(54) Titre : DETENDEUR DE PRESSION PLURI-ETAGE COMPACT
(54) Title: COMPACT MULTI-STAGE PRESSURE REDUCING VALVE

(57) **Abrégé/Abstract:**

A flow control and pressure reducing valve has a valve body with an inlet chamber and outlet chamber separated by a partition plate. A plurality of passages are formed in the valve body spaced circumferentially around the partition plate and have an inlet portion opening into the inlet chamber and an outlet portion opening into the outlet chamber. Elastomeric flow control means are positioned in the passages and are responsive to pressurized fluid introduced therein to control flow of fluid through the passages around the partition plate. The valve configuration allows the mounting of inlet and outlet gates within the inlet and outlet chambers to eliminate the need for separate gate valves. An auxiliary flow passage may be provided through the partition plate and flow controlled therethrough to increase the flow capacity of the valve yet still provide full flow and pressure control. Air inlet and relief valves may also be provided as an integral part of the valve.

ABSTRACT OF THE DISCLOSURE

A flow control and pressure reducing valve has a valve body with an inlet chamber and outlet chamber separated by a partition plate. A plurality of passages are formed in the valve body spaced circumferentially around the partition plate and have an inlet portion opening into the inlet chamber and an outlet portion opening into the outlet chamber. Elastomeric flow control means are positioned in the passages and are responsive to pressurized fluid introduced therein to control flow of fluid through the passages around the partition plate. The valve configuration allows the mounting of inlet and outlet gates within the inlet and outlet chambers to eliminate the need for separate gate valves. An auxiliary flow passage may be provided through the partition plate and flow controlled therethrough to increase the flow capacity of the valve yet still provide full flow and pressure control. Air inlet and relief valves may also be provided as an integral part of the valve.

COMPACT MULTI-STAGE PRESSURE REDUCING VALVE

5

S P E C I F I C A T I O NBackground of the Invention

10 Field: The invention is in the field of flow control and pressure relief valves for controlling the flow of fluid through a pipe line.

15 State of the Art: Various types of valves are currently in use to control the flow of fluids through a pipe line and to reduce the pressure of a fluid in a pipe line. Where pressure reducing valves are used, it is generally necessary to provide a separate gate valve upstream from the pressure reducing valve and a separate gate valve downstream from the pressuring reducing valve. Further, the pressure reducing valve itself generally has a significantly smaller inlet and outlet diameter than the diameter of the pipe line in which it is installed so that size reducers and other fittings are required to install such valves in the pipe line. When the pressure reducing valves fail, they fail completely, thus allowing flow of fluid through the valve at full pressure which can result in considerable damage to pipes or other items downstream of the valve which are suppose to be protected from such high pressures by the pressure reducing valve.

20 A common type of pressure reducing valve in use today has a passage that extends from the inlet of the valve, through a valve seat, to the outlet of the valve. A valve disc is positioned against the valve seat to block the flow passage through the valve when it is desired to stop flow of fluid therethrough, and is adjustably positioned a distance from the valve seat to open the passage a selected amount to allow controlled flow through the valve and controlled pressure reduction in the fluid flowing through the valve from inlet to outlet. This type of valve has the disadvantages of relatively large size and weight for a given flow volume and a number of mechanical parts that are subject to wear. Cla-Val Co. of Newport Beach, California manufactures a valve of this type which has four separate valve seats with associated separate valve discs spaced about a valve body.

25

30

35

2080815

5 Rather than using a valve seat and associated valve disc, some valves, such as those manufactured by the Roll Seal Valve Company, Inc. of Temecula, California, use an elastomeric liner to control fluid flow. These valves include a valve seat extending circumferentially about the inside of the valve body with the liner extending about an inner portion of the valve body and inflatable so that when filled with a pressurized fluid, will press against the valve seat to close the flow passage through the valve. By controlling the pressure of the fluid in the liner, flow through the valve is controlled. The problem with this type of valve is that the liner can be ruptured or dislodged, thereby causing the valve to fail so pressure is no longer controlled downstream of the valve. Another problem is that if the liner ruptures or becomes dislodged, the valve must be removed in order to replace the liner.

15 Summary of the Invention

20 According to the invention, a flow control and pressure reducing valve includes a valve body, preferably cast as a single piece, having an inlet chamber and an outlet chamber. Partition means, preferably integrally cast with the valve body, separates the inlet and outlet chambers. In one embodiment, the valve body is cylindrical in form with a central bore which is divided into the inlet chamber and outlet chamber by the partition means which preferably takes the form of a wall or plate extending perpendicularly to the axis of the central bore. In another embodiment, the valve body includes a lower valve body adapted to be connected to upstream and downstream pipes with an upper body including the partition means extending perpendicularly to the lower body. In the first embodiment, flow of fluid through the valve is generally in the same overall direction while in the second embodiment the direction of the flow of fluid is changed as the fluid enters the upper valve body and reversed as it flows back into the lower body.

30 A plurality of passages are formed in the valve body spaced circumferentially around the partition means and extending through the valve body around the partition means from the inlet chamber to the outlet chamber. Each passage has an inlet portion opening into the inlet chamber adjacent one face of the partition means and an outlet portion opening into the outlet chamber adjacent the other face of the partition means. In addition to extending between the inlet and outlet chambers, the passages

35

2080815

preferably also extend radially through the valve body to form an outside passage access opening on the outside surface of the valve body. The passages serve as receptacles for flow control means and preferably taper inwardly toward the inside of the valve body to take the form of truncated cones.

Elastomeric flow control means are positioned in the passages and are responsive to pressurized fluid introduced into the flow control means to controllably restrict the passages. When operated to close a passage, the flow control means extends across the passage inlet and passage outlet portions and seats against the portion of the partition means between the inlet and outlet portions to thereby block the passage to prevent flow of fluid therethrough. In other positions, the flow control means is operated so that it is displaced from the portion of the partition means between the passage inlet and passage outlet portions to allow flow of fluid around the partition means. The distance the control means is displaced from the partition means determines the size of the flow passage and the amount of fluid allowed to flow around the partition means. The flow control means preferably take the form of elastomeric bladders configured to be snugly received in the passages. One side of the bladder extends across the passage inlet and passage outlet portions as described above, while the other end of the bladder extends across the outside access opening of the passage. The bladder is held in place by a cover extending across such outside opening. This cover may advantageously take the form of a ring extending about the valve body. While each passage may receive a separate bladder, it is preferred that each bladder be configured to fit into several adjacent passages. Each bladder, whether configured to fit into individual passages or into several adjacent passages, has a means for supplying pressurized fluid thereto which generally will take the form of a connector for connection to a source of pressurized fluid. Pressurized fluid in the bladder controls operation of the bladder to control flow through the valve. The actual control of the valve may be accomplished with various well known valve control techniques.

In some cases it may be desirable to reinforce the portion of the bladder or other elastomeric flow control means that extends across the inlet or outlet openings of the passages to either strengthen such portions to prevent bulging or deformation under high pressure conditions, or to increase the sealing properties of the flow control means across the inlet and outlet

2080815

openings of the passages. In such instances, metal or other rigid or semi-rigid plates may be embedded in the desired portions of the elastomeric flow control means. Various other types of reinforcing for the elastomeric flow control means may also be used such as wire or fiber mats or screens.

5 In many cases it will be desirable to include gates within the valve to eliminate the need for separate gate valves located upstream and downstream from the pressure reducing valve. These gates can be operated to stop flow of fluid through the valve in case of a malfunction of the flow control means or its control system. When gates are to be used with the
10 valve, gate mounting means is provided in the inlet chamber for mounting an inlet or upstream gate and/or in the outlet chamber for mounting an outlet or downstream gate. The gate mounting means may take the form of gate mounting shafts secured to the partition means and extending outwardly therefrom into both the inlet chamber and outlet chamber along the axis of
15 the central bore of the valve body. In one embodiment of the invention, the gate mounting shafts are threaded and receive thereon mating, internally threaded mounting hubs of the gates. Means are then provided for rotating the gates to cause them to move along the gate mounting shafts either toward a closed position when the gate is adjacent the partition means or an
20 open position when the gate is spaced from the partition means to allow flow of fluid between the gate and partition means. The gates may be driven individually through the direct engagement of a worm-rod with a handle at its end, or they may be driven simultaneously by means of a drive assembly including a worm-rod with handle at its end which drives a pinion and tie rod.
25 The pinion drives one of the gates while the tie rod drives a second pinion which drives the other gate. For automatic operation of the gates, the gates may be driven by motors actuated by pressure sensors or various other controls.

30 Rather than mounting the gates for rotation on a shaft in the inlet and/or outlet chambers, the gates can be mounted for sliding movement in such chamber and the sliding movement may be controlled hydraulically or mechanically. Further, in some embodiments of the valve, the gates may take the form of elastomeric gate means operated by providing pressurized fluid to the elastomeric gate means to cause it to block flow of fluid.

35 An important advantage of the valve of the invention is that the elastomeric flow control means of the valve may be easily removed and

5 replaced without having to remove the valve from the line. This is accomplished with flow through the valve stopped by either the internal gates of the valve, or by other means if the valve is not provided with internal gates, by merely sliding the cover from over the outside access openings of the passages, removing the flow control means to be replaced, and inserting the new flow control means. The cover is then replaced to hold the flow control means in place. Further, since a plurality of separate flow control means are generally used, if one fails, it only effects a portion of the valve so the valve can still function and does not fail completely. The valve of the invention can incorporate a pressure sensor in communication with the passages to sense if a flow control means fails and produce a warning signal to indicate such failure.

10 The construction of some embodiments of the valves of the invention allow for incorporation of an air relief means to release air when the lines to which the valve is connected are being filled with fluid, and air inlet means to remove the vacuum which tends to form in the line downstream of the valve when the valve or other valves in the system are closed to stop flow of fluid. This eliminates the need for separate installation of such means.

15 In one aspect, the invention resides in a flow control and pressure reducing valve, comprising:

a valve body having an inlet chamber and an outlet chamber therein;

a partition means within said valve body separating the inlet chamber and the outlet chamber;

20 a plurality of passage means extending through the valve body from the inlet chamber to the outlet chamber, said passage means each having an inlet opening at one end whereby the passage opens into the inlet chamber and an outlet opening at the other end whereby the passage opens into the outlet chamber;

25 a first cylindrical inlet chamber sealing portion of a first diameter;

30 a second cylindrical inlet chamber sealing portion of a second diameter spaced axially along the inlet chamber from the first cylindrical inlet chamber sealing portion;

35

gate means, said gate means having a gate means first diameter portion sealingly and slidingly received in said first cylindrical inlet chamber sealing portion and a gate means second diameter portion sealingly and slidingly received in said second cylindrical inlet chamber sealing portion, the relative lengths of the gate means first diameter portion, the gate means second diameter portion, the first cylindrical inlet chamber sealing portion, and the second cylindrical inlet chamber sealing portion being such to allow the gate to move between a closed position wherein one end of the gate is adjacent the partition means and blocks flow through the inlet chamber to the inlet openings of the passages and an open position wherein the one end of the gate is moved away from the partition means to allow flow through the inlet chamber and into the inlet openings of the passages, and so that a sealed control chamber is formed between the gate means and the inlet chamber, said control chamber varying in volume as said gate means slides within the inlet chamber; and

means for controlling flow of a control fluid into and out of said control chamber to control movement of the gate means within the inlet chamber.

In another aspect the invention provides a flow control and pressure reducing valve, comprising:

a valve body having an inlet chamber and an outlet chamber therein;

a partition means within said valve body separating the inlet chamber and outlet chamber;

a plurality of passage means extending through the valve body from the inlet chamber to the outlet chamber; gate means;

threaded shaft means rotatably mounting the gate means at least partially in a chamber of the valve for limited travel in the axial direction along the shaft means between a closed position wherein the gate means substantially blocks flow of fluid through the chamber and an open position wherein the outlet gate means does not

substantially block flow of fluid through the chamber; circumferentially spaced teeth extending radially outwardly from the gate means and extending longitudinally along the gate means; and

5 means engaging the teeth for causing the gate means to rotate on the threaded shaft means for controllably moving the gate means within the chamber to positions between its open and closed positions.

30 Detailed Description of the Illustrated Embodiment

As shown in Figs. 1-4, a pressure reducing valve of the invention includes a cylindrical valve body 5 having a central bore therein divided into an inlet chamber 6 and an outlet chamber 7 by a partition plate 5a which extends across the central bore perpendicularly to the bore's longitudinal axis. The partition plate is preferably formed integrally with the valve body
35 such as by casting.

2080815

5 A plurality of flow control means receptacles 10 are formed in valve
body 5 and are spaced circumferentially around the partition plate 5a. Each
of the receptacles 10 forms a passage extending between inlet chamber 6 and
outlet chamber 7 around partition plate 5a. Each passage has an inlet portion
10a, Fig. 3, and an outlet portion 10b. The partition plate 5a separates the
inlet portion 10a from the outlet portion 10b of each passage. Preferably,
the receptacles and partition plate are located so that the inlet and outlet
portion of each passage are symmetrically located adjacent opposite faces of
the partition plate 5a and are of equal size, as shown. The receptacles 10
10 extend radially through the valve body 5 to an outside passage access opening
10c, Figs. 3 and 4, on the outside surface of valve body 5. The receptacles
are shown as tapering inwardly toward the inside of the valve so that each of
the receptacles 10 take the form of a truncated cone, see particularly Fig. 3.

15 Elastomeric flow control means are shaped to fit into and be snugly
received within the receptacles 10. These flow control means may
conveniently take the form of elastomeric bladders 25, Figs. 1-3. Fig 4 does
not show the bladders. The portions of the bladder which fit into the
passages 10 are shaped similarly to such passages as shown in Figs. 1-3. Fig.
7, a transverse section through a bladder and receptacle, further illustrates
20 the shape of the receptacles and received bladders therein. While a separate
bladder control means could be provided for each receptacle, it is preferred
that the bladder be formed to fit into several adjacent receptacles as shown
in Figs. 1 and 4 where one bladder 25 is shown as formed to fit into seven
adjacent receptacles and a second bladder 25 is shown as formed to fit into
25 the remaining eight adjacent receptacles. In such case each bladder is
elongate with a plurality of bladder extensions on one side thereof with each
extension configured to fit into a receptacle. While a single common bladder
could be formed to fit into all receptacles of the valve, it is preferred that
the receptacles be divided into at least two sets with two independent
30 bladders as shown. Sides 25b of the bladders are configured so that they can
assume a position as shown in Figs. 2 and 3 wherein they extend across
passage inlet portion 10a and passage outlet portion 10b and seat against the
portion of partition plate 5a therebetween to prevent communication
between inlet 10a and outlet 10b. The bladder wall 25b, however, can be
35 deformed to move away from partition 5a to allow communication between
the inlet and outlet as shown by broken lines in Fig. 2.

2080815

5 The bladders 25 are held in the receptacles 10 by cover ring 13, which is secured in position over the receptacles by means of flange 56 along one side thereof which mates with flange 61 extending from valve body 5. Bolts, or other fasteners, extending through mating holes 60 in the two flanges may be used to secure the cover ring 13 to the valve body. With such construction, cover ring 13 can be easily released and slid away from flange 61 to either partially or completely expose the passage access openings 10c of the control means receptacles 10 to allow easy access to the receptacles for replacement. A gasket 40 between the abutting flanges and an "O"-ring 39 positioned in valve body 5 to bear against the inside edge surface of the cover ring opposite the edge with the flange, seal the cover ring against leakage when secured in place over the receptacles. If desired, the outside of the valve body could be tapered to facilitate movement of cover ring 13.

10 Each of the bladders 25 is provided with a connector 26, Fig. 1, communicating with the inside of the bladder and adapted to be connected to a source of pressurized fluid. Connectors 26 extend through openings 74 provided in cover ring 13. Connectors 26 are shorter than the depth of the receptacles 10 so that a bladder 25 may be easily installed by positioning it in the appropriate receptacle and depressing the connector into a receptacle thereby deforming the bladder to which it is attached and maneuvering the connector under a portion of cover ring 13 to the appropriate receiving opening 74. The resilient nature of the bladder will generally push the connector through hole 74. The connector can then be sealingly secured to ring 13 by a nut 27 threaded onto the outside of the connector, or by a threaded hose connector which connects the bladder to a source of pressurized fluid. In either case, the base of the connector where attached to the bladder is covered with the elastomeric material of bladder 25 so hole 74 is sealed as the base of the connector is pulled against ring 13. Conduits 18 are attached to connectors 26 and extend to a source of pressurized fluid for pressurizing bladders 25.

20 The structure described so far provides a basic flow control and pressure regulating valve of the invention which is shown in this basic form in Fig. 3. The valve may be attached, as shown in Fig. 2, to the flange 8a of an inlet pipe or size reducer 8 by means of bolts threaded into mounting holes 14 and to flange 9a of outlet pipe or size reducer 9 by means of bolts 11, Fig. 3, passing from the flow control means receptacles 10 through openings 11a,

2080815

Fig. 2, in valve body 5 and flange 9a. Either of the securement methods described can be used on either side of the valve, or other means could be used to secure the valve to mating pipes.

5 Passage 67, Figs. 2 and 3, extends through valve body 5 to communicate with valve inlet chamber 6 and provide fluid at the inlet pressure through conduit 16, Fig. 2, to a needle valve 17. After passage through the needle valve, the fluid is provided to the interior of the bladder through conduit 18 and also to a control or pilot valve 20. From the pilot or control valve the fluid is connected through conduit 21 to passage 68 which extends through
10 valve body 5 to communicate with outlet chamber 7. This is a standard pressure control system for pressure regulating valves and supplies pressurized fluid to the bladder to operate the valve. By adjustment of the control valve 20, any pressure between the inlet and outlet pressures of the valve of the invention can be maintained within the bladder 25. The system
15 works in well known manner to adjust the pressure in bladder 25 so that the valve of the invention will maintain a constant output pressure regardless of the inlet pressure. Presently, it is anticipated that a separate control system connected to passages 67 and 68 should be used for each separate bladder used in the valve. Various other valve control systems can be used to supply
20 pressurized fluid to the bladders 25, and, if independent control is desired, the bladders can be connected to a source of controlled pressurized fluid independent from the fluid being controlled by the valve.

In operation of the valve, when the pressure inside bladder 25 is substantially the same as the pressure of the fluid entering the valve and
25 acting against walls 25b of bladder 25, the pressure inside bladder 25 is sufficient to hold bladder walls 25b against the partition plate 5a, as shown in solid lines in Fig. 2, thereby holding the valve in closed condition with walls 25b blocking flow of fluid between passage inlet portions 10a and passage outlet portions 10b. When the pressure of the fluid inside bladder 25 is
30 reduced, bladder walls 25b are displaced from their seats against partition plate 5a, such as shown by broken lines in Fig. 2, thereby connecting passage inlet portions 10a and passage outlet portions 10b to allow flow of fluid through the valve around partition plate 5a. By adjusting the pressure supplied to a bladder 25, the displacement of bladder walls 25b and thus the
35 amount of flow allowed around partition plate 5a can be accurately controlled.

2080815

Because a plurality of receptacles are provided in the valve and because separate bladders are used in connection with separate groups of these receptacles, if one of the bladders should rupture, the remaining one or more bladders will continue to operate to control pressure and flow through the valve. Thus, if two bladders are used, and one of the bladders ruptures, full flow may occur through the passages with the ruptured bladder and complete stoppage of flow and reduction to zero pressure of the output cannot occur. However, the remaining unruptured bladder will continue to operate and the valve will be effective to control the flow and pressure drop through the valve through an upper portion of the normal control range of the valve. The more independent bladders that are used, the less effect the rupture of one of the bladders will have on the operation of the valve, i.e., the larger will be the portion of the normal control range that remains effective. Thus, the number of independent bladders used can be chosen based upon the least allowable pressure drop between inlet and outlet of the valve, i.e., the maximum pressure allowed at the outlet of the valve. This is a significant advantage of the valve of the invention.

In order to provide an indication of a bladder rupture, a conduit 26b may be provided through an opening 75 in cover ring 13 located at an end of a bladder as shown in Fig. 1. A separate conduit 26b will be provided for each separate bladder used. Each conduit 26b is secured to cover ring 13 by nut 26c. Openings 75 are sealed by gaskets 74a. In normal operation of the valve, the bladder 25 covers and seals the opening to conduit 26b as shown in Fig. 1. If a bladder ruptures, the turbulence of the water flowing through the receptacles with the ruptured bladder is sufficient to dislodge the end of the bladder to the extent that fluid at substantially the inlet pressure enters conduit 26b. Conduit 26b is connected to a pressure sensor, which, upon sensing pressure in the conduit will generate a signal which is sent to an indicator means to activate the indicator means to provide an alarm or other indication of a ruptured bladder.

Another significant advantage of the valve of the current invention is that a bladder can be replaced without removing the valve from the line. The flow of fluid through the valve must be stopped, such as by a separate gate valve upstream of the valve of the invention. Then cover ring 13 is slid away from flange 56 to at least partially uncover the receptacles 10. The resilient bladders can then easily be removed and replaced as desired. With the

2080815

embodiment of Figs. 1-4, conduit 16 to needle valve 17 will have to be disconnected to allow cover ring 13 to be slid from its position over the receptacles. Since only a partial uncovering of the receptacles is necessary, it will generally not be necessary to remove the conduits 26b or the conduits 26 from cover ring 13 for the bladders not being replaced.

It should be realized that the number of receptacles 10 provided in the valve, the size of such receptacles, and the wall thickness between receptacles will vary with the size of the valve and the desired flow capacity of the valve. Also, the particular configuration of the passages can vary with the preferred configuration being the truncated cones illustrated, wherein, if the cones were extended, the apex of each cone would lie on the central longitudinal axis of the valve body. Alternatively, the cones could be such that the apex of each cone extends beyond the center of the valve body so that the apexes lie on a circle with the center of the valve body the center of the circle. Several alternative preferred configurations for the passages and bladders are shown in Figs. 8 to 10. Fig. 8 shows an alternate cone configuration while Figs. 9 and 10 show alternate pyramid configurations. It is preferred that the side walls of the receptacles 10 slope inwardly, giving the truncated cone configuration illustrated or an alternate pyramid configuration, so that the pressurized fluid in the bladders against bladder walls 25a will work against the side walls of the receptacles and the bladders will remain seated against the side walls to prevent leakage of the fluid in the valve around and behind the bladders. In addition, the particular configuration of the portions of the partition plate 5a extending over the passages or receptacles 10 between the passage inlet and outlet portions may vary as may the configuration of bladder walls 25b which mate against such partition plate portions. It is preferred that the partition plate portions be semicircular as shown and that the bladder walls 25b be normally similarly semicircular or partially spherical, as shown, to provide good sealing characteristics. However, the portions of the partition plate over the passages could be semicircular away from the passages, oppositely to the configuration shown, so the partially spherically walls 25b would normally extend outwardly from bladder 25 to close the passages. This configuration could increase the flow capacity of the valve. Various other configurations could also be used.

2080815

Where the valve of the invention is to be used to reduce extremely high pressures, it may be desirable to include gates in the valve to help control the flow and pressure drop through the valve. With gates included in the valve, the valve becomes a two or three step reducing valve depending upon whether one or two gates are used. To provide gates in the valve of Figs. 1-4, two shafts 23, Fig. 2, are secured to partition plate 5a with one shaft extending along the central longitudinal axis of the bore of the valve into the inlet chamber and the other shaft extending along the central longitudinal axis of the bore into the outlet chamber. With the particular embodiment shown in Fig. 2, the shafts 23 are threaded to receive thereon the threaded mounting hubs 49 of cylindrical gates 24. Arm rods 28, Figs. 2 and 4, extend across the axis of the gate and secure the gate mounting hubs 49 to the cylindrical gate bodies 24. End flanges 24a and 24b are provided at opposite ends of the cylindrical gate bodies 24 and are sized to closely fit into either the valve inlet chamber 6 or valve outlet chamber 7, as appropriate. The arms, shaft, cylindrical gate body and flanges may be of single piece construction or may be built up from separate components. The outside circumference of each gate body 24 between the flanges is configured to provide longitudinally extending teeth 42 which engage worm gears 21 of drive rods 20 which extend through packing glands 82 and retaining nut 83 in valve body 5. Wheel handles 3 on the ends of drive rods 20 allow the drive rods to be easily turned to cause rotation of the gates on shafts 23. Rotation of the gates cause them to move longitudinally along shaft 23 toward or away from partition plate 5a, the direction of movement depending upon the direction of rotation of the shafts. With the embodiment of Figs. 1-4, separate drive shafts are provided for each of the gates so each gate can be moved independently. Thus, gate 24 in inlet chamber 6 can be positioned to provide a controlled flow passage between the flange 24a and the partition plate while the gate 24 in outlet chamber 7 can be positioned to provide a controlled flow passage between its flange 24a and the partition plate. These passages may be set to provide a maximum flow and minimum pressure restriction while the bladder flow control means 25 provide flow and pressure regulation for the valve.

It is preferred that the threads 23b on shafts 23 be discontinuous, such as by having a channel 23a cut longitudinally through the threads, Figs. 11 and 12, and that the gate mounting hubs 49 have holes 49a therethrough

2080815

periodically along their length. This allows any deposits which build up on the threads of the shafts to be removed from the shafts and exuded through the holes 49a.

5 No seals are used with the gates shown in Fig. 2 so that with the gates in closed position shown in Fig. 2, there is still a small clearance between the gate body 24 and the partition plate 5a so some flow of fluid therebetween can occur. Thus, in order to replace a bladder 25, it is still necessary to shut off flow to the valve with a separate gate valve upstream of the illustrated valve.

10 As described above, with the valve of Figs. 1-4, in order to replace a bladder, it is necessary to shut off the flow of fluid through the valve by use of an additional gate valve upstream of the valve of the invention. In some instances this is not a problem, but in many instances, it would be advantageous to eliminate the need for the separate gate valves which are
15 generally required. As described above, the construction of the valve of the invention advantageously allows gates to be easily provided within the valve itself. These gates may be configured to include seals to thereby actually block flow through the valve when closed so that additional gate valves upstream or downstream of the valve of the invention are not needed.

20 Figs. 5 and 6 show an embodiment of a valve of the invention wherein the gates are provided with seals so completely stop flow through the valve when closed. Further, the valve has been modified so that the gates are moved simultaneously with a single gate control and the passage communicating with the inlet chamber of the valve has been modified so the
25 conduit to the needle valve does not have to be removed in order to slide the cover ring from over the passage access openings.

As shown in Figs. 5 and 6, a valve body 5d has a partition plate 5a and a plurality of passages 10 as in the embodiment of Figs. 1-4. However, the embodiment of Figs. 5 and 6 has an enlarged wall area 78, Fig. 6, between
30 two of the passages 10 to provide space for a conduit 79 which extends from opening 91 connecting with valve inlet chamber 6 to an outlet 79b on the opposite side of the valve. This conduit 79 takes the place of conduit 67 of the embodiment of Figs. 1-4 and moves the connection of conduit 16 to the opposite side of the valve so it does not interfere with the movement of cover
35 ring 13.

2080815

Partition plate 5a has a threaded shaft 23d, Fig. 5, extending into inlet chamber 6 and threaded shaft 23e extending into outlet chamber 7. Each of these shafts has an enlarged threaded portion 23f adjacent the partition plate 5a to receive thereon a seal holding plate 95 with central, threaded mounting hub 95a. About the circumference of each plate 95 is a cupped rim 95c which holds a gasket 37. Plates 95 are provided with radial ridges 95b to make an acoustical, knurled surface.

Gate 24d is mounted for rotation on shaft 23d and identical gate 24e is mounted for rotation on shaft 23e. Gates 24d and 24e are tapered so that the central flow passage through the gates is reduced in size toward the partition plate. Each gate has longitudinal teeth 42a about its outer circumference to mate with pinions 87. Pinions 87 are secured to shaft 98 so that they rotate together. A worm 21a, Fig. 6, on drive rod 20a passing through packing glands 82 and retainer nut 83 engages one of the pinions 87. Rotation of drive rod 20a, by means of wheel handle 3, causes the pinion 87 with which it is engaged and shaft 98 to rotate, thus also rotating the other pinion 87 mounted on shaft 98. Both gates 24d and 24e are thus rotated simultaneously.

When gates 24d and 24e are adjacent to partition plate 5a, as shown in Fig. 5, the inside edge of the gate contacts sealing gasket 37 to completely block all flow of fluid between the gates and the partition plate. A sealing gasket 47 in body groove 48 provides a seal about the outside of respective gates 24d and 24e to block any flow of fluid about the outside of the gates.

The inside surfaces of gates 24d and 24e are provided with a plurality of holes 101. These holes are provided to reduce the weight of the gates and also, importantly, to reduce the noise generated by flow of fluid through the gates.

It will be realized that the diameter of the pipes or reducers to which the valve is attached does not have to be the same as the diameter of the inlet chamber of the valve. Thus, as shown in Fig. 5, the inlet to the valve has a diameter D2 while the pipe to which it is connected may have a larger diameter of D1.

Fig. 13 shows another embodiment of a valve of the invention having a hydraulically activated gate in the inlet chamber of the valve. The valve of Fig. 13 includes the cylindrical valve body 5 with partition plate 5a, as well as the plurality of passages extending from the inlet chamber to the outlet

2080815

chamber around the partition plate and the elastomeric flow control means as explained for the previous embodiments. A size reducer 150 is secured to the inlet end of the valve body by bolts 151, while a size reducer 152 is secured to the outlet end of the valve body by bolts 153.

5 A cylindrical gate 155 is sized to be snugly but slidingly received in the inner, reduced diameter portion 156 of reducer 150, as shown, with a gasket 157 mounted in reducer 150 to form a fluid tight seal between the reduced diameter portion 156 of the reducer and gate 155. Gate 155 has an enlarged flange 158 at its end toward partition plate 5a sized to be snugly but slidingly
10 received within the inlet chamber of valve body 5. The end of flange 158 toward partition plate 5a has a groove 159 therein within which is received a gasket 160. The opposite end of the flange forms a shoulder 161 which has a gasket 162 mounted thereon. A bolt fastener 163 may be provided to secure gaskets 160 and 162 in place. Gasket 162 forms a fluid tight seal between
15 gate 155 and valve body 5, to form a fluid tight space 164 between the outer surface of gate 155 and the inside surfaces of valve body 5 and reducer 150.

A connector 165 communicates with space 164 and extends through reducer 150. The connector is adapted to be connected to a source of pressurized fluid. Gasket 166 ensures a fluid tight seal.

20 In operation, the gate 155 of Fig. 13 can slide toward partition plate 5a to closed position as shown in Fig. 13, or can slide away from partition plate 5a to allow flow of fluid between flange 158 and partition plate 5a. Gasket 160 is provided with an annular groove 160a therein which communicates through groove 159 with the pressurized fluid in the inlet chamber so that the
25 fluid pressure will help press gasket 160 against partition plate 5a when the gate is in closed position to thereby ensure a fluid tight seal.

The forward edge of flange 158 is tapered in a smooth curve from the inside thereof as at 167. This provides an area upon which pressurized fluid in the inlet chamber acts in a direction to try to move the gate to an open
30 position.

Movement of gate 155 is controlled by pressurized fluid supplied to space 164. When pressurized fluid is supplied through connector 165 to space 164, it will counteract pressure acting on tapered face 167 and, if the pressure is greater than that acting on face 167, causes the gate to move to
35 its closed position shown. If the pressure in space 164 is less than that acting on face 167, the gate will move toward open position away from the partition plate 5a until the pressures are equalized.

2080815

Thus, by controlling the pressure of fluid supplied to space 164, movement of the gate is controlled. With such arrangement, gate 155 can act to control and relieve pressure surges that may occur in closing the gate.

5 While gate 155 is shown only in the inlet chamber, it could be provided in the outlet chamber rather than in the inlet chamber, or similar gates could be provided in both inlet and outlet chambers. Where gates are provided in both inlet and outlet chambers, one gate may be as shown in Fig. 13, while the other could be of differing configuration and operation, such as a gate as shown in the earlier Figures.

10 Fig. 14 shows a further embodiment of a valve of the invention which includes a butterfly valve and by-pass passage through the partition plate of the valve. Again, the valve of Fig. 14 includes a cylindrical valve body 5 with partition plate 5a, as well as the plurality of passages around the partition plate and electromeric flow control means. However, partition plate 5a has
15 an opening therethrough in which is positioned a cylindrical insert 175 which provides a by-pass channel or auxiliary passage through the partition plate of the valve. Insert 175 is provided as part of a reducer 176 which is secured to the input side of the valve such as by bolts 177. An integral, annular ring 178 is formed on the outer surface of insert 175 and is positioned to abut
20 partition plate 5a, as shown. This helps to block flow through the partition plate around the outside of insert 175. The end of insert 175 opposite reducer 176 is adapted to abut a reducer 179 secured to the outlet of valve body 5.

Insert 175 is perforated as shown by inlet holes 180 as it passes through the inlet chamber of valve body 5. This forms a screen or grate for fluid
25 entering the inlet of the valve from insert 175. Similarly, the end of insert 175 which passes through the outlet chamber of valve body 5, is also perforated as shown by outlet holes 181 so that water can flow into insert 175. A butterfly valve 182 is rotatably positioned in insert 175 between inlet holes 180 and outlet holes 181. Gate 182 is mounted for rotation on opposed
30 stub shafts 183 projecting toward the center of insert 175 by brackets 184 secured to gate 182 by bolts 185. A semicircular rack 186 is mounted on gate 182 so as to be engaged by pinion gear 187 mounted on shaft 188. The lower end of shaft 188 as shown in Fig. 14 is positioned between insert ears 189 and, when its upper end is positioned to receive the lower end of shaft 190 therein, abuts insert stop 191. This holds pinion gear 187 in engagement with rack
35 186. Insert ears 189 and stop 191 form a receiving slot for the bottom of

2080815

shaft 188. The slot is open at one end so that the shaft may be easily slid thereinto. With shaft 190 in place to hold the top of shaft 188, rack 186 acts as a fulcrum or support to keep the bottom of shaft 188 in the receiving slot. Shaft 190 and the receiving recess therefor in shaft 188 are keyed so that
5 rotation of shaft 190 causes rotation of shaft 188. With this arrangement, shaft 188 can be easily positioned and held in insert 175. Shaft 190 extends through seal 192 and insert 175, and through seal 193 and valve body 5, to outside the valve body. A spring 194 acting against a washer 195 holds seal 193 securely in place to prevent leakage along the shaft. A projection 179a
10 of reducer 179 extends over valve body 5 where shaft 190 extends from the body to catch an enlarged portion 190a of shaft 190 and hold it securely in position in valve body 5. In this way, shaft 188 is positioned in insert 175, and shaft 190 is inserted through the valve body 5, gasket 193, washer 195, spring 194, insert 175, and gasket 192 into the receiving recess of shaft 188.
15 Reducer 179 is then secured in position so that projection 179a secures the shaft in place.

With this arrangement, rotation of shaft 190 from outside valve body 5 causes rotation of the butterfly valve within insert 175. Thus, butterfly valve 182 can be opened or closed from outside the valve. During normal operation
20 of the valve, butterfly valve 182 will be in closed position as shown in Figs. 14 and 15 to prevent flow of fluid through insert 175 and force the fluid to flow through inlet holes 180 into the inlet chamber of valve body 5, and then to flow in a controlled manner as described above from the inlet chamber to the outlet chamber around partition plate 5a, such flow being controlled by
25 the flow control bladders, and then from the outlet chamber through outlet holes 181 back into insert 175 on the other side of butterfly valve 182.

Insert 175 includes support rod 200 extending from one side of insert 175 to the other across the center thereof near the end opposite reducer 176. A threaded shaft 201 extends from support rod 200 along the central axis of
30 insert 175 for mounting threaded outlet gate hub 202. Cylindrical outlet gate 203 is mounted on outlet gate hub 202 by means of support arms 204. Gate 203 is flanged at both ends with gaskets 205 mounted in the flanges. The outside circumference of gate 203 between the flanges is configured to provide longitudinally extending teeth 206 which engage a worm gear 207
35 secured to a drive rod 208 which is rotatable from outside the valve body. When drive rod 208 is rotated, worm gear 207 rotates and causes gate 203 to

2080815

rotate. As gate 203 rotates, hub 202 also rotates therewith and causes longitudinal movement of the gate along threaded rod 201. Thus, gate 203 can be moved between a closed position as shown in Fig. 14 wherein the gate blocks outlet holes 181 to thereby close the outlet of the valve, to an open position wherein the gate is longitudinally displaced along the axis of the valve away from the valve to completely uncover outlet holes 181 to allow unrestricted flow from the valve outlet chamber into the insert. As desired, gate 203 may be positioned anywhere between closed and completely open positions to partially restrict flow through outlet holes 181.

Outlet holes 181 are provided rather than merely a completely open space between insert 175 and reducer 179 to ensure that gasket 205 remains properly positioned in the flange of gate 203 that traverses the holes since the gaskets are open to the inside of the gate through passages 210 so are pressurized by the pressure of the fluid in the gate. This ensures a good seal when the gate is closed, but may tend to push the gaskets from the gate flange if there is nothing to tend to hold the gasket in place. The portion of insert 175 between outlet holes 181 function to hold the gasket in place.

An inlet gate 220, similar to outlet gate 203 is mounted in the inlet portion of reducer 176 and insert 175. For this purpose, a shaft support member 221 is positioned upstream of reducer 176 and secured between an upstream pipe, not shown, and reducer 176 such as by bolts 223. Shaft support member 221 includes support arm 224 having a threaded shaft 225 extending therefrom into the inlet portion of insert 175. Gate hub 226 is mounted on shaft 225 and gate 220 is secured to hub 226 by support arms 227. Gate 220 has end flanges with gaskets 228 therein for providing good seals at each end of the gate. As with gate 203, gaskets 228 are open on the inside through channels 229 to pressurized fluid in the inlet of the reducer.

The outside circumference of gate 220 is configured to provide longitudinally extending teeth 230 which engage worm gear 231 secured to drive rod 232. As with outlet gate 203, drive rod 232 extends through the valve body and may be rotated from outside the valve body to cause rotation of gate 220 and longitudinal movement of the gate along shaft 225.

Gate 220 is shown in an open position in Fig. 14 whereby gate 220 has traveled longitudinally toward axle support 221 in an upstream direction from the valve so as to expose inlet holes 180 to allow fluid to flow from the insert into the inlet chamber of the valve. From this open position, gate 220 can be

2080815

5 moved by rotating it so that it travels along shaft 225 to a closed position wherein it completely covers inlet holes 180. Reducer 176 and insert 175 at the inlet of the valve is shown having a length sufficient to contain gate 220 completely therein when in both open and closed conditions. Reducer 179 at the outlet of the valve is shown having a length sufficient to completely contain the outlet gate 203 only in its closed position. As gate 203 is opened, the downstream end thereof moves from inside reducer 179 into the downstream pipe or further reducer to mate with a larger downstream pipe connected thereto, not shown. This generally is not a problem, but reducer 10 179 could be lengthened if desired.

15 In normal operation of the valve of Fig. 14, butterfly valve 182 will be closed and both inlet gate 220 and outlet gate 203 will be open. Fluid will flow in the general direction of the arrows. Flow of fluid through the valve is controlled by the elastomeric bladders as previously described. If desired, either the inlet gate 220 or outlet gate 203, or both can be set to restrict flow to some extent. If replacement of one of the bladders of the valve is necessary and it is not desired to shut off flow through the valve, butterfly valve 182 may be opened to the extent necessary to allow desired flow at desired pressure through insert 175 around butterfly valve 182. Inlet and outlet gates 220 and 203 are closed to completely block flow of fluid through the inlet and outlet holes. In this configuration, bladders can be replaced or other repairs made to the valve, and flow continues through the valve, controlled by butterfly valve 182. This will give some pressure control, but does not provide the high degree of pressure control and regulation achieved by the valve of the invention. However, it will generally be satisfactory for short time periods. Further, since some flow through the valve takes place. The pressure against the gate seals is not as great so there is less chance of leakage. When repairs are complete, the gates are again opened and the butterfly valve closed.

30 If it is desired to completely stop flow of fluid through the valve, butterfly valve 182 can remain closed and gates 220 and 203 also closed.

35 If it is desired to supplement the flow of fluid through the valve, butterfly valve 182 can be opened to a desired degree to allow an uncontrolled base flow of fluid through the valve and additional flow may be controlled by the elastomeric bladders. Further, while the butterfly valve 182 has been shown mounted in an insert 175 which extends through the inlet

2080815

5 chamber, partition plate, and outlet chamber to facilitate blocking flow of fluid into the inlet chamber, if desired, the insert is not necessary and an auxiliary passage with valve, butterfly type or otherwise, could be provided if desired to supplement flow of fluid through the valve, or to allow flow through the auxiliary passage to clear debris that may enter and get stuck in the inlet chamber.

10 A further embodiment of a valve of the invention is shown in Figs. 16 and 17. A lower valve body 250 is connected through integral flanges 251 and 252 to upstream and downstream pipe flanges, only downstream pipe flange 253 being shown, such as by bolts 254. An upper valve body 255 extends at right angles to lower valve body 250 and houses an inlet chamber 256 and an outlet chamber 257, separated by partition plate 258. The inlet chamber 256 extends into lower valve body 250 to valve inlet opening 260. An outlet passage 261 formed by walls 262 extends from outlet chamber 257 to valve outlet opening 263. The outlet passage preferably extends concentrically through the inlet passage adjacent partition plate 258. A plurality of passages 265 extend from the inlet chamber to the outlet chamber around partition plate 258 and serve as receptacles for bladder 266, similarly to the valve of Figs. 1-4. Bladder 266 is held in place by cover ring 267 secured about upper valve body 255. O-rings 268 form a seal for cover ring 267. Pressurized fluid is supplied to the bladder 266 as previously described through connectors 268, Fig. 17, which communicate with the inside of bladder 266 and are adapted to be connected to a source of pressurized fluid as described. The pressurized fluid operates the bladder to control flow of fluid from the inlet chamber 256 to the outlet chamber 257 through passages 265 around partition plate 258 as has been explained for previous embodiments

25 As shown in Fig. 17, upper valve body 255 is configured to provide a total of six passages or receptacles 265 and the tapers of opposite walls of the receptacles are such that if extended, they would intersect before crossing the central axis of the upper valve body. This arrangement allows easy casting of the upper valve body. A single bladder 266 is shown in the valve of Fig. 17, each end being held in position by a connector 268, but several separate bladders could be used, if desired. The two connectors 268 communicating with the two ends of a common bladder allow for faster and more even pressure changes in the bladder and hold the bladder in place. The

2080815

two connectors will generally be connected through a tee connection to a single source of pressurized fluid.

5 In some instances, such as when the pressure handled by the valves are particularly great, the bladders may have a tendency to deform or balloon outwardly into the outlet chamber when pressurized to block flow of fluid. In such instances it may be desireably to reinforce the portion of the bladder extending across the inlet and outlet chambers. As shown in Figs. 16 and 17, this reinforcing may take the form of metal or other rigid or semi-rigid plates 270 embedded in the elastomeric material of the bladders. This reinforcing will resist ballooning or other deformation of the elastomeric flow control material where it crosses the inlet and outlet openings and, in such instances, will ensure a good seal against the partition plate. Further, if the taper of the receptacle walls are as shown in Fig. 17, the ends of the reinforcing plates will exert pressure against and seat against the receptacle walls to further prevent ballooning of the elastomeric material and to further seal the material against the receptacles to prevent possible leakage.

10 The reinforcing shown is merely an example of reinforcing that might be desireable under certain conditions and various reinforcing could be used. Further, the reinforcing plates shown might be split to provide one over the inlet opening and one over the outlet opening, or only one over the outlet opening. The reinforced elastomeric material may be used with any of the valves described or the non-reinforced material as shown in prior drawings may be used in the valve configuration of Figs. 16 and 17.

20 As shown in Fig. 16, outlet chamber 257 is closed at its end opposite outlet passage 261 by end wall 275 secured in the end of upper valve body 255 such as by bolts 276. A domed grate 277 is formed at the entrance of outlet passage 261 with openings 278 for flow of fluid from outlet chamber 257 into outlet passage 261. A vent passage 279 may be provided by tube 280 extending from the center of grate 277 through end wall 275. A standard air vent valve may be threaded onto the end 281 of tube 280 to allow air from the atmosphere to enter outlet passage 261 when desired, but for preventing flow of liquid from outlet passage 261 under normal valve operation and in case of attempted back flow of fluid. An air vent valve may be desireable to allow air to enter the downstream pipe through the valve when a vacuum is being created downstream of the valve through drainage of the pipe with the flow valve closed or through other operations. Further, when filling

2080815

downstream piping, particularly if done slowly, air pressure may build up in the pipe at the valve and it is desirable to release such air pressure. The air vent valves usually provides for such pressure release.

5 In many cases it will be desirable to provide further flow control through the valve by providing flow control or gate means in the outlet chamber. In the embodiment shown in Fig. 16, this additional flow control, which effectively forms a gate valve in the outlet chamber, takes the form of an elastomeric outlet gate means, shown as elastomeric outlet gate bladder 285. Bladder 285 is secured in place by sandwiching bladder flange 287
10 between the end of upper valve body 255 and end wall 275. This also seals the connection between upper valve body 255 and end wall 275 against leakage. A connector 286 which communicates with the interior of gate bladder 285 extends through end wall 275 and is adapted to be attached to a source of pressurized fluid. Gate bladder 285 operates similarly to bladder
15 266 in receptacle 265. When pressurized, the bladder is expanded to fill the outlet chamber and to cover and seal openings 278 through grate 277. Further, outlet bladder 285 will abut bladder 266 through at least a portion of the outlet chamber, and if bladder 286 is not reinforced, will counteract any tendency for it to balloon into the outlet chamber.

20 During flow of fluid through the valve, the pressure in gate bladder 285 is reduced and the pressure of the fluid flowing through receptacles 265 will displace the bladder toward the end wall 275 to open openings 278 to allow flow of fluid through grate 277. Actually, bladder 285 operates similarly to the bladders in the receptacles to control flow of fluid and, if desired,
25 openings could be provided through partition plate 258 and gate bladder 285 used to control flow of fluid through such openings. It is currently preferred to use gate bladder 285 as a flow control means additional to the flow control provided by bladder 266, but it would be possible to eliminate bladders 266, or even receptacles 265 if replaced by openings through partition plate 258, and
30 use gate bladder 285 as the flow control means. In such instance the outlet passage 261 becomes the outlet chamber, and the outlet chamber 257 becomes the receptacle for the elastomeric flow control means.

35 A passage 290 extending from one or more receptacle 265 is provided and is connected to a pressure sensor and indicator similarly as indicated in Fig. 1 to sense if a bladder 266 ruptures thereby allowing pressurized fluid into receptacles 265. Bladder 266 may be easily replaced, after stopping flow

2080815

upstream of the valve, by removing access cover 267. Outlet gate bladder 285 may be easily replaced by stopping flow through the valve with bladder 266 and removing end 275.

5 If debris collects in the inlet portion of the valve, it will collect in the lower portion of the lower valve body. In order to allow clean-out of any collected debris, a clean-out outlet 292 is provided which may be opened to allow pressurized fluid to flow therefrom for a short time to wash out any collected debris.

10 A passage 293 is provided into the inlet chamber of lower valve body 250 to provide pressurized fluid for bladder control, while a passage 294 is provided thorough flanges 252 to communicate with the downstream pipe and provide an indication of downstream pressure, again for bladder control. These provide the control connections necessary for bladder control as described for the valve of Fig. 2. Both bladder 266 and gate bladder 285 may
15 be controlled with a single pilot valve. Alternately, each bladder may be independently controlled.

In order to increase the capacity of a valve as shown in Fig. 16, rather than merely making the upper valve body and the flow passages larger, which quickly adds to the weight of the valve, several upper valve bodies may be
20 connected to the same lower valve body to provide, in effect, several valves which operate in parallel. Fig. 18 shows a basic valve of this construction with a lower valve body 300 with flange 301 adapted to be connected to an upstream pipe and flange 302 adapted to be connected to a downstream pipe. Two upper valve bodies 303 and 304 are formed at right angles to the lower
25 valve body 300 and extend from opposite sides thereof. Each of the upper bodies 303 and 304 houses an inlet chamber 305 and an outlet chamber 306, separated by a partition plate 307. Receptacles 308 are provided to form passages from the inlet chamber 305, around partition plate 307 to outlet chamber 306, and to receive the elastomeric flow control means, not shown
30 in Fig. 18. The inlet chambers 305 extend into the lower valve body 300 to connect with inlet opening 310, while walls 311 form an outlet passage 312 from outlet chambers 306 to outlet opening 313. The outlet passage 312 preferably extends concentrically through the inlet chambers 305.

35 The outlet chamber end plates, outlet chamber gate valves, cover sleeves, etc. as shown in Figs. 16 and 17 are not shown in Fig 18, Fig. 18 merely indicating the construction of the valve for multiple arrangements of

parallel flow control means. Any of the variations shown for the various valves can be used in the valve of Fig. 18. The arrows show the normal fluid flow through the valve.

5 The number and orientation of the upper valve bodies provided in a valve of the type shown in Fig. 18 can vary as desired. If two upper valve bodies are used on opposite sides as shown, they may both be located in a horizontal plane, or one may extend upwardly and one downwardly at various angles, as desired.

10 Fig. 19 shows further variations on the valve of Figs. 16 and 17. The lower valve body 320 of Fig. 19, with flanges 321 and 322, is similar to the lower valve body of Figs. 16 and 17. Upper valve body 323 includes two partition plates 324 and 325 and two sets of receptacles 326 and 327 to provide passages around partition plates 324 and 325, respectively. With two partition plates, a first inlet chamber 326 is formed upstream of partition plate 324 and communicates with valve inlet opening 327. A first outlet chamber 328 which also forms a second inlet chamber is formed between partition plates 324 and 325, and a second outlet chamber 329 is formed which corresponds to outlet chamber 257 of Fig. 16. An outlet passage 330 formed by walls 331 connect second outlet chamber 329 to valve outlet opening 332. Outlet chamber end wall 333 is secured to the end of upper valve body 323 such as by bolts 334. A gasket 335 seals the connection. An outlet gate 336 is positioned in outlet chamber 329 for sliding axial movement in the outlet chamber between a closed position as shown in Fig. 19 wherein a portion of outlet gate 336 fits into the end of outlet passage 330 to block such passage and thereby block all flow of fluid through the valve, and an open position wherein the gate 336 is moved away from partition plate 325 and outlet passage 330 to open the outlet passage to flow of fluid from outlet chamber 329. Seal 337 ensures a good seal around the entrance to the outlet passage in closed position. Outlet gate valve 336 is shown as 25 hydraulically operated with pressurized fluid being supplied through passage 338 into space 339 between the valve and end plate 333. The edge 340 of gate valve 336 is tapered, as shown, so that fluid passing through receptacle 327 will exert pressure on such surface tending to move the valve away from partition plate 325 toward its open position. By controlling the pressure of the fluid in space 339, the valve can be controlled to allow it to slide open under fluid pressure applied to surface 340 and, once open, pressure applied 35

2080815

to the entire lower surface of the valve, or to move the valve to its closed position. O-ring 341 seals space 339.

5 Valve 336 includes an air vent tube 342 extending therethrough and extending through end wall 333 with O-ring 343 providing a seal where tube 342 passes through end wall 333. Any standard air vent valve may be attached to the end of tube 342 outside the valve, or a valve 345 may be mounted for sliding movement in tube 342. Valve 345 is shown in closed position in Fig. 19 with lower shoulders 346 abutting and sealing against seal 347, and float 348 in float chamber 349 in sealing position against vent hole 10 350. In such position, the vent valve is closed against any backflow of fluid in outlet passage 330, or against flow of fluid out through tube 342 due to flow of pressurized fluid through outlet chamber 329 and outlet passage 330. With gate valve 336 closed and no pressure in outlet passage 330, vent valve 345 can move downwardly in tube 342, as can float 348 in float chamber 349, to 15 allow flow of air into outlet passage 330. Fins 345 guide the upper end vent valve in tube 342 as it slides therein.

Elastomeric flow control means as previously described will be provided in each set of receptacles 326 and 327, only bladder 350 in receptacles 326 20 being shown, to provide primary flow control and pressure control through the valve. Bladder 350 is shown with reinforcement plates 351 as previously described. The bladders or other elastomeric flow control means are held in the receptacles 326 by cover ring 352 while the bladder or other elastomeric flow control means are held in the receptacles 327 by cover ring 353. While reinforcement is shown in bladder 350, reinforcement may or may not be 25 used, and the bladder used in receptacles 327 may or may not have such reinforcement.

Lower valve body 320 also includes a clean-out outlet 355.

Fig. 20 shows an alternate outlet gate valve that can be used with the embodiment of Figs. 16-19. Valve 360 is made of elastomeric material 361 30 with flanges 362 to be sandwiched between upper valve body 323 and end plate 333 in place of gasket 335. This anchors valve 360 in place. A flat elastomeric bottom 363 with reinforcement plate 364 is sized to fit sealingly against the partition plate 325 in the outlet chamber 329. An air vent tube 365 is provided similarly to tube 342 in Fig. 19. When installed, the valve creates a space between the bottom of the valve and the end plate 333, 35 similar to space 339 and is operated by controlling the pressure of pressurized fluid in such space, as described.

2080815

With any of the embodiments shown in Figs. 16-19, the gate valve could be provided without provision for an air relief valve if desired. The particular use of the valve and its orientation will determine if an air relief valve is desirable.

5 If the valve body is made as a casting and a gate valve is to sealingly slide in any portion thereof, rather than machining the valve body to provide a smooth sliding surface, a sleeve can be inserted therein to form a smooth surface. With any of the sliding valves, mechanical locking means can be provided to lock a valve in a desired open or closed position. Further, if
10 desired, the outlet openings or inlet openings of the passages can be provided with grates or screens. The provision of grates at the outlet openings will tend to prevent the elastomeric flow control means from ballooning. In addition, various of the gate valves, or elastomeric flow control means wherein a reinforcing plate is provided, may be spring loaded to provide
15 desired operation characteristics in specialized applications.

Further, while the valves illustrated have been described with respect to inlets and outlets, the valves under most condition can be operated in reverse configuration so that the outlet becomes the inlet and visaversa.

It will be understood that with all embodiments, gaskets may be
20 provided where needed, although not shown, such as between the valve body and the reducers and between the insert and the partition plate. Also bearings or packing glands may be added as desired to rotating parts such as the butterfly valve mounting or the various rotating shafts.

Whereas this invention is here illustrated and described with specific
25 reference to embodiments thereof presently contemplated as the best mode of carrying out such invention in actual practice, it is to be understood that various changes may be made in adapting the invention to different embodiments without departing from the broader inventive concepts disclosed herein and comprehended by the claims that follow.

30

35

We claim:

1. A flow control and pressure reducing valve, comprising:
 - a valve body having an inlet chamber and an outlet chamber therein;
 - a partition within said valve body separating the inlet chamber and outlet chamber;
 - a plurality of tapered receptacles extending through the valve body from a relatively small inner end which opens to the inlet chamber, the partition, and the outlet chamber, to a relatively large outer end opening to outside the valve body in an access opening, whereby flow control means can be placed in each receptacle from outside the valve body through said access opening, and whereby the receptacles each form a passage extending through the valve body from the inlet chamber to the outlet chamber around the partition
 - elastomeric flow control means located in each of said receptacles and responsive to pressurized fluid introduced into said flow control means to controllably restrict said passage;
 - means for supplying pressurized fluid to said flow control means for controllably restricting each of said passages to thereby control flow of fluid through the valve; and
 - a cover for covering and sealing said access openings.
2. A flow control and pressure reducing valve according to Claim 1, wherein the tapers of each receptive are such that if such tapers were continued inwardly of the inner end of the receptacle, they would all intersect on the central axis of the valve body.
3. A flow control and pressure reducing valve according to Claim 1, wherein each receptacle is in the form of a truncated cone extending radially through the valve body.
4. A flow control and pressure reducing valve according to Claim 1, wherein the tapers of each receptacle are such that if such tapers were continued inwardly of the inner end of the receptacle, they would all intersect on a circle whose center lies on the central axis of the valve body.

5. A flow control and pressure reducing valve according to Claim 1, additionally including at least one conduit means having an open end in communication with at least one receptacle and positioned such that its open end is normally sealed by the flow control means in the receptacle, but, if a flow control means ruptures, the ruptured flow control means will no longer seal the open end of the conduit means and pressurized fluid from the inlet of the valve will enter the conduit means, and sensing means in communication with said conduit means to sense if pressurized fluid enters said conduit means and to provide a signal upon sensing fluid entering the conduit means.
6. A flow control and pressure reducing valve according to Claim 1, wherein the particular divides each passage into equal size inlet and outlet portions.
7. A flow control and pressure reducing valve according to Claim 1, wherein the elastomeric flow control means is at least one bladder means configured to fit into and be received by the receptacles.
8. A flow control and pressure reducing valve according to Claim 7, wherein the at least one bladder means is a plurality of bladders, each configured to fit into and extend between several adjacent receptacles.
9. A flow control and pressure reducing valve according to Claim 8, wherein each of the plurality of bladders has its own means for supplying pressurized fluid to the bladder.
10. A flow control and pressure reducing valve according to Claim 8, wherein each of the means for supplying pressurized fluid to a bladder comprises a conduit communicating with the interior of the bladder and adapted to be attached to a source of pressurized fluid.
11. A flow control and pressure reducing valve according to Claim 1, wherein the elastomeric flow control means are bladder means configured to fit into and be received by the receptacles.

12. A flow control and pressure reducing valve according to Claim 11, wherein a plurality of adjacent bladder means are formed so as to be communicatively joined.
13. A flow control and pressure reducing valve according to Claim 1, additionally including an inlet gate; means for mounting the inlet gate in the inlet chamber of the valve body; and means for positioning the inlet gate in the inlet chamber so as to restrict to a desired degree the flow of fluid through the inlet chamber of the valve.
14. A flow control and pressure reducing valve according to Claim 1, additionally including an outlet gate; means for mounting the outlet gate in the outlet chamber of the valve body; and means for positioning the outlet gate in the outlet chamber so as to restrict to a desired degree the flow of fluid through the outlet chamber of the valve.
15. A flow control and pressure reducing valve according to Claim 1, additionally including passage means extending from the outlet chamber to communication with the atmosphere outside the valve body, and air flow control means positioned in the passage to allow selective flow of air between the passage and the atmosphere, but block flow of fluid being controlled by the valve from the valve to the atmosphere.
16. A flow control and pressure reducing valve, comprising:
a valve body having an inlet chamber and an outlet chamber therein;
a partition within said valve body separating the inlet chamber and outlet chamber;
a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber around the partition, each of said passages being divided by the partition into an inlet portion opening into the inlet chamber and an outlet portion opening into the outlet chamber, and each of said passages extending through the valve body and opening through an access opening to outside the valve body to form a receptacle for an elastomeric flow control bladder which can be placed in the receptacle from outside the valve body;
elastomeric flow control bladders configured to fit within the receptacles and responsive to pressurized fluid introduced thereinto to controllably move a portion thereof in

each receptacle between a position wherein said portion is seated against the partition dividing the inlet portion of the passage from the outlet portion of the passage to thereby close the passage, and a position wherein said portion is displaced from the partition a preset maximum distance to fully open said passage, to thereby control flow of fluid through said passages;

means for supplying pressurized fluid to said flow control bladders for controllably restricting each of said passages to thereby control flow of fluid through the valve; and

means for securing the flow control bladders in the receptacles.

17. A flow control and pressure reducing valve according to Claim 16, wherein the bladder is at least one elongate bladder having a plurality of formed bladder extensions extending from one side thereof and each extension being configured to be received in a receptacle and spaced along the bladder so that the bladder can extend about the outside of the valve body over a plurality of access openings with bladder extensions extending through each of the covered access openings into the respective receptacles covered by the bladder, and wherein the means for securing the flow control bladder in the receptacles holds the at least one bladder in place over the receptacles.

18. A flow control and pressure reducing valve according to Claim 17, wherein a plurality of elongate bladders are provided, each elongate bladder covering a plurality of adjacent receptacles.

19. A flow control and pressure reducing valve, comprising:

a valve body having an inlet chamber and an outlet chamber therein;

a partition within said valve body separating the inlet chamber and outlet chamber;

a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber around the partition, said passages each being divided by the partition into an inlet portion opening into the inlet chamber and an outlet portion opening into the outlet chamber;

elastomeric flow control means located in said passages and responsive to pressurized fluid introduced into said flow control means to controllably restrict said passage means;

means for supplying pressurized fluid to said flow control means for controllably restricting each of said passages to thereby control flow of fluid through the valve;

an inlet gate;

means axially mounting the inlet gate at least partially in the inlet chamber for limited travel in the axial direction between a closed position wherein the inlet gate substantially blocks flow of fluid through the inlet chamber of the valve and an open position wherein the inlet gate does not substantially block flow of fluid through the inlet chamber of the valve; and

means for controllably moving the inlet gate within the inlet chamber to positions between its open and closed positions.

20. A flow control and pressure reducing valve according to Claim 19, additionally including:

an outlet gate;

means axially mounting the outlet gate in the outlet chamber for limited travel in the axial direction between a closed position wherein the outlet gate substantially blocks flow of fluid through the outlet chamber of the valve and an open position wherein the outlet gate does not substantially block flow of fluid through the outlet chamber of the valve.

21. A flow control and pressure reducing valve according to Claim 20, wherein the means for mounting the inlet gate in the inlet chamber is a mounting shaft extending axially into the inlet chamber, and wherein the inlet gate includes a mounting hub adapted to be received on said mounting shaft for controlled longitudinal movement therealong.

22. A flow control and pressure reducing valve according to Claim 21, wherein the mounting shaft is threaded and the mounting hub is hollow and internally threaded so as to be received on the threaded mounted shaft, and wherein the means for moving the inlet gate in the inlet chamber is means to rotate the inlet gate in the chamber to cause longitudinal movement of the inlet gate along the shaft.

23. A flow control and pressure reducing valve according to Claim 22, wherein the threads on the mounting shaft are discontinuous and wherein holes are provided through the mounting hub so that material which builds up on the threaded shaft is released from the shaft as the hub rotates thereon and is exuded through the holes.

24. A flow control and pressure reducing valve according to Claim 19, wherein the means for controllably moving the inlet gate moves the inlet gate hydraulically.

25. A flow control and pressure reducing valve according to Claim 24, wherein a sealing portion of the inlet chamber is cylindrical and has a first diameter adjacent the partition and the inlet portions of the passages, wherein a reducer is secured to the end of the valve adjacent the inlet chamber of the valve, said reducer providing a cylindrical reducer sealing portion of a second, reduced diameter, wherein the inlet gate has one end sized to sealingly and slidably fit within the inlet chamber sealing portion and an opposite end sized to sealingly and slidably fit within the reducer sealing portion, the lengths of the inlet chamber sealing portion and reducer sealing portion being such to allow the gate to move between a closed position wherein the one end of the gate is adjacent the partition [plate] and blocks flow through the inlet chamber to the inlet portions of the passages and an open position wherein the one end of the gate is moved away from the partition to allow flow of fluid into the inlet portion of the passages.

26. A flow control and pressure reducing valve according to Claim 25, wherein a fluid tight chamber is formed between the two ends of the gate and the inlet chamber and the reducer whereby pressurized fluid introduced into said fluid tight chamber controls movement of the gate between open and closed positions.

27. A flow control and pressure reducing valve, comprising:
a valve body having an inlet chamber and an outlet chamber therein;
a partition within said valve body separating the inlet chamber and outlet chamber;

a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber around the partition, said passages each being divided by the partition into an inlet portion opening into the inlet chamber and an outlet portion opening into the outlet chamber;

elastomeric flow control means located in said passages and responsive to pressurized fluid introduced into said flow control means to controllably restrict said passages;

means for supplying pressurized fluid to said flow control means for controllably restricting each of said passages to thereby control flow of fluid through the valve;

an outlet gate;

means axially mounting the outlet gate at least partially in the outlet chamber for limited travel in the axial direction between a closed position wherein the outlet gate substantially blocks flow of fluid through the outlet chamber of the valve and an open position wherein the outlet gate does not substantially block flow of fluid through the outlet chamber of the valve; and

means for controllably moving the outlet gate within the outlet chamber to positions between its open and closed positions.

28. A flow control and pressure reducing valve according to Claim 27, wherein the means for controllably moving the outlet gate moves the outlet gate hydraulically.

29. A flow control and pressure reducing valve according to Claim 27, wherein the means for mounting the outlet gate in the outlet chamber is a mounting shaft extending axially into the outlet chamber, and wherein the outlet gate includes a mounting hub adapted to be received on said mounting shaft for longitudinal movement therealong.

30. A flow control and pressure reducing valve according to Claim 27, wherein the outlet gate, when in closed position, forms a support adjacent the openings of the receptacle means into the outlet chamber to reduce ballooning of the elastomeric flow control means into the outlet chamber.

31. A flow control and pressure reducing valve according to Claim 27, wherein the outlet gate includes a grate in the outlet chamber, elastomeric outlet gate means and means for supplying pressurized fluid to the elastomeric outlet gate means to move such elastomeric outlet gate means against the grate to block flow of fluid through said grate when it is desired to block flow of fluid through the outlet chamber.

32. A flow control and pressure reducing valve, comprising:

a valve body having an inlet chamber and an outlet chamber therein;

a partition within said valve body separating the inlet chamber and outlet chamber;

a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber around the partition, said passages each being divided by the partition into an inlet portion opening into the inlet chamber and an outlet portion opening into the outlet chamber;

elastomeric flow control means located in said passages and responsive to pressurized fluid introduced into said flow control means to controllably restrict said passages;

means for supplying pressurized fluid to said flow control means for controllably restricting each of said passages to thereby control flow of fluid through the passages;

an auxiliary passage extending through the partition; and

valve means within the auxiliary passage to control flow of fluid through the auxiliary passage.

33. A flow control and pressure reducing valve according to Claim 32, wherein the auxiliary passage extends through the inlet chamber, and additionally including inlet gate means mounted in said auxiliary passage to control flow of fluid from the auxiliary passage into the inlet chamber.

34. A flow control and pressure reducing valve according to Claim 33, wherein the auxiliary passage extends through the outlet chamber of the valve, and additionally including

outlet gate means mounted in the auxiliary passage to control flow of fluid from the outlet chamber of the valve into the auxiliary passage.

35. A flow control and pressure reducing valve, comprising:

- a valve body having an inlet chamber and an outlet chamber therein;
- a partition within said valve body separating the inlet chamber and the outlet chamber;
- a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber, said passages each having an inlet opening at one end whereby the passage opens into the inlet chamber and an outlet opening at the other end whereby the passage opens into the outlet chamber;

- a first cylindrical inlet chamber sealing portion of a first diameter;

- a second cylindrical inlet chamber sealing portion of a second diameter spaced axially along the inlet chamber from the first cylindrical inlet chamber sealing portion;

- a gate, said gate having a gate first diameter portion sealingly and slidingly received in said first cylindrical inlet chamber sealing portion and a gate second diameter portion sealingly and slidingly received in said second cylindrical inlet chamber sealing portion, the relative lengths of the gate first diameter portion, the gate second diameter portion, the first cylindrical inlet chamber sealing portion, and the second cylindrical inlet chamber sealing portion being such to allow the gate to move between a closed position wherein one end of the gate is adjacent the partition and blocks flow through the inlet chamber to the inlet openings of the passages and an open position wherein the one end of the gate is moved away from the partition to allow flow through the inlet chamber and into the inlet openings of the passages, and so that a sealed control chamber is formed between the gate and the inlet chamber, said control chamber varying in volume as said gate slides within the inlet chamber; and

- means for controlling flow of a control fluid into and out of said control chamber to control movement of the gate within the inlet chamber.

36. A flow control and pressure reducing valve, comprising:

- a valve body having an inlet chamber and an outlet chamber therein;

- a partition within said valve body separating the inlet chamber and the outlet chamber;

a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber, said passages each having an inlet opening at one end whereby the passage opens into the inlet chamber and an outlet opening at the other end whereby the passage opens into the outlet chamber;

a first cylindrical outlet chamber sealing portion of a first diameter;

a second cylindrical outlet chamber sealing portion of a second diameter spaced axially along the outlet chamber from the first cylindrical outlet chamber sealing portion;

a gate, said gate having a gate first diameter portion sealingly and slidably received in said first cylindrical outlet chamber sealing portion and a gate second diameter portion sealingly and slidably received in said second cylindrical outlet chamber sealing portion, the relative lengths of the gate first diameter portion, the gate second diameter portion, the first cylindrical outlet chamber sealing portion, and the second cylindrical outlet chamber sealing portion being such to allow the gate to move between a closed position wherein one end of the gate is adjacent the partition and blocks flow through the outlet openings of the passages and the outlet chamber and an open position wherein the one end of the gate is moved away from the partition to allow flow through the outlet openings of the passages and the outlet chamber, and so that a sealed control chamber is formed between the gate and the outlet chamber, said control chamber varying in volume as said gate slides within the outlet chamber; and

means for controlling flow of a control fluid into and out of said control chamber to control movement of the gate within the inlet chamber.

37. A flow control and pressure reducing valve, comprising:

a lower valve body having an inlet opening and an outlet opening;

means preventing communication between the inlet opening and outlet opening through the lower valve body;

an upper valve body secured to the lower valve body and having an inlet chamber and an outlet chamber therein, said inlet chamber being in flow communication with the inlet opening of the lower valve body and the outlet chamber being in flow communication with the outlet opening of the lower valve body;

a partition means within the upper valve body separating the inlet chamber and outlet chamber;

a plurality of tapered receptacles extending through the upper valve body each having a relatively small inner end which opens to the inlet chamber, the partition means, and the outlet chamber, and a relatively large outer end opening to outside the upper valve body in an access opening, whereby flow control means can be placed in each receptacle from outside the upper valve body through said access opening, and whereby the receptacles each form a passage means extending through the upper valve body from the inlet chamber to the outlet chamber around the partition means;

elastomeric flow control means located in each of said receptacle means and responsive to pressurized fluid introduced into said flow control means for controllably restricting each of said passage means to thereby control flow of fluid through the valve; and

means for covering and sealing said access openings.

38. A flow control and pressure reducing valve according to Claim 37, wherein the upper valve body extends perpendicularly to the lower valve body, and wherein the outlet passage extends from the outlet chamber through the partition means and the inlet chamber of the upper valve body to communicate with the outlet opening.

39. A flow control and pressured reducing valve according to Claim 38, wherein the upper valve body has an end adjacent the lower valve body and an outer end away from the lower valve body, wherein the valve includes an end wall at the outer end of the upper valve body, and wherein the outlet charmer is cylindrical and formed between partition means and the end wall.

40. A flow control and pressure reducing valve according to Claim 39, additionally including outlet gate means mounted in the outlet chamber, and means for positioning the outlet gate means in the outlet chamber so as to restrict to a desired degree the flow of fluid through the outlet chamber of the valve.

41. A flow control and pressure reducing valve, comprising:
- a valve body having an inlet chamber and an outlet chamber therein;
 - a partition within said valve body separating the inlet chamber and outlet chamber;
 - a plurality of passages extending through the valve body from the inlet chamber to the outlet chamber;
 - a gate;
 - a threaded shaft rotatably mounting the gate at least partially in at least one of the inlet chamber or outlet chamber of the valve for limited travel in the axial direction along the shaft between a closed position wherein the gate substantially blocks flow of fluid through the chamber and an open position wherein the gate does not substantially block flow of fluid through the chamber; circumferentially spaced teeth extending radially outwardly from the gate and extending longitudinally along the gate; and
 - means engaging the teeth for causing the gate to rotate on the threaded shaft for controllably moving the gate within the chamber to positions between its open and closed positions.
