SUBSTITUTED AMINE DERIVATIVES AND METHODS OF USE

FIELD OF THE INVENTION

This invention is in the field of pharmaceutical agents and specifically relates to compounds, compositions, uses and methods for treating cancer and angiogenesis-related disorders.

BACKGROUND OF THE INVENTION

Protein kinases represent a large family of proteins which play a central role in the regulation of a wide variety of cellular processes, maintaining control over cellular function. A partial list of such kinases includes abl, Akt, bcr-abl, Blk, Brk, Btk, c-kit, c-met, c-src, CDK1, CDK2, CDK3, CDK4, CDK5, CDK6, CDK7, CDK8, CDK9, CDK10, cRaf1, CSF1R, CSK, EGFR, ErbB2, ErbB3, ErbB4, Erk, Fak, fes, FGFR1, FGFR2, FGFR3, FGFR4, FGFR5, Fgr, flt-1, Fps, Frk, Fyn, Hck, IGF-1R, INS-R, Jak, KDR, Lck, Lyn, MEK, p38, PDGFR, PIK, PKC, PYK2, ros, tie, tie2, TRK, Yes, and Zap70. Inhibition of such kinases has become an important therapeutic target.

Certain diseases are known to be associated with deregulated angiogenesis, for example ocular neovascularisation, such as retinopathies (including diabetic retinopathy), age-related macular degeneration, psoriasis, hemangioblastoma, hemangioma, arteriosclerosis, inflammatory disease, such as a rheumatoid or rheumatic inflammatory disease, especially arthritis (including rheumatoid arthritis), or other chronic inflammatory disorders, such as chronic asthma, arterial or post-transplantational atherosclerosis, endometriosis, and neoplastic diseases, for example so-called solid tumors and liquid tumors (such as leukemias).
At the center of the network regulating the growth and differentiation of the vascular system and its components, both during embryonic development and normal growth, and in a wide number of pathological anomalies and diseases, lies the angiogenic factor known as Vascular Endothelial Growth Factor" (VEGF; originally termed 'Vascular Permeability Factor', VPF), along with its cellular receptors (see G. Breier et al., Trends in Cell Biology, 6, 454-6 (1996)).

VEGF is a dimeric, disulfide-linked 46-kDa glycoprotein related to "Platelet-Derived Growth Factor" (PDGF); it is produced by normal cell lines and tumor cell lines; is an endothelial cell-specific mitogen; shows angiogenic activity in in vivo test systems (e.g. rabbit cornea); is chemotactic for endothelial cells and monocytes; and induces plasminogen activators in endothelial cells, which are involved in the proteolytic degradation of extracellular matrix during the formation of capillaries. A number of isoforms of VEGF are known, which show comparable biological activity, but differ in the type of cells that secrete them and in their heparin-binding capacity. In addition, there are other members of the VEGF family, such as "Placenta Growth Factor" (PlGF) and VEGF-C.

VEGF receptors (VEGFR) are transmembranous receptor tyrosine kinases. They are characterized by an extracellular domain with seven immunoglobulin-like domains and an intracellular tyrosine kinase domain. Various types of VEGF receptor are known, e.g. VEGFR-1 (also known as flt-1), VEGFR-2 (also known as KDR), and VEGFR-3.

A large number of human tumors, especially gliomas and carcinomas, express high levels of VEGF and its receptors. This has led to the hypothesis that the VEGF released by tumor cells stimulates the growth of blood capillaries and the proliferation of tumor endothelium in a paracrine manner and through the improved blood supply, accelerate tumor
growth. Increased VEGF expression could explain the occurrence of cerebral edema in patients with glioma. Direct evidence of the role of VEGF as a tumor angiogenesis factor in vivo is shown in studies in which VEGF expression or VEGF activity was inhibited. This was achieved with anti-VEGF antibodies, with dominant-negative VEGFR-2 mutants which inhibited signal transduction, and with antisense-VEGF RNA techniques. All approaches led to a reduction in the growth of glioma cell lines or other tumor cell lines in vivo as a result of inhibited tumor angiogenesis.

Angiogenesis is regarded as an absolute prerequisite for tumors which grow beyond a diameter of about 1-2 mm; up to this limit, oxygen and nutrients may be supplied to the tumor cells by diffusion. Every tumor, regardless of its origin and its cause, is thus dependent on angiogenesis for its growth after it has reached a certain size.

Three principal mechanisms play an important part in the activity of angiogenesis inhibitors against tumors: 1) Inhibition of the growth of vessels, especially capillaries, into avascular resting tumors, with the result that there is no net tumor growth owing to the balance that is achieved between cell death and proliferation; 2) Prevention of the migration of tumor cells owing to the absence of blood flow to and from tumors; and 3) Inhibition of endothelial cell proliferation, thus avoiding the paracrine growth-stimulating effect exerted on the surrounding tissue by the endothelial cells which normally line the vessels. See R. Connell and J. Beebe, Exp. Opin. Ther. Patents, 11, 77-114 (2001).

VEGF’s are unique in that they are the only angiogenic growth factors known to contribute to vascular hyperpermeability and the formation of edema. Indeed, vascular hyperpermeability and edema that is associated with
the expression or administration of many other growth factors appears to be mediated via VEGF production.

Inflammatory cytokines stimulate VEGF production. Hypoxia results in a marked upregulation of VEGF in numerous tissues, hence situations involving infarct, occlusion, ischemia, anemia, or circulatory impairment typically invoke VEGF/VPF-mediated responses. Vascular hyperpermeability, associated edema, altered transendothelial exchange and macromolecular extravasation, which is often accompanied by diapedesis, can result in excessive matrix deposition, aberrant stromal proliferation, fibrosis, etc. Hence, VEGF-mediated hyperpermeability can significantly contribute to disorders with these etiologic features. As such, regulators of angiogenesis have become an important therapeutic target.

WO00/02851, published 20 Jan 2000 describes arylsulfonylaminoaryl amides as guanylate cyclase activators. W098/45268 describes nicotinamide derivatives as PDE4 inhibitors. W098/24771 describes benzamides as vasopressin antagonists.

US Patent No. 5,532,358, issued July 2, 1996, describes the preparation of 2-(cyclopropylamino)-N-(2-methoxy-4-methyl-3-pyridinyl)-3-pyridinecarboxamide as an intermediate for HIV inhibitors. Triazine-substituted amines are described for their aggregating ability (J. Amer.

**Definitions**

The term "treatment" includes therapeutic treatment as well as prophylactic treatment (either preventing the onset of disorders altogether or delaying the onset of a preclinically evident stage of disorders in individuals).

A "pharmaceutically-acceptable derivative" denotes any salt, ester of a compound of this invention, or any other compound which upon administration to a patient is capable of providing (directly or indirectly) a compound of this invention, or a metabolite or residue thereof, characterized by the ability to inhibit angiogenesis.

The phrase "therapeutically-effective" is intended to qualify the amount of each agent, which will achieve the goal of improvement in disorder severity and the frequency of incidence over treatment of each agent by itself, while avoiding adverse side effects typically associated with alternative therapies. For example, effective neoplastic therapeutic agents prolong the survivability of the patient, inhibit the rapidly-proliferating cell growth associated with the neoplasm, or effect a regression of the neoplasm.

COMBINATIONS

While the compounds of the invention can be administered as the sole active pharmaceutical agent, they can also be used in combination with one or more compounds of the invention or other agents. When administered as a combination, the therapeutic agents can be formulated as separate compositions that are administered at the same time or sequentially at different times, or the therapeutic agents can be given as a single composition.

The phrase "co-therapy" (or "combination-therapy"), in defining use of a compound of the present invention and another pharmaceutical agent, is intended to embrace administration of each agent in a sequential manner in a regimen that will provide beneficial effects of the drug combination, and is intended as well to embrace co-administration of these agents in a substantially simultaneous manner, such as in a single capsule having a fixed ratio of these active agents or in multiple, separate capsules for each agent.

Specifically, the administration of compounds of the present invention may be in conjunction with additional therapies known to those skilled in the art in the prevention or treatment of neoplasia, such as with radiation therapy or with cytostatic or cytotoxic agents.

If formulated as a fixed dose, such combination products employ the compounds of this invention within the accepted dosage ranges. Compounds of Formula I may also be administered sequentially with known anticancer or cytotoxic agents when a combination formulation is inappropriate. The invention is not limited in the sequence of administration; compounds of the invention may be administered either prior to, simultaneous with or after administration of the known anticancer or cytotoxic agent.
Currently, standard treatment of primary tumors consists of surgical excision followed by either radiation or IV administered chemotherapy. The typical chemotherapy regime consists of either DNA alkylating agents, DNA intercalating agents, CDK inhibitors, or microtubule poisons. The chemotherapy doses used are just below the maximal tolerated dose and therefore dose limiting toxicities typically include, nausea, vomiting, diarrhea, hair loss, neutropenia and the like.

There are large numbers of antineoplastic agents available in commercial use, in clinical evaluation and in pre-clinical development, which would be selected for treatment of neoplasia by combination drug chemotherapy. Such antineoplastic agents fall into several major categories, namely, antibiotic-type agents, alkylating agents, antimetabolite agents, hormonal agents, immunological agents, interferon-type agents and a category of miscellaneous agents.

Alternatively, the present compounds may also be used in co-therapies with other anti-neoplastic agents, such as other kinase inhibitors including p38 inhibitors and CDK
inhibitors, TNF inhibitors, metalloproteinase inhibitors (MMP), COX-2 inhibitors including celecoxib, rofecoxib, parecoxib, valdecoxib, and etoricoxib, NSAID's, SOD mimics or \( \alpha_4 \beta_1 \) inhibitors.

The present invention comprises processes for the preparation of a compound of Formula I-X.

Also included in the family of compounds of Formula I-X are the pharmaceutically-acceptable salts thereof. The term "pharmaceutically-acceptable salts" embraces salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. The nature of the salt is not critical, provided that it is pharmaceutically-acceptable. Suitable pharmaceutically-acceptable acid addition salts of compounds of Formula I-X may be prepared from an inorganic acid or from an organic acid. Examples of such inorganic acids are hydrochloric, hydrobromic, hydroiodic, nitric, carbonic, sulfuric and phosphoric acid. Appropriate organic acids may be selected from aliphatic, cycloaliphatic, aromatic, arylaliphatic, heterocyclic, carboxylic and sulfonic classes of organic acids, example of which are formic, acetic, adipic, butyric, propionic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric, ascorbic, glucuronic, maleic, fumaric, pyruvic, aspartic, glutamic, benzoic, anthranilic, mesylic, 4-hydroxybenzoic, phenylacetic, mandelic, embonic (pamoic), methanesulfonic, ethanesulfonic, ethanedisulfonic, benzenesulfonic, pantothentic, 2-hydroxyethanesulfonic, toluenesulfonic, sulfanilic, cyclohexylaminoisulfonic, camphoric, camphorsulfonic, digluconic, cyclopentane-propionic, dodecylsulfonic, glucoheptanoic, glycerophosphoric, heptanoic, hexanoic, 2-hydroxy-ethanesulfonic, nicotinic, 2-naphthalenesulfonic, oxalic, palmoic, pectinic, persulfuric, 2-phenylpropionic, picric, pivalic propionic, succinic, tartaric, thiocyanic, mesylic,
undecanoic, stearic, algenic, β-hydroxybutyric, salicylic, galactaric and galacturonic acid. Suitable pharmaceutically-acceptable base addition salts of compounds of Formula I-X include metallic salts, such as salts made from aluminum, calcium, lithium, magnesium, potassium, sodium and zinc, or salts made from organic bases including primary, secondary and tertiary amines, substituted amines including cyclic amines, such as caffeine, arginine, diethylamine, N-ethyl piperidine, aistidine, glucamine, isopropylamine, lysine, morpholine, N-ethyl morpholine, piperazine, piperidine, triethylamine, trimethylamine. All of these salts may be prepared by conventional means from the corresponding compound of the invention by reacting, for example, the appropriate acid or base with the compound of Formula I-X.

Also, the basic nitrogen-containing groups can be quaternized with such agents as lower alkyl halides, such as methyl, ethyl, propyl, and butyl chloride, bromides and iodides; dialkyl sulfates like dimethyl, diethyl, dibutyl, and diamyl sulfates, long chain halides such as decyl, lauryl, myristyl and stearyl chlorides, bromides and iodides, aralkyl halides like benzyl and phenethyl bromides, and others. Water or oil-soluble or dispersible products are thereby obtained.

Examples of acids that may be employed to form pharmaceutically acceptable acid addition salts include such inorganic acids as hydrochloric acid, sulphuric acid and phosphoric acid and such organic acids as oxalic acid, maleic acid, succinic acid and citric acid. Other examples include salts with alkali metals or alkaline earth metals, such as sodium, potassium, calcium or magnesium or with organic bases. Preferred salts include hydrochloride, phosphate and edisylate.

Additional examples of such salts can be found in Berge et al., J. Pharm. Sci., 66, 1 (1977).
GENERAL SYNTHETIC PROCEDURES

The compounds of the invention can be synthesized according to the following procedures of Schemes 1-31, wherein the substituents are as defined for Formulas I-X, above, except where further noted.

Scheme 1

10 Substituted carboxamides 3 can be prepared from the corresponding halo analogs 1 by the process outlined in Scheme 1. Substituted amino acids 2 are prepared from the corresponding chloro compounds 1 such as by reacting with an amine at a suitable temperature, such as about 80°C. The acid 2 is coupled with an amine, preferably in the presence of a coupling agent such as EDC, to form the corresponding amide 3.

The amination process can be carried out as an Ullmann type reaction using a copper catalyst, such as copper[0] or a copper[I] compound such as copper[I]oxide, copper[I]bromide or copper[I]iodide in the presence of a suitable base (such as a metal carbonate, for example K₂CO₃) to neutralize the acid generated in the reaction.
This reaction is reviewed in Houben-Weyl "Methoden der Organischen Chemie", Band 11/1, page 32-33, 1958, in Organic Reactions, 14, page 19-24, 1965 and by J. Lindley (1984) in Tetrahedron, 40, page 1433-1456. The amount of catalyst is typically in the range of 1 to 20 mole percent. The reaction is carried out in an inert, aprotic solvent such as an ether (for example dimethoxyethane or dioxane) or an amide (for example dimethylformamide or N-methylpyrrolidone), under an inert atmosphere in the temperature range of 60-180°C.

An alternative amination process involves using a Group VIII element, where the metal core of the catalyst should be a zero-valent transition metal, such as palladium or nickel, which has the ability to undergo oxidative addition to the aryl-halogen bond. The zero valent state of the metal may be generated in situ from the M[II] state. The catalyst complexes may include chelating ligands, such as alkyl, aryl or heteroaryl derivatives of phosphines or biphosphines, imines or arsines. Preferred catalysts contain palladium or nickel. Examples of such catalysts include palladium[II]chloride, palladium[II]acetate, tetrakis(triphenyl-phosphine)palladium[0] and nickel[II]acetylacetonate. The metal catalyst is typically in the range of 0.1 to 10 mole percent. The chelating ligands may be either monodentate, as in the case for example of trialkylphosphines, such as tributylphosphine, triarylphosphines, such as tri-(ortho-tolyl)phosphine, and triheteroaryl phosphines, such as tri-2-furylphosphine; or they may be bidentate such as in the case of 2,2'-bis(diphenylphosphino)- 1,1'binaphthyl, 1,2-bis(diphenylphosphino)ethane, 1,1'-bis(diphenylphosphino)ferrocene and 1-(N,N-dimethyl-amino)-1'-(dicyclohexylphosphino)biphenyl. The supporting ligand may be complexed to the metal center in the form of a metal
complex prior to being added to the reaction mixture or may be added to the reaction mixture as a separate compound. The supporting ligand is typically present in the range 0.01 to 20 mole percent. It is often necessary to add a suitable base to the reaction mixture, such as a trialkylamine (for example, DIIBA or 1,5-diazabicyclo[5,4,0]undec-5-ene), a Group I alkali metal alkoxide (for example potassium tert-butoxide) or carbonate (for example cesium carbonate) or potassium phosphate. The reaction is typically carried out in an inert solvent such as an ether (for example dimethoxyethane or dioxane) or an amide (for example, DMF or N-methylpyrrolidone), under an inert atmosphere in the temperature range of 60-180°C.

The amination is preferably carried out in an inert, aprotic, preferably anhydrous, solvent or solvent mixture, for example in a carboxylic acid amide, for example DMF or dimethylacetamide, a cyclic ether, for example THF or dioxane, or a nitrile, for example CH₃CN, or in a mixture thereof, at an appropriate temperature, for example in a temperature range of from about 40°C to about 180°C, and if necessary under an inert gas atmosphere, for example a nitrogen or argon atmosphere.
Substituted carboxamides 3 can be prepared from the corresponding halo analogs 1A by the process outlined in Scheme 2. The chloro acid 1 (LG is OH) is coupled with an amine, preferably in the presence of a coupling agent such as EDC, to form the corresponding chloro amide 4. Substituted amino-amides 3 are prepared from the corresponding chloro compounds 4 such as by reacting with an amine at a suitable temperature, such as about 80°C. The amination reaction can be run in the presence of an appropriate catalyst such as a palladium catalyst, in the presence of an aprotic base such as sodium t-butoxide or cesium carbonate, or a nickel catalyst, or a copper catalyst.

Alternatively, carboxamides 3 can be prepared from 2-chloro-heterocyclyl acid chloride 1A (LG is Cl) by coupling first with R₁-NH₂ such as in the presence of base, e.g., NaHCO₃, in a suitable solvent, such as CH₂Cl₂, to form the
amide 1B, then coupling with a primary or secondary amine to yield the substituted carboxamide 3.

Additionally, where A is a pi-electron rich heterocycle, the addition of KF, such as 40% KF on alumina in IpOH, at a temperature over about 100°C, preferably about 160°C, can be used in the formation of 3 from 1B.

Scheme 3

Substituted carboxamides 3 can be prepared from the corresponding bromo/chloro analogs 5 by the process outlined in Scheme 3. The bromo/chloro acid 5 is coupled with an amine, preferably in the presence of a coupling agent such as EDC, to form the corresponding bromo substituted amide 6. Suzuki coupling with the bromo amide 6 and suitable boronic acids provides the substituted amide 4. Substituted aminoamides 3 are prepared from the corresponding chloro compounds 4 as described in Scheme 2.
Substituted pyridines can be prepared by the process outlined in Scheme 4. A solution of sodium hypobromite is freshly prepared and added to a 2-hydroxynicotinic acid 7 and heated, preferably at a temperature at about 50°C. Additional sodium hypobromide may be needed to form the bromo compound 8. The 5-bromo-2-hydroxynicotinic acid 8 is reacted with thionyl chloride, preferably at a temperature >RT, more preferably at about 80°C to form the 2-chloronicotinic acid analog 9. The acid is coupled with an amine,
preferably in the presence of EDC, HOBT, and DIEA to form the corresponding substituted amide 10. Suzuki coupling with the bromo amide and suitable boronic acids, provides the substituted nicotinamide 11. 2-Amino-nicotinamides 12 are prepared from the corresponding chloro compounds 11 such as by reacting with substituted amines at a suitable temperature, such as about 80°C.

Scheme 5

Alkylated indazoles can be prepared by the process outlined in Scheme 5. To a solution of 6-nitroindazole 13 in a solvent such as THF is added strong base, such as NaH at a temperature below RT, preferably at about 0°C. Alkylhalides, such as where R* is methyl, are added and reacted at a temperature about RT to give 1-alkyl-6-nitro-1H-indazole 14. The nitro indazole 14 is hydrogenated, such as with an H2 atmosphere in the presence of a catalyst, such as Pd/C to give the 1-substituted-6-amino-1H-indazole 15.

Scheme 6
Brominated indazoles can be prepared by the process outlined in Scheme 6. NBS is slowly added to an acidic solution, such as a mixture of TFA: H₂SO₄ (5:1) and tert-butyl-4-nitrobenzene 16 at a temperature of about RT to yield the brominated compound 17.

**Scheme 7**

Substituted anilines can be prepared by the process outlined in Scheme 7. A mixture of 1- (substituted)-2-bromo-4-nitrobenzene 18 (where R² is a substituent selected from those available for substituted R³) and N-methylpiperazine is heated, such as with or without solvent, preferably without solvent, at a temperature above RT, preferably at a temperature above about 100°C, and more preferably at a temperature at about 130°C to give the 1-[5-(substituted)-2-nitrophenyl]-4-methylpiperazine 19. The nitro compound 19 is hydrogenated, such as with an H₂ atmosphere in the presence of a catalyst, such as Pd/C to furnish 4- (substituted)-2-(4-methylpiperazinyl)phenylamine 20.
Tricyclic heterocycles can be prepared by the process outlined in Scheme 8. 7-Nitro-2,3,4-trihydroisoquinolin-1-one 21 is heated in POCl₃ at a temperature above RT, preferably at a temperature sufficient for reflux, to form the 1-chloro-7-nitro-3,4-dihydroisoquinoline 22. The 1-chloro-7-nitro-3,4-dihydroisoquinoline 22 is dissolved in a solvent, such as THF, and H₂NNH₂ is added. The reaction is heated with HC(ΟEt)₃ at a temperature above RT, preferably at a temperature above about 75°C, and more preferably at a temperature at about 115°C to give the nitro-substituted tricyclic. Hydrogenation, such as with an H₂ atmosphere in the presence of a catalyst, such as Pd/C, gives 2-amino-5,6,7-trihydro-1,2,4-triazolo[3,4-a]isoquinoline 23.
Indazoly1 ethers can be prepared by the process outlined in Scheme 9. 6-Nitro-1H-2-hydroindazol-3-one 24 is protected such as with Boc₂O and DMAP in CH₂Cl₂ at a temperature of about RT, to give the protected 6-nitro-2-hydroindazol-3-one. The protected 6-nitro-2-hydroindazol-3-one is reacted with an alcohol (where R⁵ is an appropriate substituent selected from the possible substituents on R¹) and Ph₃P in a solvent, such as THF, and DEAD, at a temperature of about RT, to give the protected 6-nitro(indazol-3-yl) ether. The nitro intermediate is hydrogenated, such as with an H₂ atmosphere in the presence of a catalyst, such as Pd/C, to give the protected 6-amino(indazol-3-yl) ether 25. The amine 25 is coupled with 2-chloronicotinic acid in a solvent, such as an alcohol, preferably pentanol, at a temperature above RT, preferably
at a temperature above about 75°C, and more preferably at a
temperature at about 130°C to give the coupled and
deprotected compound 26.

Indoliny1 substituted carboxamides can be prepared
from the corresponding nitro indoline 27 by the process
outlined in Scheme 10. For example, 3,3-dimethyl-6-
10 nitroindoline 27 is alkylated, such as with N-protected-4-
formylpiperidine in the presence of NaH(OAc)₃ and acid,
such as glacial AcOH, and solvent, such as dichloromethane,
at a temperature of about RT, to afford the alkylated indane
28. Hydrogenation of the alkylated indane 28, such as with an \( \text{H}_2 \) atmosphere in the presence of a catalyst, such as Pd/C, in the presence of a solvent, such as an alcohol, preferably MeOH, to give the amino intermediate 29.

Alternatively, other hydrogenation methods can be used, such as Fe powder with \( \text{NH}_4\text{Cl} \). Coupling of the amine 29, such as with 2-chloronicotinic acid and DIEA, HOBT and EDC, in a solvent such as \( \text{CH}_2\text{Cl}_2 \) at a temperature of about RT provides the protected carboxamide 30, which upon deprotection and alkylation yields other compounds of the invention, 31 and 32, respectively. Alternatively, amine 29 is reacted with 2-fluoronicotinoyl chloride to form a 2-fluoronicotinamide, which can be alkylated, such as in Scheme 10.

The substituted aniline 35 is formed from the 1,3,2-dioxaborolane 34 such as with treatment with an amine in the presence of 1,1'-bis(diphenylphosphino)ferrocene-palladium dichloride and base, such as K\(_2\)CO\(_3\), in a solvent such as DMF at a temperature above RT, preferably at a temperature above about 50\(^\circ\)C, and more preferably at a temperature at about 80\(^\circ\)C.

Alkylation of the phenyl piperidine 37, such as with formaldehyde and NaCNBH₃ in a solvent such as CH₃CN, with sufficient acid to maintain the reaction pH near 7, to provide the alkylated piperidine 38. Nitration of the phenylpiperidine 38, such as with H₂SO₄ and fuming HNO₃ at a temperature below RT, and preferably at about 0°C, gives the nitro intermediate 39. Hydrogenation of the nitro intermediate 39, such as with an H₂ atmosphere in the presence of a catalyst, such as Pd/C, in the presence of a solvent, such as an alcohol, preferably MeOH, to give the amino intermediate 40.

Nitrobenzenes 43 are brominated, such as with bromine in the presence of acid, H₂SO₄ for example, or with NBS to yield the 3-bromo derivative 44. Suzuki coupling of the bromoderivative 44 and a substituted pyridylboronic acid, such as
at a temperature above RT, preferably above about 50°C, and
more preferably at about 80°C, yields the pyridyl derivative
45. Alkylation of the nitrophenyl-pyridine 45, such as by
treatment with iodomethane, preferably above about 50°C, and
more preferably at about 80°C, yields the pyridinium
compound 46, which upon reduction, such as by NaBH₄, yields
the tetrahydropyridine 47.

Scheme 15

A series of substituted anilines are prepared such as

Coupling of nitrobenzenesulfonyl chlorides 52 with reactive heterocyclic compounds, such as substituted piperazines, piperidines, and the like, in a protic solvent such as EtOH, such as at a temperature about RT, yields the nitrobenzenesulfonamides 52. Reduction of the nitro benzenesulfonamide, such as with iron powder, preferably above about 50°C, and more preferably at about 80°C, yields the aniline 53.

Scheme 16

Freskos, Synthetic Communications, 18(9), 965-972 (1988)]. Alternatively, 1-Nitro-4-(perfluoroalkyl)benzene can be synthesized from the nitro compound, where X^a is a leaving group, such as bromo
or iodo, by the method described by W. A. Gregory, et al. [J. Med. Chem., 1990, 33, 2569-2578].

Reduction of the nitrobenzenes 55, such as with iron powder, at a temperature above about 50°C, and preferably at about 80°C, yields the aniline 56. Hydrogenation, such as with H₂ atmosphere in the presence of a catalyst, such as 10% Pd/C, is also possible.

Scheme 17

The N-(2-methylprop-2-enyl)acetamide 74 is prepared from the acetamide 73, such as by the treatment of base, such as NaH in a suitable solvent such as NMP or anhydrous DMF and a 3-halo-2-methylpropene such as 3-bromo-2-methylpropene or 3-chloro-2-methylpropene, at a temperature between about 0°C and RT, and preferably at about RT; or with Cs₂CO₃ at a temperature above RT, preferably above about 50°C and more preferably above about 60°C. Cyclization of the N-(2-methylprop-2-enyl)acetamide 74, such as by the Heck-type reaction (treatment with Pd(OAc)₂ in the presence of base, for example tetraethyl-ammonium chloride, sodium formate, and NaOAc) at a temperature above about 50°C, and preferably at about 80°C, yields the protected (3,3-dimethyl-6-nitro-2,3-dihydro-indol-1-yl)ethanone 75. Alternatively, the protected dihydro-6-nitro indoline 75 can be reduced, such as with Fe, or with 10% Pd/C in the presence of an excess of NH₄Cl or H₂ in the presence of a catalyst to form the protected dihydro-6-amino indoline 75a.
Substituted anilines are prepared such as by the procedures described in Scheme 20. Nitrophenyl esters 78 are formed from the acid 77, such as by treatment with MeOH and acid. Subsequent treatment with methoxymethyltriphenylphosphonium chloride and KHMDS yields 81. Coupling of the aldehyde 81 and morpholine, such as with NaBH(OAc)$_3$, yields the tertiary amine 82. Reduction of the nitro compound, such as with acid, for example AcOH, and zinc yields the aniline 83.
Substituted aniline compounds are prepared such as by the procedure described in Scheme 21 (where R² is a substituent selected those available for substituted R¹, preferably haloalkyl and alkyl). Alkynyl-aniline 90, prepared similar to that described in Scheme 22, is hydrogenated such as with H₂ in the presence of a catalyst, such as Pd(OH)₂, to yield the substituted alkyl 91.

Substituted bromophenyl compounds are prepared such as by the procedure described in Scheme 22. Bromine is added to a optionally substituted nitrobenzene 92, silver(II)sulfate and acid, such as H₂SO₄, to provide the bromo derivative 93.
Substituted anilines are prepared such as by the procedure described in Scheme 23 (where \( R^t \) and \( R^v \) are alkyl, or together with the nitrogen atom form a 4-6 membered heterocyclic ring). Acryloyl chloride 94 is reacted with an amine, preferably a secondary amine, such as at a temperature between about 0°C and about RT, to form the amide 95. A bromo-nitrobenzene 93 is reacted with the amide 95, such as in the presence of base, for example TEA, together with Pd(OAc)\(_2\) and Pd(PPh\(_3\))\(_4\), at a temperature above about 50°C, and preferably at about 120°C, such as in a sealed container, to form the substituted alkene 96. Hydrogenation of the alkene 96, such as with \( \text{H}_2 \)-in the presence of a catalyst, for example Pd/C catalyst yields the substituted aniline 97. Reduction of the amide 97, such as with LiAlH\(_4\), at a temperature above about 50°C, and preferably at about 80°C yields the aniline 98.
Substituted indoles are prepared such as by the procedure described in Scheme 24. A nitroindole 99 is coupled with a halo compound, in the presence of base, for example K₂CO₃. **Scheme 27**

Functionalized pyridines are prepared such as by the procedure described in Scheme 27. 2-Fluoropyridine 108 is treated with base, such as LDA, at a temperature below about 0°C, and preferably at about -78°C, and quenched with a stream of dry CO₂ to form the nicotinic acid 109. Alternatively, solid CO₂ (dry ice) can be used, preferably dried with N₂ prior to use. The acid 109 is converted to the acid halide 110, such as by treatment with thionyl chloride.
and heating at a temperature above about 50°C, and preferably at about reflux.

Reaction with an amine produces amide 113. Alternatively, the amine can be coupled with the acid chloride 111, such as with polymer-supported DIPEA. Excess acid chloride is removed by treating the reaction mixture with polymer-supported trisamine resin, to form amide 113.

**Scheme 29**

Scheme 31

2,3,4,4a,9,9a-hexahydro-1H-3-aza-fluoren-6-ylamine may be prepared by the method found in Scheme 31. Nitrobenzylpyridines 119 are alkylated, such as with MeI, in the presence of TBAI and base to form the pyridinium compound 120. The pyridinium compounds 120 are halogenated, such as brominated with NBS, to form the brominated pyridinium compounds 121 which are reduced such as with NaBH₄, dehalogenated and reduced to form the hexahydrofluorenes 124.

The starting compounds defined in Schemes 1-31 may also be present with functional groups in protected form if necessary and/or in the form of salts, provided a salt-forming group is present and the reaction in salt form is possible. If so desired, one compound of formula I-X can be converted into another compound of formula I-X or a N-oxide.
thereof; a compound of formula I-X can be converted into a salt; a salt of a compound of formula I-X can be converted into the free compound or another salt; and/or a mixture of isomeric compounds of formula I-X can be separated into the individual isomers.

N-Oxides can be obtained in a known matter by reacting a compound of formula I-X with hydrogen peroxide or a peracid, e.g. 3-chloroperoxy-benzoic acid, in an inert solvent, e.g. dichloromethane, at a temperature between about -10-35°C, such as about 0°C - RT.

If one or more other functional groups, for example carboxy, hydroxy, amino, or mercapto, are or need to be protected in a compound of formula I-X or in the preparation of compounds of formula I-X, because they should not take part in the reaction, these are such groups as are usually used in the synthesis of peptide compounds, and also of cephalosporins and penicillins, as well as nucleic acid derivatives and sugars.

The protecting groups may already be present in precursors and should protect the functional groups concerned against unwanted secondary reactions, such as acylations, etherifications, esterifications, oxidations, solvolysis, and similar reactions. It is a characteristic of protecting groups that they lend themselves readily, i.e. without undesired secondary reactions, to removal, typically by solvolysis, reduction, photolysis or also by enzyme activity, for example under conditions analogous to physiological conditions, and that they are not present in the end-products. The specialist knows, or can easily establish, which protecting groups are suitable with the reactions mentioned above and hereinafter.

The protection of such functional groups by such protecting groups, the protecting groups themselves, and their removal reactions are described for example in

In the additional process steps, carried out as desired, functional groups of the starting compounds which should not take part in the reaction may be present in unprotected form or may be protected for example by one or more of the protecting groups mentioned above under "protecting groups". The protecting groups are then wholly or partly removed according to one of the methods described there.

Salts of a compound of formula I-X with a salt-forming group may be prepared in a manner known per se. Acid addition salts of compounds of formula I-X may thus be obtained by treatment with an acid or with a suitable anion exchange reagent. A salt with two acid molecules (for example a dihalogenide of a compound of formula I) may also be converted into a salt with one acid molecule per compound (for example a monohalogenide); this may be done by heating to a melt, or for example by heating as a solid under a high vacuum at elevated temperature, for example from 130 to
170°C, one molecule of the acid being expelled per molecule of a compound of formula I-X.

Salts can usually be converted to free compounds, e.g. by treating with suitable basic agents, for example with alkali metal carbonates, alkali metal hydrogen carbonates, or alkali metal hydroxides, typically potassium carbonate or sodium hydroxide.

A compound of formula I-X, wherein Z is oxygen, can be converted into the respective compound wherein Z is sulfur, for example, by using an appropriate sulfur compound, e.g. using reaction with Lawesson's reagent (2,4-bis-(4-methoxyphenyl)2,4-dithioxo-1,2,3,4-dithiaphosphetan) in a halogenated hydrocarbon, such as CH₂Cl₂, or an aprotic solvent, such as toluene or xylene, at temperatures from about 30°C to reflux.

All process steps described here can be carried out under known reaction conditions, preferably under those specifically mentioned, in the absence of or usually in the presence of solvents or diluents, preferably such as are inert to the reagents used and able to dissolve these, in the absence or presence of catalysts, condensing agents or neutralizing agents, for example ion exchangers, typically cation exchangers, for example in the H⁺ form, depending on the type of reaction and/or reactants at reduced, normal, or elevated temperature, for example in the range from about -100°C to about 190°C, preferably from about -80°C to about 150°C, for example at about -80 to about 60°C, at room temperature, at about -20 to about 40°C or at the boiling point of the solvent used, under atmospheric pressure or in a closed vessel, where appropriate under pressure, and/or in an inert atmosphere, for example under argon or nitrogen.

Salts may be present in all starting compounds and transients, if these contain salt-forming groups. Salts may
also be present during the reaction of such compounds, provided the reaction is not thereby disturbed.

In certain cases, typically in hydrogenation processes, it is possible to achieve stereoselective reactions, allowing for example easier recovery of individual isomers. The solvents from which those can be selected which are suitable for the reaction in question include for example water, esters, typically lower alkyl-lower alkanoates, e.g., ethyl acetate, ethers, typically aliphatic ethers, e.g., diethylether, or cyclic ethers, e.g., THF, liquid aromatic hydrocarbons, typically benzene or toluene, alcohols, typically MeOH, EtOH or 1-propanol, IPOH, nitriles, typically CH$_3$CN, halogenated hydrocarbons, typically CH$_2$Cl$_2$, acid amides, typically DMF, bases, typically heterocyclic nitrogen bases, e.g. pyridine, carboxylic acids, typically lower alkanecarboxylic acids, e.g., AcOH, carboxylic acid anhydrides, typically lower alkane acid anhydrides, e.g., acetic anhydride, cyclic, linear, or branched hydrocarbons, typically cyclohexane, hexane, or isopentane, or mixtures of these solvents, e.g., aqueous solutions, unless otherwise stated in the description of the process. Such solvent mixtures may also be used in processing, for example in chromatography.

The invention relates also to those forms of the process in which one starts from a compound obtainable at any stage as a transient and carries out the missing steps, or breaks off the process at any stage, or forms a starting material under the reaction conditions, or uses said starting material in the form of a reactive derivative or salt, or produces a compound obtainable by means of the process according to the invention and processes the said compound in situ. In the preferred embodiment, one starts
from those starting materials which lead to the compounds described above as preferred.

The compounds of formula I-X, including their salts, are also obtainable in the form of hydrates, or their crystals can include for example the solvent used for crystallization (present as solvates).

New starting materials and/or intermediates, as well as processes for the preparation thereof, are likewise the subject of this invention. In the preferred embodiment, such starting materials are used and reaction conditions so selected as to enable the preferred compounds to be obtained.

Starting materials of the invention, are known, are commercially available, or can be synthesized in analogy to or according to methods that are known in the art.

For example, amine 1 can be prepared by reduction of the corresponding nitro. The reduction preferably takes place in the presence of a suitable reducing agent, such as tin(II) chloride or hydrogen in the presence of an appropriate catalyst, such as Raney nickel (then preferably the hydrogen is used under pressure, e.g. between 2 and 20 bar) or Pt02, in an appropriate solvent, e.g. an alcohol, such as MeOH. The reaction temperature is preferably between about 0°C and about 80°C, especially about 15°C to about 30°C.

It would also be possible to reduce the nitro compound after forming the amide compound under reaction conditions analogous to those for the reduction of nitro compounds described above. This would eliminate the need to protect the free amino group as described in Scheme 1.

In the preparation of starting materials, existing functional groups which do not participate in the reaction should, if necessary, be protected. Preferred protecting
groups, their introduction and their removal are described above or in the examples.

All remaining starting materials are known, capable of being prepared according to known processes, or commercially obtainable; in particular, they can be prepared using processes as described in the examples.

Compounds of the present invention can possess, in general, one or more asymmetric carbon atoms and are thus capable of existing in the form of optical isomers as well as in the form of racemic or non-racemic mixtures thereof. The optical isomers can be obtained by resolution of the racemic mixtures according to conventional processes, e.g., by formation of diastereoisomeric salts, by treatment with an optically active acid or base. Examples of appropriate acids are tartaric, diacetyltartaric, dibenzoyletartaric, ditoluyltartaric, and camphorsulfonic acid and then separation of the mixture of diastereoisomers by crystallization followed by liberation of the optically active bases from these salts. A different process for separation of optical isomers involves the use of a chiral chromatography column optimally chosen to maximize the separation of the enantiomers. Still another available method involves synthesis of covalent diastereoisomeric molecules by reacting compounds of the invention with an optically pure acid in an activated form or an optically pure isocyanate. The synthesized diastereoisomers can be separated by conventional means such as chromatography, distillation, crystallization or sublimation, and then hydrolyzed to deliver the enantiomerically pure compound.

The optically active compounds of the invention can likewise be obtained by using optically active starting materials. These isomers may be in the form of a free acid, a free base, an ester or a salt.
The compounds of this invention may contain one or more asymmetric centers and thus occur as racemates and racemic mixtures, scalemic mixtures, single enantiomers, individual diastereomers and diastereomeric mixtures. All such isomeric forms of these compounds are expressly included in the present invention.

The compounds of this invention may also be represented in multiple tautomeric forms, for example, as illustrated below:

```
  \[ \text{H} \quad \text{H} \]
  \[ \text{N} \quad \text{N} \]
```

The invention expressly includes all tautomeric forms of the compounds described herein.

The compounds may also occur in cis- or trans- or E- or Z- double bond isomeric forms. All such isomeric forms of such compounds are expressly included in the present invention. All crystal forms of the compounds described herein are expressly included in the present invention.

Substituents on ring moieties (e.g., phenyl, thieryl, etc.) may be attached to specific atoms, whereby they are intended to be fixed to that atom, or they may be drawn unattached to a specific atom, whereby they are intended to be attached at any available atom that is not already substituted by an atom other than H (hydrogen).

The compounds of this invention may contain heterocyclic ring systems attached to another ring system. Such heterocyclic ring systems may be attached through a carbon atom or a heteroatom in the ring system.

Alternatively, a compound of any of the formulas delineated herein may be synthesized according to any of the processes delineated herein. In the processes delineated
herein, the steps may be performed in an alternate order and may be preceded, or followed, by additional protection/deprotection steps as necessary. The processes may further comprise use of appropriate reaction conditions, including inert solvents, additional reagents, such as bases (e.g., LDA, DIEA, pyridine, K₂CO₃, and the like), catalysts, and salt forms of the above. The intermediates may be isolated or carried on in situ, with or without purification. Purification methods are known in the art and include, for example, crystallization, chromatography (liquid and gas phase, simulated moving bed ("SMB")), extraction, distillation, trituration, reverse phase HPLC and the like. Reactions conditions such as temperature, duration, pressure, and atmosphere (inert gas, ambient) are known in the art and may be adjusted as appropriate for the reaction.

As can be appreciated by the skilled artisan, the above synthetic schemes are not intended to comprise a comprehensive list of all means by which the compounds described and claimed in this application may be synthesized. Further methods will be evident to those of ordinary skill in the art. Additionally, the various synthetic steps described above may be performed in an alternate sequence or order to give the desired compounds. Synthetic chemistry transformations and protecting group methodologies (protection and deprotection) useful in synthesizing the inhibitor compounds described herein are known in the art and include, for example, those such as described in R. Larock, *Comprehensive Organic Transformations*, VCH Publishers (1989); T.W. Greene and P.G.M. Wuts, *Protective Groups in Organic Synthesis*, 3rd. Ed., John Wiley and Sons (1999); L. Fieser and M. The compounds of this invention may be modified by appending appropriate functionalities to enhance selective biological properties. Such modifications are known in the art and include those which increase biological penetration into a given biological compartment (e.g., blood, lymphatic system, central nervous system), increase oral availability, increase solubility to allow administration by injection, alter metabolism and alter rate of excretion.

The following examples contain detailed descriptions of the methods of preparation of compounds of Formulas I-X. These detailed descriptions fall within the scope, and serve to exemplify, the above described General Synthetic Procedures which form part of the invention. These detailed descriptions are presented for illustrative purposes only and are not intended as a restriction on the scope of the invention.

Unless otherwise noted, all materials were obtained from commercial suppliers and used without further purification. Anhydrous solvents such as DMF, THF, CH₂Cl₂ and toluene were obtained from the Aldrich Chemical Company. All reactions involving air- or moisture-sensitive compounds were performed under a nitrogen atmosphere. Flash chromatography was performed using Aldrich Chemical Company silica gel (200-400 mesh, 60A) or Biotage pre-packed column. Thin-layer chromatography (TLC) was performed with Analtech gel TLC plates (250 μ). Preparative TLC was performed with Analtech-silica gel plates (1000-2000 μ). Preparative HPLC
was conducted on a Beckman or Waters HPLC system with 0.1% TFA/H₂O and 0.1% TFA/CH₃CN as mobile phase. The flow rate was at 20 ml/min. and gradient method was used. ¹H NMR spectra were determined with super conducting FT NMR spectrometers operating at 400 MHz or a Varian 300 MHz instrument. Chemical shifts are expressed in ppm downfield from internal standard tetramethyldisilane. All compounds showed NMR spectra consistent with their assigned structures. Mass spectra (MS) were determined on a Perkin Elmer - SCIEX API 165 electrospray mass spectrometer (positive and, or negative) or an HP 1100 MSD LC-MS with electrospray ionization and quadrupole detection. All parts are by weight and temperatures are in Degrees centigrade unless otherwise indicated.

Preparation I - 3-nitro-5-trifluoromethyl-phenol

1-Methoxy-3-nitro-5-trifluoromethyl-Benzene (10g, Aldrich)
and pyridine-HCl (41.8g, Aldrich) were mixed together and
heated neat at 210°C in an open flask. After 2.5 h the
mixture was cooled to RT and partitioned between 1N HCl and
EtOAc. The EtOAc fraction was washed with 1N HCl (4x), brine
(1x), dried with Na₂SO₄, filtered and concentrated in vacuo
to form 3-nitro-5-trifluoromethyl-phenol as an off-white
solid.

Preparation II - 1-Boc-4-(3-nitro-5-trifluoromethyl-
phenoxy)-piperidine

3-Nitro-5-trifluoromethyl-phenol (8.81g) was dissolved in
THF (76 ml). 1-Boc-4-hydroxy-piperidine (8.81 g, Aldrich)
and Ph₃P (11.15 g) were added and the solution was cooled to
-20°C. A solution of DEAD (6.8 ml, Aldrich) in THF (36 ml)
was added dropwise, maintaining the temperature between -20
and -10°C. The reaction was warmed to RT and stirred
overnight. The reaction was concentrated in vacuo and
triturated with hexane. The yellow solid was removed by
filtration and washed with Et₂O (25 ml), and hexane. The
white filtrate was washed with 1N NaOH (2x), brine (1x) and
the hexane layer was dried over Na₂SO₄, filtered and concentrated in vacuo. The crude material was purified with flash chromatography (SiO₂, 5-10% EtOAc/hexane) to obtain 1-Boc-4-(3-nitro-5-trifluoromethyl-phenoxy)-piperidine.

The following compounds were prepared similarly to the procedure outlined above:

a) (S)-1-Boc-[2-(5-nitro-2-trifluoromethylphenoxy)methyl]-pyrrolidine

**Example 53**

![Chemical Structure](attachment:image.png)

[2-(1H-Indazol-6-ylamino)(3-pyridyl)]-N-[4-(1-methyl(4-piperidyl))phenyl]carboxamide
Step A: Preparation of 4-phenylpiperidine

4-Cyano-4-phenylpiperidine hydrochloride (10.0 g, 45.0 mmol) was combined with KOH pellets and stirred vigorously under Ar at 160°C for 4 h. The reaction mix was cooled to RT and dissolved into toluene (100 ml) and H2O (100 ml). After separation of the layers, the aqueous layer was back-extracted two times with toluene. The combined organic layer was dried over Na2SO4, concentrated in vacuo, and dried under high vacuum, yielding a white solid.

Step B: Preparation of 1-methyl-4-phenylpiperidine

To a stirring mixture at ambient temperature of 4-phenylpiperidine (5.24 g, 32.48 mmol, Step A) in CH3CN (95 ml) was added a 37% solution of HCHO in H2O (13 ml). To this mixture was added NaCNBH3 (3.27 g, 51.97 mmol). AcOH was added dropwise every 10 min over the next h to maintain the reaction pH near 7. The reaction volume was then reduced in vacuo. The reaction mix was diluted with CH2Cl2 and washed with 2N NaOH and then brine. The crude was concentrated in vacuo and eluted through a silica gel column with 10% MeOH/CH2Cl2. The 1-methyl-4-phenylpiperidine was concentrated in vacuo, yielding a clear oil.

Step C: Preparation of 4-(1-methyl-4-piperidyl)phenylamine

To 1-methyl-4-phenylpiperidine (2.663 g, 15.19 mmol, Step B) was added carefully H2SO4 (15.2 ml). The reaction was cooled in an ice bath and a solution of H2SO4 (1.66 ml) and fuming HNO3 (0.67 ml, 15.95 mmol) was added dropwise over 45 min. The mix was stirred at 0°C for 3 h then at RT for 1.5 h before being poured over about 90 g ice and basified with 24 g solid NaOH. The mix was extracted with CH2Cl2. The organic layer was washed with H2O, dried over Na2SO4, and concentrated in vacuo. The crude was eluted on
a silica gel column with a MeOH/CH₂Cl₂ gradient to yield 1-methyl-4-(4-nitrophenyl)piperidine which was hydrogenated under H₂ to furnish the title compound.

**Step D: Preparation of [2-(1H-indazol-6-ylamino)(3-pyridyl)]-N-[4-(1-methyl(4-piperidyl))phenyl]carboxamide**

The title compound was analogously synthesized by the method described in Example 43 from 4-(1-methyl-4-piperidyl)phenylamine (Step C). MS: 427.0 (M+1). Calc'd. for C₂₅H₂₈N₆O - 426.5.

**N-[4-(tert-Butyl)-3-(3-piperidylpropyl)phenyl][2-(1H-indazol-6-ylamino)(3-pyridyl)]carboxamide**

**Step A: Preparation of 1-piperidylprop-2-en-1-one**

To a 0°C solution of acryloyl chloride (4.576 g, 50.558 mmol) in CH₂Cl₂ (50 ml) was added dropwise and very carefully piperidine (4.305 g, 50.558 mmol). The reaction flask was vented during the exothermic addition. After the addition was completed, the white slurry was stirred at 0°C for 40 min and at RT for 1 h. The reaction was diluted with 70 ml CH₂Cl₂ and washed first with about 60 ml 2N HCl and then with about 60 ml of a mix of 2N NaOH and brine. The organic layer was dried over Na₂SO₄. The solution was evaporated by heating in a water bath at 60°C without
vacuum. Once most solvent had been evaporated off, dried the clear oil under high vacuum at RT for 30 min.

**Step B: Preparation of 1-( tert-butyl)-2-bromo-4-nitrobenzene**

Bromine (17.4 ml) was added dropwise over 40 min to a stirred mixture of 4-tert-butylnitrobenzene (59.5 g, 332 mmol), silver(II)sulfate (56.5 g, 181 mmol), H$_2$SO$_4$ (300 ml), and H$_2$O (33 ml) at RT. The mixture was stirred for a further 3 h and then poured into 0.1 M Na$_2$S$_2$O$_5$/H$_2$O (1L). The solid was filtered, washed with H$_2$O, Et$_2$O, and CH$_2$Cl$_2$. The filtrate layers were separated. The aqueous fraction was extracted with Et$_2$O. The combined organic layers were combined, dried over Na$_2$SO$_4$, and concentrated in vacuo. The yellow solid was triturated with hexanes to give a pale yellow crystalline solid.

**Step C: Preparation of (2E)-3-[2-( tert-butyl)-5-nitrophenyl]-1-piperidylprop-2-en-1-one**

To this solution was added Pd(OAc)$_2$ (60 mg, 0.267 mmol) and Pd(PPh$_3$)$_4$ (617 mg, 0.5335 mmol). The mix was degassed with N$_2$ and heated in a sealed vessel at 120°C for 15 h. The reaction mixture was cooled to RT, filtered, and concentrated in vacuo. The dark crude oil was eluted through a silica gel column with 15% to 22% EtOAc/hexanes gradient system to yield a thick amber oil as the title compound.

The reaction was not complete the next day, so the reaction was continued for an additional 20 h with fresh catalyst. The mix was filtered through Celite® and concentrated in vacuo to give a foamy oil.

**Step E: Preparation of 4-(tert-butyl)-3-(3-piperidylpropyl)phenylamine**

3-(5-Amino-2-tert-butylphenyl)-1-piperidin-1-yl-propenone (2.312 g, 7.619 mmol, from above step) was dissolved in THF (100 ml) at RT. To this solution was added LiAlH₄ (434 mg, 11.43 mmol). \(N-[3-(2\text{-}\text{Bromo-ethylamino})\text{-}4\text{-}\text{tert-butyl-phenyl}]\text{-}2-(1\text{H-indazol}-6-ylamino)\text{-}nicotinamide\) was dissolved in DMF (2 ml)
morpholine (0.09 ml) was added and stirred overnight at RT. The mixture was partitioned between sat'd NaHCO3 and EtOAc. The aqueous layer was extracted with EtOAc and the organic layers were washed with H2O, brine and dried (MgSO4). The crude material was purified by flash chromatography (5% MeOH/ CH2Cl2) to yield a yellow foamed solid. MS (ES+): 514 (M+H), Calc'd for C23H31N7O2 - 513.6.

Although the pharmacological properties of the compounds of Formula I-X vary with structural change, in general, activity possessed by compounds of Formula I-X may be demonstrated in vivo. The pharmacological properties of the compounds of this invention may be confirmed by a number of pharmacological in vitro assays. The exemplified pharmacological assays which follow have been carried out with the compounds according to the invention and their salts. Compounds of the present invention showed inhibition of KDR at doses less than 50 \mu m.
BIOLOGICAL EVALUATION

HUVEC Proliferation Assay

Human Umbilical Vein Endothelial cells are purchased from Clonetics, Inc., as cryopreserved cells harvested from a pool of donors. These cells, at passage 1, are thawed and expanded in EBM-2 complete medium, until passage 2 or 3. The cells are trypsinized, washed in DMEM + 10% FBS + antibiotics, and spun at 1000 rpm for 10 min. Prior to centrifugation of the cells, a small amount is collected for a cell count. After centrifugation, the medium is discarded, and the cells are resuspended in the appropriate volume of DMEM + 10% FBS + antibiotics to achieve a concentration of 3x10^5 cells/mL. Another cell count is performed to confirm the cell concentration. The cells are diluted to 3x10^4 cells/mL in DMEM + 10% FBS + antibiotics, and 100 µL of cells are added to a 96-well plate. The cells are incubated at 37°C for 22 h.

Prior to the completion of the incubation period, compound dilutions are prepared. Five-point, five-fold serial dilutions are prepared in DMSO, at concentrations 400-fold greater than the final concentrations desired. 2.5 µL of each compound dilution are diluted further in a total of 1 mL DMEM + 10% FBS + antibiotics (400x dilution). Medium containing 0.25% DMSO is also prepared for the 0 µM compound sample. At the 22-hour timepoint, the medium is removed from the cells, and 100 µL of each compound dilution is added. The cells are incubated at 37°C for 2-3 h.

During the compound pre-incubation period, the growth factors are diluted to the appropriate concentrations. Solutions of DMEM + 10% FBS + antibiotics, containing either VEGF or bFGF at the following concentrations: 50, 10, 2, 0.4, 0.08, and 0 ng/mL are prepared. For the compound-
treated cells, solutions of VEGF at 550 ng/mL or bFGF at 220 ng/mL for 50 ng/mL or 20 ng/mL final concentrations, respectively, are prepared since 10 μL of each will be added to the cells (110 μL final volume). At the appropriate time after adding the compounds, the growth factors are added. VEGF is added to one set of plates, while bFGF is added to another set of plates. For the growth factor control curves, the media on wells B4-G6 of plates 1 and 2 are replaced with media containing VEGF or bFGF at the varying concentrations (50 - 0 ng/mL). The cells are incubated at 37°C for an additional 72 h.

At the completion of the 72 h incubation period, the medium is removed, and the cells are washed twice with PBS. After the second wash with PBS, the plates are tapped gently to remove excess PBS, and the cells are placed at -70°C for at least 30 min. The cells are thawed and analyzed using the CyQuant fluorescent dye (Molecular Probes C-7026), following the manufacturer’s recommendations. The plates are read on a Victor/Wallac 1420 workstation at 485 nm/530 nm (excitation/emission). Raw data are collected and analyzed using a 4-parameter fit equation in XLFit. IC50 values are then determined.

**Angiogenesis Model**

To determine the effects of the present compounds on angiogenesis in vivo, selective compounds are tested in the rat corneal neovascularization micropocket model or the

**Rat Corneal Neovascularization Micropocket Model**

*In Life Aspects:* Female Sprague Dawley rats weighing approximately 250 g were randomized into one of five treatment groups. Pretreatment with the vehicle or compound was administered orally, 24 h prior to surgery and continued once a day for seven additional days. On the day of surgery, the rats were temporarily anesthetized in an Isoflurane gas chamber (delivering 2.5 liters/min oxygen + 5% Isoflurane). An othoscope was then placed inside the mouth of the animal to visualize the vocal cords. A tip-blunted wire was advanced in between the vocal cords and used as a guide for the placement of an endotracheal Teflon tube (Small Parts Inc. TFE-standard Wall R-SWTT-18). A volume-controlled ventilator (Harvard Apparatus, Inc. Model 683) was connected to the endotracheal tube to deliver a mixture of oxygen and 3% Isoflurane. Upon achieving deep anesthesia, the whiskers were cut short and the eye areas and eyes gently washed with Betadine soap and rinsed with sterile saline. The corneas were irrigated with one to two drops of Proparacaine HCl ophthalmic topical anesthetic solution (0.5%) (Bausch and Lomb Pharmaceuticals, Tampa FL).

The rat was then positioned under the dissecting microscope and the corneal surface brought into focus. A vertical incision was made on the midline of the cornea using a diamond blade knife. A pocket was created by using fine scissors to separate the connective tissue layers of the stroma, tunneling towards the limbus of the eye. The distance between the apex of the pocket and the limbus was approximately 1.5 mm. After the pocket had been made, the soaked nitrocellulose disk filter (Gelman Sciences, Ann Arbor MI.) was inserted under the lip of the pocket. This
surgical procedure was performed on both eyes. rhU-bFGF soaked disks were placed into the right eye, and the rhU-VEGF soaked disks were placed into the left eye. Vehicle soaked disks were placed in both eyes. The disk was pushed into position at the desired distance from the limbal vessels. Ophthalmic antibiotic ointment was applied to the eye to prevent drying and infection. After seven days, the rats were euthanized by CO₂ asphyxiation, and the eyes enucleated. The retinal hemisphere of the eye was windowed to facilitate fixation, and the eye placed into formalin overnight.

Post Mortem Aspects: After twenty-four hours in fixative, the corneal region of interest was dissected out from the eye, using fine forceps and a razorblade. The retinal hemisphere was trimmed off and the lens extracted and discarded. The corneal dome was bisected and the superfluous cornea trimmed off. The iris, conjunctiva and associated limbal glands were then carefully teased away. Final cuts were made to generate a square 3x3mm containing the disk, the limbus, and the entire zone of neovascularization.

Gross Image Recording: The corneal specimens were digitally photographed using a Sony CatsEye DKC5000 camera (A.G. Heinz, Irvine CA) mounted on a Nikon SMZ-U stereo microscope (A.G. Heinz). The corneas were submerged in distilled water and photographed via trans-illumination at approximately 5.0 diameters magnification.

Image analysis: Numerical endpoints were generated using digital micrographs collected from the whole mount corneas after trimming and were used for image analysis on the Metamorph image analysis system (Universal Imaging Corporation, West Chester PA). Three measurements were taken: Disk placement distance from the limbus, number of vessels intersecting a 2.0mm perpendicular line at the
midpoint of the disk placement distance, and percent blood vessel area of the diffusion determined by thresholding.

**General Formulations:**

**0.1% BSA in PBS vehicle:** 0.025 g of BSA was added to 25.0 ml of sterile 1X phosphate buffered saline, gently shaken until fully dissolved, and filtered at 0.2 μm. Individual 1.0 ml samples were aliquoted into 25 single use vials, and stored at -20°C until use. For the rHu-bFGF disks, a vial of this 0.1% BSA solution was allowed to thaw at room temperature. Once thawed, 10 μl of a 100 mM stock solution of DTT was added to the 1 ml BSA vial to yield a final concentration of 1 mM DTT in 0.1% BSA.

**rHu-VEGF Dilutions:**

Prior to the disk implant surgery, 23.8 μl of the 0.1% BSA vehicle above was added to a 10 μg rHu-VEGF lyophilized vial yielding a final concentration of 10 μM.

**rHu-bFGF: Stock concentration of 180 ng/μl:**

R&D rHu-bFGF: Added 139 μl of the appropriate vehicle above to the 25 μg vial lyophilized vial. 13.3 μl of the [180 ng/μl] stock vial and added 26.6 μl of vehicle to yield a final concentration of 3.75 μM concentration.

**Nitro-cellulose disk preparation:** The tip of a 20-gauge needle was cut off square and beveled with emery paper to create a punch. This tip was then used to cut out 0.5mm diameter disks from a nitrocellulose filter paper sheet (Gelman Sciences). Prepared disks were then placed into Eppendorf microfuge tubes containing solutions of either 0.1% BSA in PBS vehicle, 10 μM rHu-VEGF (R&D Systems, Minneapolis, MN), or 3.75 μM rHu-bFGF (R&D Systems, Minneapolis, MN) and allowed to soak for 45-60 min before use. Each nitrocellulose filter disk absorbs approximately 0.1 μl of solution.
In the rat micropocket assay, compounds of the present invention will inhibit angiogenesis at a dose of less than 50 mg/kg/day.

Tumor model

A431 cells (ATCC) are expanded in culture, harvested and injected subcutaneously into 5-8 week old female nude mice (CD1 nu/nu, Charles River Labs) (n=5-15). Subsequent administration of compound by oral gavage (10 - 200 mpk/dose) begins anywhere from day 0 to day 29 post tumor cell challenge and generally continues either once or twice a day for the duration of the experiment. Progression of tumor growth is followed by three dimensional caliper measurements and recorded as a function of time. Initial statistical analysis is done by repeated measures analysis of variance (RMANOVA), followed by Scheffe post hoc testing for multiple comparisons. Vehicle alone (Ora-Plus, pH 2.0) is the negative control. Compounds of the present invention are active at doses less than 150 mpk.

Rat Adjuvant Arthritis Model:

The rat adjuvant arthritis model (Pearson, Proc. Soc. Exp. Biol. 91, 95-101 (1956)) is used to test the anti-arthritic activity of compounds of the formula 1, or salts thereof. Adjuvant Arthritis can be treated using two different dosing schedules: either (i) starting time of immunization with adjuvant (prophylactic dosing); or from day 15 when the arthritic response is already established (therapeutic dosing). Preferably a therapeutic dosing schedule is used.
Rat Carrageenan-induced Analgesia Test

The rat carrageenan analgesia test was performed with materials, reagents and procedures essentially as described by Hargreaves, et al., (Pain, 32, 77 (1988)). Male Sprague-Dawley rats were treated as previously described for the Carrageenan Foot Pad Edema test. Three hours after the injection of the carrageenan, the rats were placed in a special plexiglass container with a transparent floor having a high intensity lamp as a radiant heat source, positionable under the floor. After an initial twenty minute period, thermal stimulation was begun on either the injected foot or on the contralateral uninjected foot. A photoelectric cell turned off the lamp and timer when light was interrupted by paw withdrawal. The time until the rat withdraws its foot was then measured. The withdrawal latency in seconds was determined for the control and drug-treated groups, and percent inhibition of the hyperalgesic foot withdrawal determined.

Formulations

Also embraced within this invention is a class of pharmaceutical compositions comprising the active compounds of Formula I-X in association with one or more non-toxic, pharmaceutically-acceptable carriers and/or diluents and/or adjuvants (collectively referred to herein as "carrier" materials) and, if desired, other active ingredients. The active compounds of the present invention may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. The compounds and compositions of the present invention may, for example, be administered orally, mucosally, topically,
rectally, pulmonarily such as by inhalation spray, or parentally including intravascularly, intravenously, intraperitoneally, subcutaneously, intramuscularly intrasternally and infusion techniques, in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants, and vehicles.

The pharmaceutically active compounds of this invention can be processed in accordance with conventional methods of pharmacy to produce medicinal agents for administration to patients, including humans and other mammals.

For oral administration, the pharmaceutical composition may be in the form of, for example, a tablet, capsule, suspension or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a particular amount of the active ingredient. Examples of such dosage units are tablets or capsules. For example, these may contain an amount of active ingredient from about 1 to 2000 mg, preferably from about 1 to 500 mg or 5 to 1000 mg. A suitable daily dose for a human or other mammal may vary widely depending on the condition of the patient and other factors, but, once again, can be determined using routine methods.

The amount of compounds which are administered and the dosage regimen for treating a disease condition with the compounds and/or compositions of this invention depends on a variety of factors, including the age, weight, sex and medical condition of the subject, the type of disease, the severity of the disease, the route and frequency of administration, and the particular compound employed. Thus, the dosage regimen may vary widely, but can be determined routinely using standard methods. A daily dose of about 0.01 to 500 mg/kg, preferably between about 0.1 and about 50 mg/kg, and more preferably about 0.1 and about 20 mg/kg
body weight may be appropriate. The daily dose can be administered in one to four doses per day.

For therapeutic purposes, the active compounds of this invention are ordinarily combined with one or more adjuvants appropriate to the indicated route of administration. If administered per os, the compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanoic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium and calcium salts of phosphoric and sulfuric acids, gelatin, acacia gum, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and then tableted or encapsulated for convenient administration. Such capsules or tablets may contain a controlled-release formulation as may be provided in a dispersion of active compound in hydroxypropylmethyl cellulose.

In the case of psoriasis and other skin conditions, it may be preferable to apply a topical preparation of compounds of this invention to the affected area two to four times a day.

Formulations suitable for topical administration include liquid or semi-liquid preparations suitable for penetration through the skin (e.g., liniments, lotions, ointments, creams, or pastes) and drops suitable for administration to the eye, ear, or nose. A suitable topical dose of active ingredient of a compound of the invention is 0.1 mg to 150 mg administered one to four, preferably one or two times daily. For topical administration, the active ingredient may comprise from 0.001% to 10% w/w, e.g., from 1% to 2% by weight of the formulation, although it may comprise as much as 10% w/w, but preferably not more than 5% w/w, and more preferably from 0.1% to 1% of the formulation.
When formulated in an ointment, the active ingredients may be employed with either paraffinic or a water-miscible ointment base. Alternatively, the active ingredients may be formulated in a cream with an oil-in-water cream base. If desired, the aqueous phase of the cream base may include, for example at least 30% w/w of a polyhydric alcohol such as propylene glycol, butane-1,3-diol, mannitol, sorbitol, glycerol, polyethylene glycol and mixtures thereof. The topical formulation may desirably include a compound which enhances absorption or penetration of the active ingredient through the skin or other affected areas. Examples of such dermal penetration enhancers include DMSO and related analogs.

The compounds of this invention can also be administered by a transdermal device. Preferably transdermal administration will be accomplished using a patch either of the reservoir and porous membrane type or of a solid matrix variety. In either case, the active agent is delivered continuously from the reservoir or microcapsules through a membrane into the active agent permeable adhesive, which is in contact with the skin or mucosa of the recipient. If the active agent is absorbed through the skin, a controlled and predetermined flow of the active agent is administered to the recipient. In the case of microcapsules, the encapsulating agent may also function as the membrane.

The oily phase of the emulsions of this invention may be constituted from known ingredients in a known manner. While the phase may comprise merely an emulsifier, it may comprise a mixture of at least one emulsifier with a fat or an oil or with both a fat and an oil. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make-up the
so-called emulsifying wax, and the wax together with the oil and fat make up the so-called emulsifying ointment base which forms the oily dispersed phase of the cream formulations. Emulsifiers and emulsion stabilizers suitable for use in the formulation of the present invention include Tween 60, Span 80, cetostearyl alcohol, myristyl alcohol, glycercyl monostearate, sodium lauryl sulfate, glycercyl distearate alone or with a wax, or other materials well known in the art.

The choice of suitable oils or fats for the formulation is based on achieving the desired cosmetic properties, since the solubility of the active compound in most oils likely to be used in pharmaceutical emulsion formulations is very low. Thus, the cream should preferably be a non-greasy, non-staining and washable product with suitable consistency to avoid leakage from tubes or other containers. Straight or branched chain, mono- or dibasic alkyl esters such as di-isoadipate, isocetyl stearate, propylene glycol diester of coconut fatty acids, isopropyl myristate, decyl oleate, isopropyl palmitate, butyl stearate, 2-ethylhexyl palmitate or a blend of branched chain esters may be used. These may be used alone or in combination depending on the properties required. Alternatively, high melting point lipids such as white soft paraffin and/or liquid paraffin or other mineral oils can be used.

Formulations suitable for topical administration to the eye also include eye drops wherein the active ingredients are dissolved or suspended in suitable carrier, especially an aqueous solvent for the active ingredients. The active ingredients are preferably present in such formulations in a concentration of 0.5 to 20%, advantageously 0.5 to 10% and particularly about 1.5% w/w.
Formulations for parenteral administration may be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions may be prepared from sterile powders or granules using one or more of the carriers or diluents mentioned for use in the formulations for oral administration or by using other suitable dispersing or wetting agents and suspending agents. The compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, tragacanth gum, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art. The active ingredient may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water, or with cyclodextrin (ie. Captisol), cosolvent solubilization (ie. propylene glycol) or micellar solubilization (ie. Tween 80).

The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer’s solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed, including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

For pulmonary administration, the pharmaceutical composition may be administered in the form of an aerosol or with an inhaler including dry powder aerosol.

Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable non-
irritating excipient such as cocoa butter and polyethylene glycols that are solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum and release the drug.

The pharmaceutical compositions may be subjected to conventional pharmaceutical operations such as sterilization and/or may contain conventional adjuvants, such as preservatives, stabilizers, wetting agents, emulsifiers, buffers etc. Tablets and pills can additionally be prepared with enteric coatings. Such compositions may also comprise adjuvants, such as wetting, sweetening, flavoring, and perfuming agents.

The foregoing is merely illustrative of the invention and is not intended to limit the invention to the disclosed compounds. Variations and changes which are obvious to one skilled in the art are intended to be within the scope and nature of the invention which are defined in the appended claims.

From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.

All mentioned references, patents, applications and publications, are hereby incorporated by reference in their entirety, as if here written.
