillar 7P can be formed as a single continuous structure of integral construction, i.e., without any material interface therebetween. In another embodiment, the portion of the dielectric material that is deposited over the insulating cap layer 70 concurrently with deposition of the at least one support pillar 7P can be removed, for example, by chemical mechanical planarization or a recess etch. In this case, the contact level dielectric layer 73 is not present, and the top surface of the insulating cap layer 70 can be physically exposed.

[0075] A photoresist layer (not shown) can be applied over the alternating stack (32, 42), and is lithographically patterned to form at least one elongated opening in each area in which formation of a backside contact via structure is desired. The pattern in the photoresist layer can be transferred through the alternating stack (32, 42) and/or the retro-stepped dielectric material portion 65 employing an anisotropic etch to form the at least one backside trench 79, which extends at least to the top surface of the substrate (9, 10). In one embodiment, the at least one backside trench 79 can include a source contact opening in which a source contact via structure can be subsequently formed.

[0076] Referring to FIGS. 8 and 9A, an etchant that selectively etches the second material of the sacrificial material layers 42 with respect to the first material of the insulating layers 32 can be introduced into the at least one backside trench 79, for example, employing an etch

process. Backside recesses 43 are formed in volumes from which the sacrificial material layers 42 are removed. The removal of the second material of the sacrificial material layers 42 can be selective to the first material of the insulating layers 32, the material of the at least one support pillar 7P, the material of the retro-stepped dielectric material portion 65, the semiconductor material of the semiconductor material layer 10, and the material of the outermost layer of the memory films 50. In one embodiment, the sacrificial material layers 42 can include silicon nitride, and the materials of the insulating layers 32, the at least one support pillar 7P, and the retro-stepped dielectric material portion 65 can be selected from silicon oxide and dielectric metal oxides. In another embodiment, the sacrificial material layers 42 can include a semiconductor material such as polysilicon, and the materials of the insulating layers 32, the at least one support pillar 7P, and the retro-stepped dielectric material portion 65 can be selected from silicon oxide, silicon nitride, and dielectric metal oxides. In this case, the depth of the at least one backside trench 79 can be modified so that the bottommost surface of the at least one backside trench 79 is located within the gate dielectric layer 12, i.e., to avoid physical exposure of the top surface of the semiconductor material layer 10.

[0077] The etch process that removes the second material selective to the first material and the outermost layer of the memory films 50 can be a wet etch process employing a wet etch solution, or can be a gas phase (dry) etch process in which the etchant is introduced in a vapor phase into the at least one backside trench 79. For example, if the sacrificial material layers 42 include silicon nitride, the etch process can be a wet etch process in which the exemplary structure is immersed within a wet etch tank including phosphoric acid, which etches silicon nitride selective to silicon oxide, silicon, and various other materials employed in the art. The at least one support pillar 7P, the retro-stepped dielectric material portion 65,

and the memory stack structures 55 provide structural support while the backside recesses 43 are present within volumes previously occupied by the sacrificial material layers 42.

[0078] Each backside recess 43 can be a laterally extending cavity having a lateral dimension that is greater than the vertical extent of the cavity. In other words, the lateral dimension of each backside recess 43 can be greater than the height of the backside recess 43. A plurality of backside recesses 43 can be formed in the volumes from which the second material of the sacrificial material layers 42 is removed. The memory openings in which the memory stack structures 55 are formed are herein referred to as front side openings or front side cavities in contrast with the backside recesses 43. In one embodiment, the memory array region 100 comprises an array of monolithic three-dimensional NAND strings having a plurality of device levels disposed above the substrate (9, 10). In this case, each backside recess 43 can define a space for receiving a respective word line of the array of monolithic three-dimensional NAND strings.

[0079] Each of the plurality of backside recesses 43 can extend substantially parallel to the top surface of the substrate (9, 10). A backside recess 43 can be vertically bounded by a top surface of an underlying insulating layer 32 and a bottom surface of an overlying insulating layer 32. In one embodiment, each backside recess 43 can have a uniform height throughout.

[0080] Physically exposed surface portions of the optional epitaxial channel portions 11 and the semiconductor material layer 10 can be converted into dielectric material portions by thermal conversion and/or plasma conversion of the semiconductor materials into dielectric materials. For example, thermal conversion and/or plasma conversion can be employed to convert a surface portion of each epitaxial channel portion 11 into a tubular dielectric spacer 116, and to convert each physically exposed surface portion of the semiconductor material

layer 10 into a planar dielectric portion 616. In one embodiment, each tubular dielectric spacer 116 can be topologically homeomorphic to a torus, i.e., generally ring-shaped. As used herein, an element is topologically homeomorphic to a torus if the shape of the element can be continuously stretched without destroying a hole or forming a new hole into the shape of a torus. The tubular dielectric spacers 116 include a dielectric material that includes the same semiconductor element as the epitaxial channel portions 11 and additionally includes at least one non-metallic element such as oxygen and/or nitrogen such that the material of the tubular dielectric spacers 116 is a dielectric material. In one embodiment, the tubular dielectric spacers 116 can include a dielectric oxide, a dielectric nitride, or a dielectric oxynitride of the semiconductor material of the epitaxial channel portions 11. Likewise, each planar dielectric portion 616 includes a dielectric material that includes the same semiconductor element as the semiconductor material layer and additionally includes at least one non-metallic element such as oxygen and/or nitrogen such that the material of the planar dielectric portions 616 is a dielectric material. In one embodiment, the planar dielectric portions 616 can include a dielectric oxide, a dielectric nitride, or a dielectric oxynitride of the semiconductor material of the semiconductor material layer 10.

[0081] Referring to FIG. 9B, a backside blocking dielectric layer 44 can be optionally formed. The backside blocking dielectric layer 44, if present, comprises a dielectric material that functions as a control gate dielectric for the control gates to be subsequently formed in the backside recesses 43. In case the blocking dielectric layer 52 is present within each memory opening, the backside blocking dielectric layer is optional. In case the blocking dielectric layer 52 is omitted, the backside blocking dielectric layer is present.

[0082] The backside blocking dielectric layer 44 can be formed in the backside recesses 43 and on a sidewall of the backside trench 79. The backside blocking dielectric layer 43 can

be formed directly on horizontal surfaces of the insulating layers 32 and sidewalls of the memory stack structures 55 within the backside recesses 43. If the backside blocking dielectric layer 44 is formed, formation of the tubular dielectric spacers 116 and the planar dielectric portion 616 prior to formation of the backside blocking dielectric layer 44 is optional. In one embodiment, the backside blocking dielectric layer 44 can be formed by a conformal deposition process such as atomic layer deposition (ALD). The backside blocking dielectric layer 44 can consist essentially of aluminum oxide. The thickness of the backside blocking dielectric layer 44 can be in a range from 1 nm to 15 nm, such as 2 to 6 nm, although lesser and greater thicknesses can also be employed.

[0083] The dielectric material of the backside blocking dielectric layer 44 can be a dielectric metal oxide such as aluminum oxide, a dielectric oxide of at least one transition metal element, a dielectric oxide of at least one Lanthanide element, a dielectric oxide of a combination of aluminum, at least one transition metal element, and/or at least one Lanthanide element. Alternatively or additionally, the backside blocking dielectric layer can include a silicon oxide layer. The backside blocking dielectric layer can be deposited by a conformal deposition method such as chemical vapor deposition or atomic layer deposition. The thickness of the backside blocking dielectric layer can be in a range from 1 nm to 10 nm, although lesser and greater thicknesses can also be employed. The backside blocking dielectric layer is formed on the sidewalls of the at least one backside trench 79, horizontal surfaces and sidewalls of the insulating layers 32, the portions of the sidewall surfaces of the memory stack structures 55 that are physically exposed to the backside recesses 43, and a top surface of the planar dielectric portion 616. A backside cavity 79' is present within the portion of each backside trench 79 that is not filled with the backside blocking dielectric layer.

[0084] Subsequently, a continuous layer stack including multiple continuous conductive layers is formed in the backside recesses. The continuous layer stack of the multiple continuous conductive layers can include a plurality of metallic liner layer.

[0085] Referring to FIG. 9C, a first continuous metallic nitride layer 462L can be deposited directly on the surfaces of the backside blocking dielectric layer 44 according to an embodiment of the present disclosure. The first continuous metallic nitride layer 462L includes a metallic nitride material such as TiN, TaN, WN, an alloy thereof, or a stack thereof. The first continuous metallic nitride layer 462L functions as a diffusion barrier layer and an adhesion promotion layer. The first continuous metallic nitride layer 462L can have a thickness in a range from 1 nm to 6 nm (such as from 1 nm to 3 nm), although lesser and greater thicknesses can also be employed. Generally, the resistivity of a metallic nitride material is greater than the resistivity of pure metals such as W, Cu, Al, Co, Au, etc. The thickness of the first continuous metallic nitride layer 462L is limited due to the finite height of the backside recesses 43 and the need to provide a high conductive material (such as an elemental metal or an intermetallic alloy) within a predominant volume of each backside recess 43 to provide a low conductivity conductive structure.

[0086] The first continuous metallic nitride layer 462L can be deposited by a conformal deposition method such as chemical vapor deposition (CVD) or atomic layer deposition (ALD). The first continuous metallic nitride layer 462L can be deposited as a continuous material layer overlying sidewalls of the memory stack structures 55 and contacting vertical and horizontal sidewalls of the backside blocking dielectric layer 44 in the backside recesses 43 and in each backside trench 79 and overlying the contact level dielectric layer 73. In case the optional backside blocking dielectric layer 44 is not employed, the continuous metallic nitride layer 462 can be deposited directly on sidewalls of the memory stack structures 55,

horizontal surfaces and sidewalls of the insulating layer 32, on the top surface of each tubular dielectric spacer 116 and each planar dielectric portion 616, and the top surface of the contact level dielectric layer 73. A backside cavity 79' is present within each backside trench 79.

[0087] Subsequently, a continuous tungsten layer 464L can be deposited directly on the first continuous metallic nitride layer 462L by a conformal deposition method such as chemical vapor deposition or atomic layer deposition. In one embodiment, the continuous tungsten layer 464L can be formed employing WF_6 and a hydride of an element such as SiH_4 , Si_2H_6 , Ge_2H_6 , or B_2H_6 . An alternate tungsten-containing source gas for tungsten may also be employed in lieu of WF_6 . Non-limiting exemplary alternative tungsten-containing source gases include WCl_6 , $W(CH_3)_6$, tungsten carbonyl, $WCl_2(Nt-Bu)_2py_2$, $W(Nt-Bu)_2Cl\{(Ni-Pr)_2CNi-Pr_2\}$, $W(Nt-Bu)_2Cl\{(Ni-Pr)_2CNMe_2\}$, $W(Nt-Bu)_2Cl\{(Ni-Pr)_2CNEt_2\}$, $W(Nt-Bu)_2Cl\{(NCy)_2CNEt_2\}$, $W(Nt-Bu)_2NMe_2\{(Ni-Pr)_2CNi-Pr_2\}$, $W(Nt-Bu)_2(NMe_2)\{(Ni-Pr)_2CNMe_2\}$, $W(Nt-Bu)_2(N_3)\{(Ni-Pr)_2CNi-Pr_2\}$, $W(Nt-Bu)_2\{(Ni-Pr)_2CNMe_2\}$, $[W(Nt-Bu)_2Cl\{NC(NMe_2)_2\}]_2$, $W(Nt-Bu)_2(N_3)\{NC(NMe_2)_2\}_2$, and $[(W(Nt-Bu)_2(N_3)(\mu_2-N_3)py)]_2$.

[0088] The duration (e.g., for CVD), or the number of cycles (e.g. for ALD), in the deposition process for the continuous tungsten layer 464L may be selected such that the thickness of the continuous tungsten layer 464L can be in a range from 1 nm to 6 nm (such as from 1 nm to 3 nm), although lesser and greater thicknesses can also be employed. The continuous tungsten layer 464L can be formed with a uniform thickness throughout on the surfaces of the first continuous metallic nitride layer 462L in the backside recesses 43 and the backside trench 79, and above the contact level dielectric layer 73.

[0089] Referring to FIGS. 9D and 10, a second continuous metallic nitride layer 466L can be deposited directly on the surfaces of the continuous tungsten layer 464L according to an embodiment of the present disclosure. The second continuous metallic nitride layer 466L

includes a metallic nitride material such as TiN, TaN, WN, an alloy thereof, or a stack thereof. The second continuous metallic nitride layer 466L functions as another diffusion barrier layer in addition to the first continuous metallic nitride layer 462L. The second continuous metallic nitride layer 466L can have a thickness in a range from 1 nm to 6 nm (such as from 1 nm to 3 nm), although lesser and greater thicknesses can also be employed. The thickness of the second continuous metallic nitride layer 466L is limited due to the finite height of the backside recesses 43 and the need to provide a high conductive material within a predominant volume of each backside recess 43 to provide a low conductivity conductive structure.

[0090] The second continuous metallic nitride layer 466L can be deposited by a conformal deposition method such as chemical vapor deposition (CVD) or atomic layer deposition (ALD). The second continuous metallic nitride layer 466L can be deposited as a continuous material layer over the sidewalls and horizontal surfaces of the continuous tungsten layer 464L in the backside recesses 43 and in each backside trench 79 and over the contact level dielectric layer 73.

[0091] Subsequently, a continuous metal fill layer 468L can be deposited directly on the second continuous metallic nitride layer 466L by a conformal deposition method such as chemical vapor deposition or atomic layer deposition. In this case, the second continuous metallic nitride layer 466L can function as an adhesion promotion layer so that the continuous metal fill layer 468L adheres to the second continuous metallic nitride layer 466L. Alternatively, the continuous metal fill layer 468L can be deposited by electroplating or electroless plating. In this case, the material of the second continuous metallic nitride layer 466L can function as a seed layer for the electroplating process or the electroless plating process. In one embodiment, the continuous metal fill layer 468L can be deposited to fill

remaining volumes of the backside recesses 43, while not completely filling the at least one backside trench 79.

[0092] The continuous metal fill layer 468L includes at least one elemental metal portion, which can be a single elemental metal portion or a combination of at least two elemental metal portions. For example, the continuous metal fill layer 468L can include at least one elemental metal portion including an elemental metal selected from W, Cu, Co, Mo, Ru, Au, and Ag. Additionally or alternatively, the continuous metal fill layer 468L can include at least one intermetallic metal alloy portion. Each of the at least one intermetallic metal alloy portion can include at least two metal elements selected from W, Cu, Co, Mo, Ru, Au, Ag, Pt, Ni, Ti, and Ta. In one embodiment, the continuous metal fill layer 468L can consist essentially of W, Co, Mo, or Ru. In one embodiment, the continuous metal fill layer 468L can consist essentially of a metal selected from elemental tungsten, elemental molybdenum, elemental cobalt, elemental copper, elemental ruthenium, and an intermetallic alloy thereof.

[0093] In an embodiment, the first continuous metallic nitride layer 462L comprises titanium nitride, the second continuous metallic nitride layer 466L comprises titanium nitride, and the continuous metal fill layer 468 comprises tungsten. The continuous metal fill layer 468 may comprise a seed layer portion formed employing WF_6 and a hydride of an element such as SiH_4 , Si_2H_6 , Ge_2H_6 , or B_2H_6 which is used to reduce WF_6 , and a bulk portion formed on the seed layer employing WF_6 and H_2 which is used to reduce WF_6 . The seed layer portion includes fluorine and optionally boron (i.e., if B_2H_6 is used to reduce WF_6) and the bulk portion includes fluorine. The multi-layer liner stack comprising the TiN, W and TiN layers (462, 464, 466) acts as a diffusion barrier to decrease the amount of fluorine and/or boron which is diffused into the memory film 50 and the insulating layers 32.

[0094] The first continuous metallic nitride layer 462L, the continuous tungsten layer

464L, the second continuous metallic nitride layer 466L, and the continuous metal fill layer 468L forms a continuous layer stack (462L, 464L, 466L, 468L). If the backside blocking dielectric layer 44 is present, the continuous layer stack (462L, 464L, 466L, 468L) is formed directly on surfaces of the backside blocking dielectric layer 44. If the backside blocking dielectric layer 44 is not present, the continuous layer stack (462L, 464L, 466L, 468L) can be formed directly on sidewalls of the memory stack structures 55, horizontal surfaces of the insulating layers 32, sidewalls of the insulating layers 32, and on the top surface of the contact level dielectric layer 73. In one embodiment, each of the first continuous metallic nitride layer 462L, the continuous tungsten layer 464L, and the second continuous metallic nitride layer 466L can be formed by a respective conformal deposition process with a respective uniform thickness throughout.

[0095] Each portion of the continuous layer stack (462L, 464L, 466L, 468L) located in a backside recess constitutes an electrically conductive layer 46. The portion of the continuous layer stack (462L, 464L, 466L, 468L) that exclude the electrically conductive layers 46 constitute continuous metallic material layer 46L. A plurality of electrically conductive layers 46 can be formed in the plurality of backside recesses 43, and the continuous metallic material layer 46L can be formed on the sidewalls of each backside trench 79 and over the contact level dielectric layer 73. Thus, each sacrificial material layer 42 can be replaced with an electrically conductive layer 46. A backside cavity 79' is present in the portion of each backside trench 79 that is not filled with the backside blocking dielectric layer and the continuous metallic material layer 46L. A tubular dielectric spacer 116 laterally surrounds a semiconductor portion that underlies the lower doped semiconductor portion (e.g., portion 11), wherein one of the electrically conductive layers laterally surrounds the tubular dielectric spacer upon formation of the electrically conductive layers.

[0096] Referring to FIG. 11, the deposited metallic material of the continuous electrically conductive material layer 46L is etched back from the sidewalls of each backside trench 79 and from above the contact level dielectric layer 73, for example, by an isotropic wet etch, an anisotropic dry etch, or a combination thereof. The electrically conductive layers 46 in the backside recesses are not removed by the etch process. In one embodiment, the sidewalls of the various layers in each electrically conductive layer 46 which are exposed in the backside trench 79 can be vertically coincident after removal of the continuous electrically conductive material layer 46L. In this case, each metal fill portion 468 can include a sidewall that is vertically coincident with the vertically coincident sidewalls of the first metallic nitride liner 462, the tungsten liner 464, and the second metallic nitride liner 466 within the same electrically conductive layer 46. Each electrically conductive layer 46 can be a conductive line structure. Thus, the sacrificial material layers 42 are replaced with the electrically conductive layers 46.

[0097] Each electrically conductive layer 46 can function as a combination of a plurality of control gate electrodes located at a same level and a word line electrically interconnecting, i.e., electrically shorting, the plurality of control gate electrodes located at the same level. The plurality of control gate electrodes within each electrically conductive layer 46 are the control gate electrodes for the vertical memory devices including the memory stack structures 55. In other words, each electrically conductive layer 46 can be a word line that functions as a common control gate electrode for the plurality of vertical memory devices.

[0098] Referring to FIGS. 12 and 13, an insulating material layer can be formed in the at least one backside trench 79 and over the contact level dielectric layer 73 by a conformal deposition process. Exemplary conformal deposition processes include, but are not limited to, chemical vapor deposition and atomic layer deposition. The insulating material layer

includes an insulating material such as silicon oxide, silicon nitride, a dielectric metal oxide, an organosilicate glass, or a combination thereof. In one embodiment, the insulating material layer can include silicon oxide. The insulating material layer can be formed, for example, by low pressure chemical vapor deposition (LPCVD) or atomic layer deposition (ALD). The thickness of the insulating material layer can be in a range from 1.5 nm to 60 nm, although lesser and greater thicknesses can also be employed. An anisotropic etch is performed to remove horizontal portions of the insulating material layer from above the contact level dielectric layer 73 and at the bottom of each backside trench 79. Each remaining portion of the insulating material layer constitutes an insulating spacer 74. The anisotropic etch can continue to etch through physically exposed portions of the planar dielectric portion 616 in each backside trench 79. Each remaining portion of the planar dielectric portion 616 is herein referred to as an annular insulating spacer 616'. Thus, an insulating spacer 74 is formed in each backside trench 79 directly on physically exposed sidewalls of the electrically conductive layers 46.

[0099] A source region 61 can be formed underneath each backside trench 79 by implantation of electrical dopants into physically exposed surface portions of the semiconductor material layer 10. Each source region 61 is formed in a surface portion of the substrate (9, 10) that underlies a respective opening through the insulating spacer 74. Due to the straggle of the implanted dopant atoms during the implantation process and lateral diffusion of the implanted dopant atoms during a subsequent activation anneal process, each source region 61 can contact a bottom surface of the insulating spacer 74.

[0100] A backside contact via structure 76 can be formed within each cavity 79'. Each contact via structure 76 can fill a respective cavity 79'. The backside contact via structures 76 can be formed by depositing at least one conductive material in the remaining unfilled

volume (i.e., the backside cavity 79') of the backside trench 79. For example, the at least one conductive material can include a conductive liner 76A and a conductive fill material portion 76B. The conductive liner 76A can include a metallic liner such as TiN, TaN, WN, TiC, TaC, WC, an alloy thereof, or a stack thereof. The thickness of the conductive liner 76A can be in a range from 3 nm to 30 nm, although lesser and greater thicknesses can also be employed. The conductive fill material portion 76B can include a metal or a metallic alloy. For example, the conductive fill material portion 76B can include W, Cu, Al, Co, Ru, Ni, an alloy thereof, or a stack thereof. The at least one conductive material can be planarized employing the contact level dielectric layer 73 overlying the alternating stack (32, 46) as a stopping layer. If chemical mechanical planarization (CMP) process is employed, the contact level dielectric layer 73 can be employed as a CMP stopping layer. Each remaining continuous portion of the at least one conductive material in the backside trenches 79 constitutes a backside contact via structure 76. Each backside contact via structure 76 can be formed directly on a top surface of a source region 61. Each backside contact via structure 76 can contact a respective source region 61, and can be laterally surrounded by a respective insulating spacer 74.

[0101] Between each pair of an insulating spacer 74 and a memory stack structure 55, each patterned portion of the first continuous metallic nitride layer 462L constitutes a first metallic nitride liner 462, each patterned portion of the continuous tungsten layer 464L constitutes a tungsten liner 464, each patterned portion of the second continuous metallic nitride layer 466L constitutes a second metallic nitride liner 466, and each patterned portion of the continuous metal fill layer 468L constitutes a metal fill portion 468. Each combination of a first metallic nitride liner 462, a tungsten liner 464, and a second metallic nitride liner 466 within a same electrically conductive layer 46 constitutes a liner stack (462, 464, 466).

Each liner stack (462, 464, 466) includes a first metallic nitride liner 462, a tungsten liner 464 contacting the first metallic nitride liner 462, and a second metallic nitride liner 466 contacting the tungsten liner 464. Each of the electrically conductive layers 46 comprises a liner stack (462, 464, 466) and a metal fill portion 468 contacting the second metallic nitride liner 466 within the liner stack (462, 464, 466). The metal fill portion 468 is surrounded on three sides by the liner stack (462, 464, 466) within the same electrically conductive layer 46. A metal fill portion 468 can be vertically spaced from neighboring insulating layers 32 by horizontal portions of the liner stack (462, 464, 466) within the same electrically conductive layer 46, and can be laterally spaced from a memory stack structure 55 by a vertical portion of the liner stack (462, 464, 466) within the same electrically conductive layer 46.

[0102] Within each electrically conductive layer 46, the second metallic nitride liner 466 can comprise an upper horizontal second metallic nitride portion contacting a top surface of a respective metal fill portion 468, a lower horizontal second metallic nitride portion contacting a bottom surface of the respective metal fill portion 468, and a vertical second metallic nitride portion contacting a sidewall of the respective metal fill portion 468. The tungsten liner 464 comprises an upper horizontal tungsten portion contacting a top surface of a respective upper horizontal second metallic nitride portion, a lower horizontal tungsten portion contacting a bottom surface of a respective lower horizontal second metallic nitride portion, and a vertical tungsten portion contacting a sidewall of a respective vertical second metallic nitride portion. The first metallic nitride liner 462 comprises an upper horizontal first metallic nitride portion contacting a top surface of a respective upper horizontal tungsten portion, a lower horizontal first metallic nitride portion contacting a bottom surface of a respective lower horizontal tungsten portion, and a vertical first metallic nitride portion contacting a sidewall of a respective vertical tungsten portion.

[0103] In one embodiment, each metal fill portion 468 can consist essentially of a metal selected from elemental tungsten, elemental molybdenum, elemental cobalt, elemental copper, elemental ruthenium, and an intermetallic alloy thereof. In one embodiment, the metal fill portion 468 comprises tungsten and the liner stack (462, 464, 466) comprises a TiN/W/TiN stack.

[0104] Referring to FIG. 14, additional contact via structures (88, 86, 8A, 8G) can be formed through the contact level dielectric layer 73, and optionally through the retro-stepped dielectric material portion 65. For example, drain contact via structures 88 can be formed through the contact level dielectric layer 73 on each drain region 63. Word line contact via structures 86 can be formed on the electrically conductive layers 46 through the contact level dielectric layer 73, and through the retro-stepped dielectric material portion 65. Peripheral gate contact via structures 8G and peripheral active region contact via structures 8A can be formed through the retro-stepped dielectric material portion 65 directly on respective nodes of the peripheral devices.

[0105] The first and second metallic liners (462, 466) can be deposited by a conformal deposition method such as CVD or ALD to provide good coverage, uniform thickness, and uniform barrier property. The tungsten liner 464 can be deposited by a conformal deposition method such as CVD or ALD. The tungsten material in the tungsten liner 464 may be deposited by reduction of WF_6 by a silicon hydride (such as SiH_4 or Si_2H_6) or a boron hydride (such as B_2H_6), and may include residual silicon or residual boron at an atomic concentration in a range from 1.0×10^{20} to 5.0×10^{21} . The continuous metal fill layer 468 may include residual silicon or residual boron at an atomic concentration in a range from 1.0×10^{20} to 5.0×10^{21} and may include a seed layer portion formed employing WF_6 and a hydride of an element such as SiH_4 , Si_2H_6 , Ge_2H_6 , or B_2H_6 which is used to reduce WF_6 , and

a bulk portion formed on the seed layer employing WF_6 and H_2 which is used to reduce WF_6 .

[0106] FIG. 15A illustrates a region of a first alternative embodiment of the exemplary structure, which is derived from the exemplary structure illustrated in FIG. 13 by omitting formation of the backside blocking dielectric layer 44. In this case, the liner stack (462, 464, 466) can physically contact sidewalls of the memory stack structures 55, horizontal surfaces of the insulating layers 32, and sidewalls of the tubular dielectric spacers 116. In this case, the electrically conductive layers 46 are formed directly on horizontal surfaces of the insulating layers 32 and sidewalls of the memory stack structures 55.

[0107] FIG. 15B illustrates a region of a second alternative embodiment of the exemplary structure, which is derived from the exemplary structure illustrated in FIG. 13 by replacing the liner stack (462, 462, 466) consisting of a first metallic nitride liner 462, a tungsten liner 464, and a second metallic nitride liner 466 with a liner stack (462, 464, 466, 463 467), including from one side to another, a first metallic nitride liner 462, a first tungsten liner 464 which can be the same as the tungsten liner 464 in composition and thickness, a second metallic nitride liner 466, a second tungsten liner 463 which can be the same as the tungsten liner 464 in composition and thickness, and a third metallic nitride liner 467 which can be the same as any of the first metallic nitride liner 462 described above or any of the second metallic nitride liner 466 in composition and thickness. In an illustrative example, the liner stack (462, 464, 466, 463 467) in the second alternative embodiment of the exemplary structure can include, from one side to another, a first TiN liner, a first W liner, a second TiN liner, a second W liner, and a third TiN liner that contacts the metal fill portion 468 (which may be a W portion).

[0108] FIG. 15C illustrates a region of a third alternative embodiment of the exemplary structure, which is derived from the second alternative embodiment of the exemplary

structure illustrated in FIG. 15B by omitting formation of the backside blocking dielectric layer 44. In this case, the liner stack (462, 464, 466, 463, 467) can physically contact sidewalls of the memory stack structures 55, horizontal surfaces of the insulating layers 32, and sidewalls of the tubular dielectric spacers 116. In this case, the electrically conductive layers 46 are formed directly on horizontal surfaces of the insulating layers 32 and sidewalls of the memory stack structures 55.

[0109] The exemplary structure of the present disclosure can include a three-dimensional memory device. The three-dimensional memory device includes an alternating stack (32, 46) of insulating layers 32 and electrically conductive layers 46 located over a substrate (9, 10) and memory stack structures 55 extending through the alternating stack (32, 46). Each of the memory stack structures (32, 46) comprises a memory film 55 and a vertical semiconductor channel 60. Each of the electrically conductive layers 46 comprises a liner stack (462, 464, 466) of a first metallic nitride liner 462, a tungsten liner 464 contacting the first metallic nitride liner 462, and a second metallic nitride liner 466 contacting the tungsten liner 464. Each of the electrically conductive layers 46 comprises a metal fill portion 468 contacting a respective second metallic nitride liner 466.

[0110] The three-dimensional memory device can further include a backside trench 79 extending through the alternating stack (32, 46), and an insulating spacer 74 located at a periphery of the backside trench 79. The vertically coincident sidewalls of the first metallic nitride liner 462, the tungsten liner 464, and the second metallic nitride liner 464 can be in physical contact with an outer sidewall of the insulating spacer 74. A source region 61 can be located in an upper portion of the substrate (9, 10) and underlie the backside trench 79. A backside contact via structure 76 can contact the source region 61 and can be laterally surrounded by the insulating spacer 74.

[0111] In one embodiment, the metal fill portion 468 is spaced from the tungsten liner 464 by the second metallic nitride liner 466. In one embodiment, the first metallic nitride liner 462, the tungsten liner 464, and the second metallic nitride liner 466 comprise vertically coincident sidewalls located within a vertical plane, which can include an outer sidewall of the insulating spacer 74. In one embodiment, the metal fill portion 468 includes a sidewall that is vertically coincident with the vertically coincident sidewalls of the first metallic nitride liner 462, the tungsten liner 464, and the second metallic nitride liner 466.

[0112] In one embodiment, the three-dimensional memory device can optionally include a backside blocking dielectric layer 44 contacting horizontal surfaces of the insulating layers 32 and horizontal surfaces and sidewalls of the liner stack (462, 464, 466) and sidewalls of the memory stack structures 55. In one embodiment, a backside blocking dielectric layer is not employed, and the liner stack (462, 464, 466) can contact horizontal surfaces of the insulating layers 32 and sidewalls of the memory stack structures 55.

[0113] In one embodiment, the alternating stack (32, 46) can comprise a terrace region in which each electrically conductive layer 46 other than a topmost electrically conductive layer 46 within the alternating stack (32, 46) laterally extends farther than any overlying electrically conductive layers 46 within the alternating stack (32, 46). The terrace region includes stepped surfaces of the alternating stack (32, 46) that continuously extend from a bottommost layer within the alternating stack (32, 46) to a topmost layer within the alternating stack (32, 46).

[0114] In one embodiment, the three-dimensional memory device comprises a vertical NAND device located over the substrate (9, 10); the electrically conductive layers 46 comprise, or are electrically connected to, a respective word line of the NAND device; the substrate (9, 10) comprises a silicon substrate; the vertical NAND device comprises an array

of monolithic three-dimensional NAND strings over the silicon substrate; at least one memory cell in a first device level of the array of monolithic three-dimensional NAND strings is located over another memory cell in a second device level of the array of monolithic three-dimensional NAND strings; and the silicon substrate contains an integrated circuit comprising a driver circuit for the memory device located thereon. The array of monolithic three-dimensional NAND strings can comprise: a plurality of semiconductor channels (60, 11, and a surface portion of the semiconductor material layer between the source region 61 and the epitaxial channel portions 11) , wherein at least one end portion of each of the plurality of semiconductor channels extends substantially perpendicular to a top surface of the substrate (9, 10); a plurality of charge storage elements, each charge storage element located adjacent to a respective one of the plurality of semiconductor channels; and a plurality of control gate electrodes having a strip shape extending substantially parallel to the top surface of the substrate (9, 10), (for example, along the first horizontal direction), the plurality of control gate electrodes comprise at least a first control gate electrode located in the first device level and a second control gate electrode located in the second device level.

[0115] FIG. 16 is a graph comparing distribution of ^{10}B (e.g., if B_2H_6 is used to reduce tungsten hexafluoride used to deposit tungsten) in an exemplary structure and a reference structure. FIG. 17 is a graph comparing distribution of fluorine atoms in the exemplary structure and the reference structure. The exemplary structure employs a TiN/W/TiN stack (462, 464, 466) as a metallic liner stack (i.e., a diffusion barrier stack) between a tungsten portion and a silicon portion according to an embodiment of the present disclosure. The reference structure employs only a titanium nitride liner between a tungsten portion and a silicon portion. The silicon portion may correspond to the memory stack structure 55.

[0116] For the exemplary structure of FIGS. 16 and 17, the horizontal axis represents a

lateral distance from a reference point within a metal fill portion 468 along a horizontal direction toward a center axis of a memory stack structure. The distance of 11 nm corresponds to an interface between the metal fill portion 468 consisting essentially of tungsten and the second metallic nitride liner 466 consisting essentially of titanium nitride, the distance of 15 nm corresponds to an interface between the second metallic nitride liner 466 and the tungsten liner 464, the distance of 19 nm corresponds to the interface between the tungsten liner 464 and the first metallic nitride liner 462 consisting essentially of titanium nitride, and the distance of 26 nm corresponds to the interface between the first metallic nitride liner 462 and a silicon portion including boron and/or fluorine.

[0117] The reference structure of FIGS. 16 and 17 can be derived from the exemplary structure of FIG. 14 by replacing the liner stack (462, 464, 466) of the exemplary structure with a single layer of TiN having the same thickness as the exemplary structure of FIGS. 16 and 17 (i.e., 15 nm). For the reference structure of FIGS. 16 and 17, the horizontal axis represents a lateral distance from a reference point within a metal fill portion along a horizontal direction toward a center axis of a memory stack structure. The distance of 11 nm corresponds to an interface between the metal fill portion consisting essentially of tungsten and a TiN liner, and the distance of 26 nm corresponds to the interface between the TiN liner and a silicon portion.

[0118] The y-axis in FIGS. 16 and 17 corresponds to the respective boron and fluorine concentration (e.g., such as a concentration determined by secondary ion mass spectroscopy (SIMS)) in units of atoms / cm³ after an anneal step. A first ¹⁰B concentration curve 1610 in FIG. 16 represents concentration of ¹⁰B in the reference structure, and a second ¹⁰B concentration curve 1620 in FIG. 16 represents concentration of ¹⁰B in the exemplary structure. The liner stack (462, 464, 466) of the exemplary structure according to an

embodiment of the present disclosure functions as a superior barrier against boron diffusion than a single TiN layer having the same thickness as provided in the reference structure. If the liner stack (462, 462, 466) is employed within an electrically conductive layer in the exemplary structure of FIGS. 13 – 15, the liner stack (462, 462, 466) can effectively block diffusion of boron atoms between the electrically conductive layers 46 and the memory stack structures 55.

[0119] A first fluorine concentration curve 1710 in FIG. 17 represents concentration of fluorine atoms in the reference structure, and a second fluorine concentration curve 1720 in FIG. 17 represents concentration of fluorine atoms in the exemplary structure. The liner stack (462, 464, 466) of the exemplary structure according to an embodiment of the present disclosure functions as a superior barrier against fluorine diffusion than a single TiN layer having the same thickness as provided in the reference structure. If the liner stack (462, 462, 466) is employed within an electrically conductive layer in the exemplary structure of FIGS. 13 – 15, the liner stack (462, 462, 466) can effectively block diffusion of fluorine atoms between the electrically conductive layers 46 and the memory stack structures 55.

[0120] The various embodiments of the present disclosure provide structures that reduce diffusion of dopant species (such as B and/or F) from the tungsten precursors used to deposit the tungsten fill portion 468 by employing a multi-layer liner stack (462, 464, 466, and optionally 463 and 467). It is believed that the various embodiments of the present disclosure can suppress or retard void formation in the blocking dielectrics (44, 502) and/or in the insulating layers 32 (which can include aluminum oxide and/or silicon oxide material that is prone to void formation by fluorine atoms), and thus, reduce or eliminate leakage current through the electrically conductive layers 46 that are employed as word lines. Thus, the various embodiments of the present disclosure can enhance data retention in a three-

dimensional memory device and/or lead to more stable threshold voltages.

[0121] Although the foregoing refers to particular preferred embodiments, it will be understood that the disclosure is not so limited. It will occur to those of ordinary skill in the art that various modifications may be made to the disclosed embodiments and that such modifications are intended to be within the scope of the disclosure. Where an embodiment employing a particular structure and/or configuration is illustrated in the present disclosure, it is understood that the present disclosure may be practiced with any other compatible structures and/or configurations that are functionally equivalent provided that such substitutions are not explicitly forbidden or otherwise known to be impossible to one of ordinary skill in the art. All of the publications, patent applications and patents cited herein are incorporated herein by reference in their entirety.

WHAT IS CLAIMED IS:

1. A three-dimensional memory device comprising:

an alternating stack of insulating layers and electrically conductive layers located over a substrate; and

memory stack structures extending through the alternating stack, wherein each of the memory stack structures comprises a memory film and a vertical semiconductor channel, wherein each of the electrically conductive layers comprises:

a liner stack of a first metallic nitride liner, a tungsten liner contacting the first metallic nitride liner, and a second metallic nitride liner contacting the tungsten liner; and
a metal fill portion contacting the second metallic nitride liner.

2. The three-dimensional memory device of Claim 1, wherein:

the liner stack comprises a fluorine diffusion barrier;
the metal fill portion comprises a tungsten fill portion;
the first and the second metallic nitride liners comprise titanium nitride liners; and
the metal fill portion is spaced from the tungsten liner by the second metallic nitride liner.

3. The three-dimensional memory device of Claim 1, further comprising:

a backside trench extending through the alternating stack; and
an insulating spacer located at a periphery of the backside trench.

4. The three-dimensional memory device of Claim 3, wherein:

the first metallic nitride liner, the tungsten liner, and the second metallic nitride liner comprise vertically coincident sidewalls located within a vertical plane in the backside trench; and

the vertically coincident sidewalls of the first metallic nitride liner, the tungsten liner, and the second metallic nitride liner are in physical contact with an outer sidewall of the insulating spacer.

5. The three-dimensional memory device of Claim 3, wherein the metal fill portion includes a sidewall that is vertically coincident with the vertically coincident sidewalls of the first metallic nitride liner, the tungsten liner, and the second metallic nitride liner.

6. The three-dimensional memory device of Claim 3, further comprising:

a source region located in an upper portion of the substrate and underlying the backside trench; and

a backside contact via structure contacting the source region and laterally surrounded by the insulating spacer.

7. The three-dimensional memory device of Claim 1, further comprising a backside blocking dielectric layer contacting horizontal surfaces of the insulating layers and horizontal surfaces and sidewalls of the liner stack and sidewalls of the memory stack structures, wherein the liner stack contacts the backside blocking dielectric.

8. The three-dimensional memory device of Claim 1, wherein the liner stack contacts horizontal surfaces of the insulating layers and sidewalls of the memory stack structures.

9. The three-dimensional memory device of Claim 1, wherein:

the second metallic nitride liner comprises an upper horizontal second metallic nitride portion contacting a top surface of a respective metal fill portion, a lower horizontal second metallic nitride portion contacting a bottom surface of the respective metal fill portion, and a vertical second metallic nitride portion contacting a sidewall of the respective metal fill portion;

the tungsten liner comprises an upper horizontal tungsten portion contacting a top surface of a respective upper horizontal second metallic nitride portion, a lower horizontal tungsten portion contacting a bottom surface of a respective lower horizontal second metallic nitride portion, and a vertical tungsten portion contacting a sidewall of a respective vertical second metallic nitride portion; and

the first metallic nitride liner comprises an upper horizontal first metallic nitride portion contacting a top surface of a respective upper horizontal tungsten portion, a lower horizontal first metallic nitride portion contacting a bottom surface of a respective lower horizontal tungsten portion, and a vertical first metallic nitride portion contacting a sidewall of a respective vertical tungsten portion.

10. The three-dimensional memory device of Claim 1, wherein:

the memory film comprises a blocking dielectric layer, a charge storage layer and a tunneling dielectric layer; and

the alternating stack comprises a terrace region in which each electrically conductive layer other than a topmost electrically conductive layer within the alternating stack laterally extends farther than any overlying electrically conductive layers within the alternating stack,

and the terrace region includes stepped surfaces of the alternating stack that continuously extend from a bottommost layer within the alternating stack to a topmost layer within the alternating stack.

11. The three-dimensional memory device of Claim 1, wherein:

the three-dimensional memory device comprises a vertical NAND device located over the substrate;

the electrically conductive layers comprise, or are electrically connected to, a respective word line of the NAND device;

the substrate comprises a silicon substrate;

the vertical NAND device comprises an array of monolithic three-dimensional NAND strings over the silicon substrate;

at least one memory cell in a first device level of the array of monolithic three-dimensional NAND strings is located over another memory cell in a second device level of the array of monolithic three-dimensional NAND strings;

the silicon substrate contains an integrated circuit comprising a driver circuit for the memory device located thereon; and

the array of monolithic three-dimensional NAND strings comprises:

a plurality of semiconductor channels, wherein at least one end portion of each of the plurality of semiconductor channels extends substantially perpendicular to a top surface of the substrate;

a plurality of charge storage elements, each charge storage element located adjacent to a respective one of the plurality of semiconductor channels; and

a plurality of control gate electrodes having a strip shape extending

substantially parallel to the top surface of the substrate, the plurality of control gate electrodes comprise at least a first control gate electrode located in a first device level and a second control gate electrode located in a second device level.

12. A method of forming a three-dimensional memory device, comprising:

forming an alternating stack of insulating layers and spacer material layers over a substrate;

forming memory stack structures through the alternating stack, wherein each of the memory stack structures comprises a memory film and a vertical semiconductor channel; and

replacing the spacer material layers with electrically conductive layers, wherein each of the electrically conductive layers comprises:

a liner stack of a first metallic nitride liner, a tungsten liner contacting the first metallic nitride liner, and a second metallic nitride liner contacting the tungsten liner; and
a metal fill portion contacting the second metallic nitride liner.

13. The method of Claim 12, further comprising:

forming backside recesses by removing the spacer material layers;

forming a continuous layer stack including multiple continuous conductive layers in the backside recesses; and

patterning the continuous layer stack to form the electrically conductive layers.

14. The method of Claim 13, wherein:

the continuous layer stack comprises a first continuous metallic nitride layer, a continuous tungsten layer, a second continuous metallic nitride layer, and a continuous metal

fill layer;

each patterned portion of the first continuous metallic nitride layer is a first metallic nitride liner;

each patterned portion of the continuous tungsten layer is a tungsten liner;

each patterned portion of the second continuous metallic nitride layer is a second metallic nitride liner; and

each patterned portion of the continuous metal fill layer is a metal fill portion.

15. The method of Claim 14, wherein each of the first continuous metallic nitride layer, the continuous tungsten layer, and the second continuous metallic nitride layer is formed by a respective conformal deposition process with a respective uniform thickness throughout.

16. The method of Claim 13, further comprising:

forming a backside trench through the alternating stack;

providing an etchant that removes the sacrificial material layers selective to the insulating layers into the backside trench, wherein the etchant etches the sacrificial material layers to form the backside recesses;

forming an insulating spacer in the backside trench directly on physically exposed sidewalls of the electrically conductive layers;

forming a source region located in an upper portion of the substrate underneath the backside trench; and

forming a backside contact via structure contacting the source region and laterally surrounded by the insulating spacer.

17. The method of Claim 13, further comprising forming a backside blocking dielectric layer directly on horizontal surfaces of the insulating layers and sidewalls of the memory stack structures within the backside recesses, wherein the electrically conductive layers are formed directly on the backside blocking dielectric layer.

18. The method of Claim 12, wherein the electrically conductive layers are formed directly on horizontal surfaces of the insulating layers and sidewalls of the memory stack structures.

19. The method of Claim 12, wherein:

the metal fill portion comprises a tungsten fill portion formed using tungsten hexafluoride;

the first and the second metallic nitride liners comprise titanium nitride liners; and

the liner stack comprises a fluorine diffusion barrier which reduces diffusion of fluorine from the tungsten fill portion into the memory stack structures.

20. The method of Claim 19, wherein:

the metal fill portion comprises a tungsten fill portion formed using tungsten hexafluoride reduced by B_2H_6 ; and

the liner stack comprises a fluorine and boron diffusion barrier which reduces diffusion of fluorine and boron from the tungsten fill portion into the memory stack structures.

21. The method of Claim 12, wherein:

the three-dimensional memory device comprises a vertical NAND device located over

the substrate;

the electrically conductive layers comprise, or are electrically connected to, a respective word line of the NAND device;

the substrate comprises a silicon substrate;

the vertical NAND device comprises an array of monolithic three-dimensional NAND strings over the silicon substrate;

at least one memory cell in a first device level of the array of monolithic three-dimensional NAND strings is located over another memory cell in a second device level of the array of monolithic three-dimensional NAND strings;

the silicon substrate contains an integrated circuit comprising a driver circuit for the memory device located thereon; and

the array of monolithic three-dimensional NAND strings comprises:

a plurality of semiconductor channels, wherein at least one end portion of each of the plurality of semiconductor channels extends substantially perpendicular to a top surface of the substrate;

a plurality of charge storage elements, each charge storage element located adjacent to a respective one of the plurality of semiconductor channels; and

a plurality of control gate electrodes having a strip shape extending substantially parallel to the top surface of the substrate, the plurality of control gate electrodes comprise at least a first control gate electrode located in a first device level and a second control gate electrode located in a second device level.
