Abstract: A device and method for a minimally invasive surgical implantation to reduce radicular symptoms by inserting an expandable cervical distraction implant in the facet joint and distracting the adjacent cervical vertebrae to increase the foraminal dimension. The implant, when positioned in the cervical facet joint, expands to via delivery of an inflation medium to increase the space between the vertebrae, thereby increasing the foraminal area or dimension, and reducing pressure on the nerves and blood vessels of the cervical spine.

BACKGROUND OF THE INVENTION

1. Field of the Invention

[0005] This invention pertains generally to an implantable distraction device, and more particularly to a cervical distraction device.

2. Description of Related Art

[0006] Chronic back problems cause pain and disability for a large segment of the population. Adverse spinal conditions are characteristic of age. With
aging, generally comes an increase in spinal stenosis (including, but not limited to, central canal and lateral stenosis), and facet arthropathy. Spinal stenosis results in a reduction of foraminal area (i.e., the available space for the passage of nerves and blood vessels) which compresses the cervical nerve roots and causes radicular pain. Extension and ipsilateral rotation of the neck further reduces the foraminal area and contributes to pain, nerve root compression, and neural injury. However, neck flexion generally increases the foraminal area.

[0007] Cervical disc herniations predominantly present with upper extremity radicular symptoms. The vast majority of these herniations do not have an associated neurologic deficit and present with pain only. A well-described treatment for cervical disc herniations is closed traction. There are a number of marketed devices that alleviate pain by pulling on the head to increase foraminal height.

[0008] Cervical disc herniations have been treated with anterior and posterior surgery. The vast majority of these surgeries are performed through an anterior approach, which requires a spinal fusion. These surgeries are expensive and beget additional surgeries due to change in biomechanics of the neck. There is a 3% incidence of re-operation after cervical spine surgery.

[0009] Therefore, an object of the present invention is to provide a minimally invasive device and surgery to increase foraminal height reduce radicular symptoms for patients with disc herniations.

[0010] At least some of these objectives will be met in the following disclosure.

BRIEF SUMMARY OF THE INVENTION

[0011] A device and technique are disclosed for a minimally invasive surgical implantation to reduce radicular symptoms by inserting an expandable cervical distraction implant in the facet joint at an affected level to preserve the physiology of the spine. In particular, embodiments of the present invention provide for distracting the cervical spine to increase the foraminal dimension in extension and neutral positions. The implant of the present invention, when positioned in the cervical facet joint, expands to distract, or increase the space
between, the vertebrae to increase the foraminal area or dimension, and reduce pressure on the nerves and blood vessels of the cervical spine.

The procedure may be performed under conscious sedation in order to obtain intra-operative patient symptom feedback.

When the distraction implant is optimally positioned in the facet joint, it is injected with a bio-inert hydrogel using a catheter inflation syringe with pressure/volume monitor. The injection of the hydrogel causes the implant to expand in order to achieve cervical distraction. At this point in the procedure, patient feedback regarding symptom improvement could be obtained.

After achieving the desired distraction, the catheter is detached from the distraction implant and be removed. The patient is left with the distraction implant expanded in the facet joint with permanent increased foraminal height.

Aspect of the invention is an apparatus for distracting first and second adjacent vertebrae. The apparatus has an expandable implant configured to be inserted in a collapsed configuration within a facet joint bounded by the first and second vertebrae, and expand within the facet joint to increase a foraminal dimension, e.g. foraminal height associated with the first and second adjacent vertebrae.

Preferably, the expandable implant is configured to be installed in a facet joint located between at least one cervical vertebra. However, other locations are contemplated.

In one embodiment, the expandable implant is configured to engage the articulating surfaces of the facet joint to increase the distance between the articulating surfaces, the distance correlating to the foraminal dimension.

The expandable implant may comprises an inflatable balloon configured to be filled with an inflation medium, e.g. hydrogel or the like, to distribute a compressive load on the articulating surfaces.

Generally, the facet joint has a joint capsule that extends beyond the margin of the articulating surfaces. In a preferred embodiment, the expandable implant is configured to be delivered into the facet joint through an access hole created in the joint capsule. The expandable implant is ideally
configured such that, in its expanded configuration, is larger than the access hole so that the expandable implant is retained in the facet joint once expanded. The expandable implant may also be configured to plug the access hole once expanded. Typically, the expandable implant is configured to occupy a substantial portion of the depth of the facet joint once expanded.

In another preferred embodiment, the expandable implant is configured to dynamically stabilize the facet joint. Generally, the expandable implant increases and maintains a minimum distance between the articulating surfaces, while allowing motion of the first vertebrae with respect to the second vertebrae.

For delivery, the expandable implant preferably attaches to a distal tip of a catheter to facilitate installation into the facet joint. The catheter transports the inflation medium into the expandable implant. The expandable implant is configured to detach from the catheter once the implant is expanded in the facet joint.

Another aspect is a method of minimally invasively distracting first and second adjacent vertebrae. The method includes the steps of inserting an expandable implant, in a collapsed state, into a facet joint bounded by the first and second vertebrae, and expanding the expandable implant within the facet joint to increase a foraminal dimension associated with the first and second vertebrae.

In a preferred embodiment, the expandable implant is installed in a facet joint located between at least one cervical vertebra. The expandable implant engages the articulating surfaces of the facet joint to increase the distance between the articulating surfaces.

In many embodiments, inserting an expandable implant is achieved by creating an access hole through the joint capsule, and inserting the expandable implant in a collapsed configuration through the access hole and into the facet joint. Typically, the access hole is created with an introducer needle used to deliver the expandable member.

In a preferred embodiment, an inflatable balloon is filled with an inflation
medium causing the balloon to engage the articulating surfaces the
expandable implant. A compressive load is imparted on the articulating
surfaces to distract the first vertebra from the second vertebra.

[0026] To inflate the expandable implant, a catheter is fed through the access
hole and into the facet joint with the expandable implant attached to a distal tip
of a catheter. An inflation medium is then delivered into the expandable
implant via the catheter to inflate expandable implant with the inflation
medium. Once inflated, the expandable implant detaches from the catheter
once the implant is expanded in the facet joint.

[0027] Dynamic stabilization of the facet joint is affected as a result of the
expanded implant being disposed between the articulating surfaces of the
facet joint. The distance between the articulating surfaces is maintained while
allowing motion of the first vertebrae with respect to the second vertebrae.

[0028] In one embodiment, the extent of inflation of the expandable member is
determined via patient feedback while the expandable member is being
inflated.

[0029] Another aspect is a system for distracting a first vertebra from a second
adjacent vertebra. The system includes a catheter and an expandable implant
configured to be detachably installed in a collapsed configuration on the distal
tip of the catheter. The expandable implant and catheter are configured to be
inserted in into a facet joint bounded by the first and second vertebrae to
expand the expandable implant within the facet joint to increase a neural
foraminal height associated with the first and second vertebrae.

[0030] Further aspects of the invention will be brought out in the following
portions of the specification, wherein the detailed description is for the purpose
of fully disclosing preferred embodiments of the invention without placing
limitations thereon.

BRIEF DESCRIPTION OF THE SEVERAL
VIEWS OF THE DRAWING(S)

[0031] The invention will be more fully understood by reference to the following
drawings which are for illustrative purposes only:
FIG. 1 is a lateral view of two cervical vertebral members in a stenosed condition.

FIG. 2 is a view of an introducer needle being inserted into the facet joint of the vertebral members in accordance with the present invention.

FIG. 3 illustrates an implant of the present invention being inserted into the facet joint.

FIG. 4 illustrates the implant of FIG. 3 in an expanded configuration.

FIG. 5 illustrates the implant of FIG. 4 with the catheter detached from the implant and removed from the treatment site.

FIG. 6 is another view of the placement of the implant in the facet joint in accordance with the present invention.

FIG. 7 is an expanded view of the implant installed in a collapsed configuration on a catheter.

FIG. 8 illustrates the implant of FIG. 7 in an expanded configuration.

FIG. 9 illustrates an implant of the present invention having a circular cross-section.

FIG. 10 illustrates an implant of the present invention having an oval cross-section.

FIG. 11 illustrates an implant of the present invention having a rectangular cross-section.

FIG. 12 illustrates an implant of the present invention having 2-piece design.

FIG. 13 illustrates an implant of the present invention having a taper along its length.

DETAILED DESCRIPTION OF THE INVENTION

Referring more specifically to the drawings, for illustrative purposes the present invention is embodied in the apparatus generally shown in FIG. 2 through FIG. 13. It will be appreciated that the apparatus may vary as to configuration and as to details of the parts, and that the method may vary as to the specific steps and sequence, without departing from the basic concepts as disclosed herein.
FIG. 1 illustrates a simplified lateral view of a portion of the cervical spine 10. The basic biomechanical unit or motion segment of the spine consists of two adjacent vertebrae 12 and 14 and the three joint articular complex through which they move and are constrained in relation to one another. The spine articulations generally consist of an intervertebral disc 26 located between the vertebral bodies 26 of adjacent vertebrae 12, 14, and two facet joints 16 symmetrically located laterally from the sagittal plane at the posterior end of the vertebral bodies 26.

The facet joints 16 allow constrained spinal motion, while protecting the contained neural structures. From a kinematic viewpoint, the intervertebral facet joints 16 are highly constrained sliding planar articulations, lubricated by synovial fluid contained within the facet joint capsule 30. In the cervical spine, the geometry of the cervical vertebral bodies provides a high degree of protection for the neural elements by limiting normal motion of the spine to within physiologic limits. The upward inclination of the superior articular surfaces of the facet joints allows for considerable flexion and extension, as well as for lateral mobility.

Minimally invasive surgical access to the facet joint is well documented. Each vertebral segment comprises a spinous process 34 located at the posterior end of the vertebrae, with the vertebral body located anteriorly. Each vertebra comprises an inferior articular (or transverse) process 35 and the superior articular process 37 that form four posterior articulating, e.g. opposing subchondral, surfaces: two superior facets 18 and two inferior facets 16. The inferior facet 18 from the inferior articular process 35 of the upper vertebra 12 and the superior facet from the superior articular process 37 of the lower vertebra 14 form the facet joint 16 on each lateral side of the spine.

Located medial to the articular processes 37 and vertebral bodies 26 is an aperture, or intervertebral foramina 38, that serves as a nerve root canal for the spinal nerves and vessels that transmit signals from the spinal chord to respective locations in the body.

Each facet joint 16 is covered by a dense, elastic articular capsule 28,
which is attached just beyond the margins of the articular facets 18, 22. The inside of the capsule is lined by a synovial membrane (not shown) which secretes synovial fluid for lubricating the facet joint. The exterior of the joint capsule is surrounded by a capsular ligament (not shown), which may be temporarily repositioned to give access for insertion of the extendable implant of the present invention, described in further detail below. Thus, from a posterior-lateral approach, access to the facet joint 16 is relatively straightforward and well prescribed, as compared to other regions of the spine which present a higher likelihood of trauma and risk of permanent damage.

It should also be noted that FIG. 1 depicts cervical foraminal stenosis, e.g. loss of height between the adjacent vertebrae 12, 14. As a result of disc herniation and corresponding height loss, the nerve root canal 38, or intervertebral foraminal height, having a value $H_b$, is narrowed relative to that of healthy anatomy. This narrowing of the foraminal height $H_b$ often leads to compression of the spinal cord and nerve roots (not shown), causing radicular symptoms.

As a result of the stenosed foraminal height $H_b$, the height of the facet joint 16, or distance between subchondral articulating surfaces 18 and 22, is also narrowed, (shown as value $D_b$ in FIG. 1). This may pose complications in the facet joint 16 as well. However, more importantly, because the height of the disc will be relatively fixed, an increase in the facet joint height will also have a corresponding increase in foraminal height, as described in greater detail below.

FIGS. 2-6 show the methods and system 50 of the present invention for performing a minimally invasive procedure configured to distract one or more of the facet joints 16 of vertebrae 12, 14, thereby increasing the dimension of the neural foramen while retaining facet joint mobility. One of the major advantages of minimally invasive surgery is the ability to perform the procedure with minimal tissue trauma. Television image intensifier fluoroscopy may be used to provide guidance for surgeon placement of instrumentation and implants precisely to the desired anatomic target in the
facet joint 16. The radiographic landmarks are well taught and the relative
procedural difficulty of this technique is low.

[0054] Referring to FIG. 2, a standard discography introducer needle 44 (e.g.
approximately 21 gauge needle) is be inserted into the outer facet capsule 28
to create a perforation or access hole 32 into the facet joint cavity 30. Dye
may then be injected through the introducer needle 44 to fluoroscopically
confirm that the introducer needle 44 is in the facet joint cavity 30.

[0055] Referring now to FIG. 3, a catheter 52 having an expandable implant 60
coupled to the distal end 54 of the catheter 52, may then be guided over into
the facet joint cavity 30 through needle 44 such that the distal tip 42 of the
implant is located in the proper position in cavity 30.

[0056] Once the implant 60 is placed at the correct location of the facet joint
16, the implant is injected with a bio-inert hydrogel to inflate the catheter.
Inflation may be achieved with a catheter inflation syringe 56, and the pressure
and/or volume may be observed via monitor 58. Further visualization may be
achieved by including a contrast dye within the hydrogel. The hydrogel and
expandable balloon may be similar to the materials found in the HyperGlide
Occlusion Balloon Catheter by Micro Therapeutics, Inc., used for vascular
occlusions.

[0057] FIG. 4 illustrates the implant 60 in an expanded configuration within the
facet joint. As shown in FIG. 4, the hydrogel- inflated expandable implant 60
generates an outward compressive force \( F \) on the subchondral surfaces 18
and 22 to increase the distance between them to a desired treatment or
nominal value \( D_\tau \). This correspondingly increases the height of the
intervertebral foramin to a treatment or nominal value \( H_\tau \). The value of \( D_\tau \), and
resulting increase in \( H_\tau \) may be predetermined by the surgeon prior to the
surgery based on pre-op analysis of the patient's condition and anatomy,
and/or may also be iteratively devised by patient feedback of symptom
improvement during the procedure.

[0058] The size of implant 60 is configured to distract the joint and reverse
narrowing of the nerve root canal 38 and alleviate symptoms of cervical
stenosis. However, it is also within the scope of the present invention to size
the implant according to other spinal conditions, for example to correct for
cervical kyphosis or loss of cervical lordosis.

[0059] Once the desired inflation/distraction is achieved, the catheter 52 is
detached from the implant 60, and fed out of the patient's body. Referring now
to FIG. 5, the expanded implant 60 will occupy the joint cavity 30 such that it
will occlude the opening 32 in the facet capsule 28. Because the inflated
implant 60 is larger than the opening 32 caused by the violation of the joint by
the introducer needle 44, the implant 60 acts as a plug to close off the joint
cavity 30. In addition, because the implant is confined within the boundaries of
the joint cavity 30, including the facet surfaces 18, 22 and capsule 28, it will
remain in its installed position without further anchoring to hold the device in
place. Due to the properties of synovial joints and the configuration of the
implant 60, it is unlikely that the implant 60 will extrude from the joint once it
has been implanted. If further constraint is desired, the external walls of the
balloon may be fabricated to have a surface roughness or texture configured
to inhibit motion with respect to the walls 18, 22 of the facet joint.

[0060] If symmetrical distraction is desired between the adjacent vertebrae,
the procedure may be repeated for the second facet joint located between the
target vertebrae. However, it is contemplated that only one implant may be
necessary to alleviate radicular symptoms.

[0061] FIG. 6 illustrates a preferred placement of the implant 60 within the
facet joint 16. The average width of the cervical facet is approximately 9 mm.
The average depth of the cervical facet is also approximately 9 mm. The
preferred location of the capsule is generally the center third of the facet joint
cavity 30, as its approximate size will be about 3-4 mm in width, as shown in
FIG. 6. The length of the implant 60 will be approximately 8-9 mm, or roughly
the depth of the facet joint cavity 30, and therefore may preferably occupy all
or nearly all of the joint depth. Preferably, the implant 60 will be configured to
expand to up to a height of approximately 3 mm or more. It is appreciated that
the above sizing of the implant may vary accordingly to accommodate patient
anatomy, condition, or desired foraminal height increase or other preferences defined by the surgeon.

[0062] The size, configuration, and placement of implant 60 are configured to provide distraction of the facet joint, while also preserving the mobility between the adjacent vertebrae 12, 14. For example, translation of the articular surfaces 18, 22 with respect to each other (e.g. along the plane of the surfaces) is not restrained, while the undesired translation normal to the articular surfaces 18, 22, (e.g. collapsing), is inhibited. Additionally, the adjacent vertebrae 12, 14 are allowed to rotate about the long axis of the implant 60 with respect to each other, as well as rotate about the spinal column axis. Thus, the implant 60 of the present invention allows for dynamic stabilization and distraction of the facet joint to increase and maintain foraminal height.

[0063] FIG. 7 illustrates an expandable balloon implant 60 in a collapsed configuration and attached to distal end 54 of catheter 52. The walls 72 of the balloon may be folded over along the length L of the balloon to minimize the profile of the balloon 60.

[0064] FIG. 8 illustrates expandable balloon implant 60 in its expanded configuration. Balloon implant 60 is generally comprised of one or more exterior walls that are configured to hold and retain the inflatable medium, e.g. hydrogel. In some embodiments, the implant 60 may have a central lumen (not shown), emanating at proximal end 76, and terminating at distal end 74 through the length L of the balloon. The central lumen allows the implant 60 to be fed over a guide wire, or like device, to the target location in the facet joint

[0065] The proximal end 76 will also have a port 70 allowing flow of the inflation medium into the bladder of the balloon. This port 70 may be self-sealing, wherein the port automatically seals upon detaching catheter 52, or may incorporate a plug (not shown) or other sealing mechanism that may be fed over guide wire 40 to close and seal up port 70 once the catheter 52 is removed.
The cross section of the implant may comprise a variety of different shapes, as shown in FIGS. 9-12. In FIG. 9, balloon implant 80 comprises an outer wall 82 having a generally circular shape, thus creating a cylindrical structure across the length of the balloon. The thickness T of the external wall 82 is configured to withstand the compressive loads associated with the facet joint in the cervical spine, and may be varied accordingly. With the cylinder shape implant 80, the outer wall will generally contact and engage the facet surfaces 18, 22 in a line down the depth of the facet cavity 30. The diameter D of the outer wall 82 will be sized for the desired increase of the foraminal height, e.g. ranging from approximately 1 mm to over 3 mm.

As illustrated in 10, balloon implant 90 may comprise a elliptical or oval cross section, having a height H sized for desired increase of the foraminal height, and width W. A rectangular cross section may also be used, as shown with implant 100 of FIG. 11.

The implants 80, 90 and 100 may be fabricated by a number of methods currently available in the art. For example, the implant may be formed as a single piece structure over a mandrel (not shown) having varying cross section for the central lumen (if needed) and outer walls 82, 92, 102.

In an alternative embodiment shown in FIG. 12, the balloon 110 may comprise a bladder having upper wall 114 and lower wall 115 that are heat sealed at the sides 112.

As illustrated in FIG. 13, the balloon may also be tapered along its length to accommodate the anatomy of the facet joint 16, as seen with balloon 120, wherein the leading or distal end 124 has a smaller profile than the trailing or distal end 126.

The extendable implants above may comprise an elastic material, e.g. biocompatible polymer, which allows the implant to expand to a varying range in sizes. Alternatively, the implant may comprise an inelastic material that has a maximum inflation capacity, and wherein a number of predetermined sizes may be available to the surgeon according to the desired size determined by the surgeon.
The implant 60 will generally be sized to accommodate the geometry of the patient anatomy and target foraminal height. For cervical herniations, the implant 60 will typically be installed from the C4/C5 joint down to C7/T1 (95% of all cervical herniations occur at C5/6 & C6/7). The height of the implant 60 may range from approximately 1 mm to over 3 mm, depending on the patient anatomy. For the cylindrical-shaped balloon 80 of FIG. 9, the width will roughly equal the height. However, as shown in FIGS. 10-12, the width may be increased for the desired stabilizing effect.

Although the embodiments disclosed above are directed primarily to installation in the cervical facet joint, it is contemplated that the devices and methods may also be used to increase foraminal dimension in other regions of the spine, e.g. thoracic, lumbar, etc.

Although the description above contains many details, these should not be construed as limiting the scope of the invention but as merely providing illustrations of some of the presently preferred embodiments of this invention. Therefore, it will be appreciated that the scope of the present invention fully encompasses other embodiments which may become obvious to those skilled in the art, and that the scope of the present invention is accordingly to be limited by nothing other than the appended claims, in which reference to an element in the singular is not intended to mean "one and only one" unless explicitly so stated, but rather "one or more." All structural, chemical, and functional equivalents to the elements of the above-described preferred embodiment that are known to those of ordinary skill in the art are expressly incorporated herein by reference and are intended to be encompassed by the present claims. Moreover, it is not necessary for a device or method to address each and every problem sought to be solved by the present invention, for it to be encompassed by the present claims. Furthermore, no element, component, or method step in the present disclosure is intended to be dedicated to the public regardless of whether the element, component, or method step is explicitly recited in the claims. No claim element herein is to be construed under the provisions of 35 U.S.C. 112, sixth paragraph, unless the
element is expressly recited using the phrase "means for."
CLAIMS

What is claimed is:

1. An apparatus for distracting first and second adjacent vertebrae,
   comprising:
   an expandable implant configured to be inserted in a collapsed configuration
   within a facet joint bounded by the first and second vertebrae;
   wherein the expandable implant is configured to expand within the facet joint
   to increase a foraminal dimension associated with the first and second adjacent
   vertebrae.

2. An apparatus as recited in claim 1, wherein the expandable implant is
   configured to be installed in a facet joint located between at least one cervical
   vertebra.

3. An apparatus as recited in claim 1:
   wherein the facet joint comprises opposing articulating surfaces; and
   wherein the expandable implant is configured to engage the articulating
   surfaces to increase the distance between the articulating surfaces;
   said distance correlating to said foraminal dimension.

4. An apparatus as recited in claim 3, wherein the expandable implant
   comprises an inflatable balloon;
   said balloon configured to be filled with an inflation medium to distribute a
   compressive load on the articulating surfaces.

5. An apparatus as recited in claim 3:
   wherein the facet joint comprises a joint capsule that extends beyond the
   margin of the articulating surfaces; and
   wherein the expandable implant is configured to be delivered into the facet
   joint through an access hole created in the joint capsule.
6. An apparatus as recited in claim 5, wherein the expandable implant, in its expanded configuration, is larger than the access hole such that the expandable implant is retained in the facet joint once expanded.

7. An apparatus as recited in claim 6, wherein the expandable implant is configured to plug the access hole once expanded.

8. An apparatus as recited in claim 7, wherein the expandable implant is configured to occupy a substantial portion of the depth of the facet joint once expanded.

9. An apparatus as recited in claim 3, wherein the expandable implant is configured to dynamically stabilize the facet joint.

10. An apparatus as recited in claim 9, wherein the expandable implant is configured to increase and maintain a minimum distance between the articulating surfaces, while allowing motion of the first vertebrae with respect to the second vertebrae.

11. An apparatus as recited in claim 1: wherein the expandable implant is configured to attach to a distal tip of a catheter to facilitate installation into the facet joint; said catheter configured to transport said inflation medium into said expandable implant; and wherein the expandable implant is configured to detach from the catheter once the implant is expanded in the facet joint.

12. A method of minimally invasively distracting first and second adjacent vertebrae, comprising: inserting an expandable implant into a facet joint bounded by the first and
second vertebrae;
  wherein the to be expandable implant is delivered to the facet joint in a collapsed configuration;
  and expanding the expandable implant within the facet joint to increase a foraminal dimension associated with the first and second vertebrae.

13. A method as recited in claim 12, wherein inserting an expandable implant comprises installing the expandable implant in a facet joint located between at least one cervical vertebra.

14. A method as recited in claim 13:
  wherein the facet joint comprises opposing articulating surfaces; and
  wherein expanding the expandable implant comprises engaging the articulating surfaces to increase the distance between the articulating surfaces;
  said distance correlating to said foraminal dimension.

15. A method as recited in claim 13:
  wherein the facet joint comprises a joint capsule that extends beyond the margin of the articulating surfaces;
  wherein inserting an expandable implant comprises:
    creating an access hole through the joint capsule; and
    inserting the expandable implant in a collapsed configuration through the access hole and into the facet joint.

16. A method as recited in claim 15, wherein the access hole is created with an introducer needle.

17. A method as recited in claim 15, wherein the expandable implant, in its expanded configuration, is larger than the access hole such that the expandable implant is retained in the facet joint once expanded.
18. A method as recited in claim 15, further comprising:
plugging the access hole as a result of the expanded implant.

19. A method as recited in claim 14, wherein expanding the expandable implant comprises:
filling an inflatable balloon with an inflation medium;
engaging the articulating surfaces the expandable implant; and
imparting a compressive load on the articulating surfaces to distract the first vertebra from the second vertebra.

20. A method as recited in claim 15,
wherein inserting an expandable implant comprises:
feeding a catheter through the access hole and into the facet joint;
wherein the expandable implant is attached to a distal tip of a catheter;

21. A method as recited in claim 20, wherein expanding the expandable implant comprises:
transporting an inflation medium into said expandable implant via the catheter;
and
inflating the expandable implant with the inflation medium;
wherein the expandable implant is configured to detach from the catheter once the implant is expanded in the facet joint.

22. A method as recited in claim 14, further comprising:
dynamically stabilizing the facet joint as a result of the expanded implant being disposed between the articulating surfaces of the facet joint.

23. A method as recited in claim 14, further comprising:
maintaining said distance between the articulating surfaces while allowing motion of the first vertebrae with respect to the second vertebrae.
24. A method as recited in claim 21, wherein the extent of inflation of the expandable member is determined via patient feedback while the expandable member is being inflated.

25. A system for distracting a first vertebra from a second adjacent vertebra, comprising:
   - an expandable implant; and
   - a catheter;
   wherein the expandable implant is configured to be detachably installed in a collapsed configuration on the distal tip of the catheter;
   wherein the expandable implant and catheter are configured to be inserted into a facet joint bounded by the first and second vertebrae;
   wherein the expandable implant is configured to expand within the facet joint to increase a neural foraminal height associated with the first and second vertebrae.

26. A system recited in claim 25, wherein the expandable implant is configured to be installed in a facet joint located between at least one cervical vertebra.

27. A system as recited in claim 25, wherein the facet joint comprises a joint capsule that extends beyond the margin of the articulating surfaces; and wherein the expandable implant is configured to be delivered into the facet joint through an access hole created in the joint capsule.

28. A system as recited in claim 27, further comprising:
   - an introducer needle configured to create said access hole.

29. A system as recited in claim 26:
   wherein the facet joint comprises opposing articulating surfaces; and wherein the expandable implant is configured to engage the articulating
surfaces to increase the distance between the articulating surfaces;
said distance correlating to said foraminal height.

30. A system as recited in claim 29, wherein the expandable implant
comprises an inflatable balloon;
said balloon configured to be filled with an inflation medium via the catheter to
distribute a compressive load on the articulating surfaces.

31. A system as recited in claim 30, wherein the expandable implant is
configured to detach from the catheter once the implant is expanded.

32. A system as recited in claim 27, wherein the expandable implant, in its expanded configuration, is larger than the access hole such that the expandable implant is retained in the facet joint once expanded.

33. A system as recited in claim 32, wherein the expandable implant is configured to plug the access hole once expanded.

34. A system as recited in claim 25, wherein the expandable implant is configured to maintain said increased foraminal height, while allowing motion of the first vertebrae with respect to the second vertebrae.
