STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH

The presently disclosed embodiments were made with government support under Grant 5DP1OD00027605, 5R37MH05938809, and 1RO1MH087986, which were awarded by the National Institute of Health; the Government has certain rights in the presently disclosed embodiments.

TECHNICAL FIELD

This presently disclosed embodiments relate generally to the discovery of pro-neurogenic compounds capable of promoting neurogenesis and/or reducing neuronal cell death.

BACKGROUND

It is now accepted that the adult vertebrate brain fosters the birth and functional incorporation of newly formed neurons (Goldman and Nottebohm, Proc Natl Acad Sci USA 1983, 80: 2390-2394; Paton and Nottebohm, Science 1984, 225, 1046-1048; Burd and Nottebohm, J Comp Neurol 1985, 240:143-152). However, it was long thought that no new neurons could be added to the adult mammalian brain. This dogma was challenged in the 1960's when autoradiographic evidence of new neuron formation in the hippocampal dentate gyrus, olfactory bulb, and cerebral cortex of the adult rat was presented (Altman, J. Science 1962, 135, 1127-1128; Altman, J. J Comp Neurol 1966, 128:431^174; Altman, Anat Rec 1963, 145:573-591; Altman and Das, J. Comp. Neurol. 1965, 124, 319-335; Altman and Das, J Comp Neurol 1966, 126:337-390). It is now accepted that within all mammalian species, including humans (Eriksson et al., Nat. Med. 1998, 4(11), 1313-1317), there are two major reservoirs of neuronal stem cells, one located in the subgranular zone (SGZ) of the hippocampal dentate gyrus and another in the subventricular zone (SVZ) (Gross, Natl. Rev. 2000, 1, 67-72). Neural stem cells in the SVZ facilitate formation of new neurons that migrate rostrally to populate the olfactory bulb, while neural stem cells in the SGZ

produce neurons that integrate locally in the granular layer of the dentate gyrus, a region of the hippocampus that exhibits lifelong structural and functional plasticity.

The process of new neuron formation in the adult mouse brain can be influenced by environmental, chemical and genetic variables. As demonstrated by Gage and colleagues, neurogenesis in the adult mouse brain is enhanced when animals are exposed to an enriched environment (Kempermann et al., Nature 1997, 386, 493-495) or able to exercise voluntarily (van Praag et al., Nat. Neuro-sci. 1999, 2, 266-270). More recently, anti-depressant drugs have been shown to enhance levels of adult neurogenesis in animals, including humans (Schmidt et al., Behav Pharmacol. 2007 Sep;18(5-6):391-418; Boldrini et al., Neuropsychopharmacology 2009, 34, 2376-2389). Among many genes reported to impact adult neurogenesis is the gene encoding neuronal PAS domain protein 3 (NPAS3), a central nervous system (CNS)-specific transcription factor that has been associated with schizophrenia and bipolar disorder (Kamnasaran et al., J. Med. Genet. 2003, 40, 325-332; Pickard et al., Am. J. Med. Genet. B. Neuropsychiatr. Genet. 2005, 136B, 26-32; Pickard et al., Ann. Med. 2006, 38, 439-448; Pickard et al., Mol. Psychiatry 2009, 14, 874-884; Lavedan et al., Pharmacogenomics 2008, 9: 289-301). Animals missing both copies of the NPAS3 gene suffer a profound loss of adult hippocampal neurogenesis coupled with significant behavioral deficits (Pieper et al., Proc. Natl. Acad. Sci. USA 2005, 102, 14052-14057). Knowing that impaired post-natal neurogenesis elicits unfavorable phenotypic deficits, it is predicted that pro-neurogenic chemical compounds should exhibit favorable therapeutic benefits.

SUMMARY

This presently disclosed embodiments relate generally to compounds that promote the generation or the survival of existing neurons in the mammalian brain. For the purpose of simplicity these compounds are referred to as being pro-neurogenic. In certain embodiments, the compounds promote the generation or survival of neurons in the post-natal mammalian brain. In certain embodiments, the compounds promote the survival, growth, development and/or function of neurons, particularly CNS, brain, cerebral, and hippocampal neurons. In certain embodiments, the compounds stimulate post-natal hippocampal neurogenesis, which while not wishing to be bound by theory, is believed to represent a therapeutic target for a variety of neuropsychiatric and neurodegenerative diseases, including (but not limited to) schizophrenia,major depression, bipolar disorder, normal aging, epilepsy, traumatic brain injury, post-traumatic stress disorder, Parkinson's disease, Alzheimer's disease, Down syndrome, spinocerebellar ataxia, amyotrophic lateral sclerosis, Huntington's disease, stroke, radiation therapy, chronic stress, abuse of neuro-active drugs (such as alcohol, opiates, methamphetamine, phencyclidine, and cocaine), retinal degeneration, spinal cord

injury, and peripheral nerve injury. In certain embodiments, the compounds stimulate post-natal hypothalamic neurogenesis, which can provide therapeutic benefits in weight management, such as physiological weight loss associated with various conditions, including but not limited to, normal aging, chemotherapy, radiation therapy, stress, drug abuse, anorexia, as well as other diseases discussed herein.

Definitions

The term "mammal" includes organisms, which include mice, rats, cows, sheep, pigs, rabbits, goats, horses, monkeys, dogs, cats, and humans.

"An effective amount" refers to an amount of a compound that confers a therapeutic effect (e.g., treats, e.g., controls, relieves, ameliorates, alleviates, or slows the progression of; or prevents, e.g., delays the onset of or reduces the risk of developing, a disease, disorder, or condition or symptoms thereof) on the treated subject. The therapeutic effect may be objective (i.e., measurable by some test or marker) or subjective (i.e., subject gives an indication of or feels an effect/ An effective amount of the compound described above may range from about 0.01 mg/kg to about 1000 mg/kg, (e.g., from about 0.1 mg/kg to about 100 mg/kg, from about 1 mg/kg to about 100 mg/kg). Effective doses will also vary depending on route of administration, as well as the possibility of co-usage with other agents.

The term "halo" or "halogen" refers to any radical of fluorine, chlorine, bromine or iodine.

In general, and unless otherwise indicated, substituent (radical) prefix names are derived from the parent hydride by either (i) replacing the "ane" in the parent hydride with the suffixes "yl," "diyl," "triyl," "tetrayl," etc.; or (ii) replacing the "e" in the parent hydride with the suffixes "yl," "diyl," "triyl," "tetrayl," etc. (here the atom(s) with the free valence, when specified, is (are) given numbers as low as is consistent with any established numbering of the parent hydride). Accepted contracted names, e.g., adamantyl, naphthyl, anthryl, phenanthryl, furyl, pyridyl, isoquinolyl, quinolyl, and piperidyl, and trivial names, e.g., vinyl, allyl, phenyl, and thienyl are also used herein throughout. Conventional numbering/lettering systems are also adhered to for substituent numbering and the nomenclature of fused, bicyclic, tricyclic, polycyclic rings.

The following definitions are used, unless otherwise described. Specific and general values listed below for radicals, substituents, and ranges, are for illustration only; they do not exclude other defined values or other values within defined ranges for the radicals and substituents. Unless otherwise indicated, alkyl, alkoxy, alkenyl, and the like denote both straight and branched groups.

The term "alkyl" refers to a saturated hydrocarbon chain that may be a straight chain or branched chain, containing the indicated number of carbon atoms. For example, C_1-Ce alkyl indicates that the group may have from 1 to 6 (inclusive) carbon atoms in it. Any atom can be optionally substituted, e.g., by one or more subsituents. Examples of alkyl groups include without limitation methyl, ethyl, w-propyl, i*so*propyl, and *tert*-butyl.

As used herein, the term "straight chain C_{n-m} alkylene," employed alone or in combination with other terms, refers to a non-branched divalent alkyl linking group having n to m carbon atoms. Any atom can be optionally substituted, e.g., by one or more subsituents. Examples include methylene (i.e., $-CH_2-$).

The term "haloalkyl" refers to an alkyl group, in which at least one hydrogen atom is replaced by halo. In some embodiments, more than one hydrogen atom (e.g., 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, or 14) are replaced by halo. In these embodiments, the hydrogen atoms can each be replaced by the same halogen (e.g., fluoro) or the hydrogen atoms can be replaced by a combination of different halogens (e.g., fluoro and chloro). "Haloalkyl" also includes alkyl moieties in which all hydrogens have been replaced by halo (sometimes referred to herein as perhaloalkyl, e.g., perfluoroalkyl, such as trifluoromethyl). Any atom can be optionally substituted, e.g., by one or more substituents.

As referred to herein, the term "alkoxy" refers to a group of formula -O(alkyl). Alkoxy can be, for example, methoxy ($-OCH_3$), ethoxy, propoxy, isopropoxy, butoxy, iso-butoxy, sec-butoxy, pentoxy, 2-pentoxy, 3-pentoxy, or hexyloxy. Likewise, the term "thioalkoxy" refers to a group of formula -S(alkyl). Finally, the terms "haloalkoxy" and

"thioalkoxy" refer to -0(haloalkyl) and -S(haloalkyl), respectively. The term "sulfhydryl" refers to -SH. As used herein, the term "hydroxyl," employed alone or in combination with other terms, refers to a group of formula -OH.

The term "aralkyl" refers to an alkyl moiety in which an alkyl hydrogen atom is replaced by an aryl group. One of the carbons of the alkyl moiety serves as the point of attachment of the aralkyl group to another moiety. Any ring or chain atom can be optionally substituted e.g., by one or more substituents. Non-limiting examples of "aralkyl" include benzyl, 2-phenylethyl, and 3-phenylpropyl groups.

The term "alkenyl" refers to a straight or branched hydrocarbon chain containing the indicated number of carbon atoms and having one or more carbon-carbon double bonds. Any atom can be optionally substituted, e.g., by one or more substituents. Alkenyl groups can include, e.g., vinyl, allyl, 1-butenyl, and 2-hexenyl. One of the double bond carbons can optionally be the point of attachment of the alkenyl substituent.

The term "alkynyl" refers to a straight or branched hydrocarbon chain containing the indicated number of carbon atoms and having one or more carbon-carbon triple bonds. Alkynyl groups can be optionally substituted, e.g., by one or more substituents. Alkynyl groups can include, e.g., ethynyl, propargyl, and 3-hexynyl. One of the triple bond carbons can optionally be the point of attachment of the alkynyl substituent.

The term "heterocyclyl" refers to a fully saturated monocyclic, bicyclic, tricyclic or other polycyclic ring system having one or more constituent heteroatom ring atoms independently selected from O, N (it is understood that one or two additional groups may be present to complete the nitrogen valence and/or form a salt), or S. The term "heteroaryl" refers to an aromatic monocyclic, bicyclic (2 fused rings), tricyclic (3 fused rings), or polycyclic (> 3 fused rings) hydrocarbon groups having one or more heteroatom ring atoms independently selected from O, N (it is understood that one or two additional groups may be present to complete the nitrogen valence and/or form a salt), or S. One or more ring atoms can be optionally substituted, e.g., by one or more substituents.

Examples of heteroaryl groups include, but are not limited to, 2H-pyrrolyl, 3H-indolyl, 4H-quinolizinyl, acridinyl, benzo[b]thienyl, benzothiazolyl, β-carbolinyl, carbazolyl, coumarinyl, chromenyl, cinnolinyl, dibenzo[b,d]furanyl, furazanyl, furyl, imidazolyl, imidizolyl, indazolyl, indolyl, isobenzofuranyl, isoindolyl, isoquinolyl, isothiazolyl, isoxazolyl, naphthyridinyl, oxazolyl, perimidinyl, phenanthridinyl, phenanthrolinyl, phenarsazinyl, phenazinyl, phenothiazinyl, phenoxathiinyl, phenoxazinyl, phthalazinyl, pteridinyl, purinyl, pyranyl, pyrazinyl, pyrazolyl,

The terms "arylcycloalkyl" and "arylheterocyclyl" refer to bicyclic, tricyclic, or other polycyclic ring systems that include an aryl ring fused to a cycloalkyl and heterocyclyl, respectively. Similarly, the terms "heteroarylheterocyclyl," and "heteroarylcycloalkyl" refer to bicyclic, tricyclic, or other polycyclic ring systems that include a heteroaryl ring fused to a heterocyclyl and cycloalkyl, respectively. As used herein, the term "cyano," employed alone or in combination with other terms, refers to a group of formula -CN, wherein the carbon and nitrogen atoms are bound together by a triple bond.

In general, when a definition for a particular variable includes both hydrogen and non-hydrogen (halo, alkyl, aryl, etc.) possibilities, the term "substituent(s) other than hydrogen" refers collectively to the non-hydrogen possibilities for that particular variable.

The term "substituent" refers to a group "substituted" on, e.g., an alkyl, haloalkyl, cycloalkyl, heterocyclyl, heterocycloalkenyl, cycloalkenyl, aryl, or heteroaryl group at any atom of that group. In one aspect, the substituent(s) on a group are independently any one single, or any combination of two or more of the permissible atoms or groups of atoms delineated for that substituent. In another aspect, a substituent may itself be substituted with any one of the above substituents.

Further, as used herein, the phrase "optionally substituted" means unsubstituted (e.g., substituted with a H) or substituted. As used herein, the term "substituted" means that a hydrogen atom is removed and replaced by a substituent. It is understood that substitution at a given atom is limited by valency.

Descriptors such as "C6-C10 aryl that is optionally substituted with from 1-4 independently selected R^b" (and the like) is intended to include both an unsubstituted C6-C10 aryl group and a *Ce*-C10 aryl group that is substituted with from 1-4 independently selected R^b. The use of a substituent (radical) prefix names such as alkyl without the modifier "optionally substituted" or "substituted" is

understood to mean that the particular substituent is unsubstituted. However, the use of "haloalkyl" without the modifier "optionally substituted" or "substituted" is still understood to mean an alkyl group, in which at least one hydrogen atom is replaced by halo.

In some embodiments, R^b can be as defined in any one, two, three, or all of **(aa)** through **(dd)**. For example, R^b can be as defined in **(aa)** and **(bb)** or combinations thereof.

The phrase "Cy is a saturated, partially unsaturated or aromatic carbocyclic or heterocyclic ring system" in the definition of R^e is understood to include each of the rings systems defined above (e.g., Cy can be coumarinyl or the ring component of biotin optionally substituted as defined anywhere herein).

The details of one or more embodiments are set forth in the description below. Other features and advantages of the presently disclosed embodiments will be apparent from the description and from the claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1: Pulse-chase analysis of BrdU-labeling identified magnitude and timing of cell death following birth of new neurons in the dentate gyrus. 12 week old wild type male C57/B6 mice were individually housed without access to running wheels and injected on day 0 with BrdU (50 mg/kg, i.p.). Neural precursor cell proliferation in the dentate gyrus (DG) subgranular zone (SGZ) and granular layer (GL) was subsequently monitored through immunohistochemistry for BrdU on days 1, 5, 10, 15, 20, and 25 days post-injection. Four mice were evaluated at each time point, and 25-30 adjacent coronal sections through the hippocampus (progressing posteriorly from the point where the suprapyramidal and infrapyramidal blades are joined at the crest region and the dentate gyrus is oriented horizontally beneath the corpus callosum) from each mouse were examined. On days 1 and 5, almost 100% of BrdU-positive cells within the DG were localized in the SGZ. The total number of cells decreased approximately 40% between days 1 and 5, in accordance with the appearance of apoptotic cell bodies in the SGZ. By day 10, some BrdU positive cells had migrated into the GL, with no significant change in total number of BrdU-positive cells in the DG. By day 15, BrdU-positive cells in the SGZ declined as the number of BrdU-positive cells in the GL stayed constant, suggesting that some of the cells migrating out of the SGZ and into the GL between days 10 and 15 underwent apoptosis. This trend continued through days 20-25. These results indicated that daily injection of BrdU over a one week period of continuous molecule infusion, a time period during which 40% of newborn cells in the SGZ normally die, would allow detection of compounds that enhance either proliferation or survival of newborn cells in the dentate gyrus.

Figure 2: Surgical placement of cannula and pumps did not affect hippocampal neurogenesis or survival of newborn neurons on the contralateral side of the brain. Mice infused with vehicle (artificial cerebrospinal fluid) over seven days by means of surgically implanted Alzet osmotic minipumps (Vehicle Infusion, n=5) displayed no difference in hippocampal neural precursor cell proliferation, as assessed by BrdU incorporation normalized for dentate gyrus volume, from mice treated identically except not having undergone surgery (No Surgery, n=4). When Alzet osmotic minipumps were loaded with fibroblast growth factor 2 (FGF-2; 10 mg/mL) (n=5), however, hippocampal neural precursor cell proliferation roughly doubled with respect to both of the other two groups(*, $p<0.001$, Student's /test).

Figure 3: Ectopic incorporation of BrdU served to eliminate molecules from further consideration. Immunohistochemical staining of BrdU in the hippocampal field should normally be restricted to the SGZ of the dentate gyrus, as shown on the left. The *in vivo* neurogenic screen employed was designed to detect small molecules that selectively stimulated BrdU incorporation into replicating cells of the SGZ. Infrequently, some compounds exhibited non-specific BrdU incorporation in ectopic regions, such as CA3, CA1, cortex, and striatum, as shown on the right. Any molecules that demonstrated ectopic incorporation of BrdU were eliminated from the study.

Figure 4: Screening of 100 pools of 10 compounds identified 10 pools with pro-neurogenic efficacy. The total number of BrdU-labeled cells in the dentate gyrus subgranular zone (SGZ) approximately doubled following seven day infusion with fibroblast growth factor 2 (FGF-2; 10 mg/mL) (n=5) relative to mice infused with vehicle (artificial cerebrospinal fluid (aCSF) (n=5). Each pool often compounds was tested for pro-neurogenic efficacy over a 7 day period in two independent mice at 10 μM concentration for each individual compound. Pools 7, 14, 18, 19, 41, 53, 54, 61, 69 and 70 displayed comparable stimulation of neural precursor cell proliferation as FGF-2 infusion. The majority of pools displayed no effect on hippocampal neural precursor cell proliferation.

Figure 5: Re-evaluation of positive pools verified statistical significance of enhanced BrdU-incorporation. Subsequent to their initial identification, pools 7, 14, 18, 19, 41, 53, 54, 61, 69, and 70 were re-evaluated in 2 additional mice each. Results shown are average with SEM of all 4 mice evaluated for each compound. All pools significantly (*, PO.001, Student's *t* test) stimulated neural precursor cell proliferation in the hippocampal dentate gyrus SGZ relative to vehicle control.

Figure 6: Pro-neurogenic pools were broken down to identify individual pro-neurogenic compounds. **(A)** *In vivo* evaluation of the ten individual compounds that composed pool #7 revealed that compound #3 stimulated either the proliferation or survival of neural precursor cells in the SGZ, whereas the remaining individual components of pool #7 did not. In this document this molecule is interchangeably referred to as "P7C3" or "Example 45 Compound." Each compound was infused at two different concentrations (100 μM (A and B) and 10 μM (C and **D))** in two mice each. Example 45 Compound showed either pro-neurogenic or neuroprotective activity at both concentrations. Below the graphs are typical results of BrdU incorporation in the SGZ, which is notably greater in animals infused with either Pool #7 or Example 45 Compound. **(B)** Molecular formulas and weights of individual pro-neurogenic compounds identified through the *in vivo* screen. **(C)** Re-supplied compounds were evaluated in three mice per compound at 10μM concentration to verify that the pro-neurogenic or neuroprotective effect on neural stem cells was not an artifact of storage conditions in the UTSWMC chemical compound library. Re-supplied compounds were verified to be 99% pure by mass spectrometry and shown to retain either pro-proliferative or neuroprotective properties *in vivo* in neural stem cells. All compounds significantly (*, PO.001, Student's *t* test) stimulated neural precursor cell proliferation in the hippocampal dentate gyrus SGZ relative to vehicle control.

Figure 7: Neurogenic efficacy of orally administered Example 45 Compound was dose-related. The graph on the top shows that the concentration of Example 45 Compound in brain tissue of mice that were administered compound by daily oral gavage for 7 consecutive days correlated with the dose of Example 45 Compound administered. The graph on the bottom shows that pro-neurogenic or neuroprotective efficacy of Example 45 Compound was roughly double that of vehicle control at doses ranging from 5 to 40 mg/kg. At decreasing dosage of Example 45 Compound the amount of neurogenesis decreased accordingly, until it reached levels no greater than vehicle control at compound doses below 1.0 mg/kg. Results shown are the average obtained from analysis of 5 adult wild type male mice at each dose.

Figure 8: Analysis of molecules related structurally to Example 45 Compound (P7C3) revealed a region of the compound that could be chemically modified without loss of *in vivo* activity. An *in vivo* SAR study was conducted using 37 chemical analogs of Example 45 Compound, each evaluated in 4 or 5 adult C57/B6 male mice. Some analogs revealed activity comparable to the parent compound, whereas others showed significantly diminished activity, or evidence of pro-neurogenic effect intermediate between vehicle and FGF controls. This exercise enabled

identification of regions of the parent compound that might be amenable to chemical modification without loss of activity. As an example, Example 62 Compound retained robust activity with the aniline ring of Example 45 Compound substituted by an anisidine. This derivative compound was exploited to yield a fluorescent derivative by attaching a coumarin moiety to the N-phenyl ring.

Figure 9: Activity of Example 62 Compound is enantiomer-specific. **(A)** (+) and (-) enantiomers of Example 62 Compound were prepared. **(B)** Evaluation of Example 62 Compound enantiomers showed that *in vivo* pro-neurogenic or neuroprotective efficacy was fully retained by the (+) enantiomer in a dose-dependent manner, while the (-) enantiomer showed diminished activity. Each enantiomer was evaluated at each dose in between 3 and 5 three month old adult wild type male C57/B6 mice.

Figure 10: Example 45 Compound enhances the survival of newborn neurons in the dentate gyrus. **(A)** Immunohistochemical staining for doublecortin (DCX), an antigen specifically and transiently expressed in proliferating hippocampal neural precursor cells when they become irreversibly committed to neuronal differentiation, was substantially increased in newborn neurons in mice that were administered Example 45 Compound (20 mg/kg) daily for 30 days by oral gavage, relative to that seen in mice that received vehicle only. These results are representative of 10 sections each from 5 mice in each group, and demonstrate that Example 45 Compound specifically promoted hippocampal neurogenesis. **(B)** Example 45 Compound enhances hippocampal neurogenesis by promoting survival of newborn neurons. Three month old wild type C57/B6 male mice were exposed to orally-delivered Example 45 Compound or vehicle for 30 days (n=5 animals / group), administered a single pulse of BrdU via IP injection (150 mg/kg), and then sacrificed 1 hour, 1 day, 5 days or 30 days later for immunohistochemical detection of BrdU incorporation into cells localized in the subgranular layer of the dentate gyrus. No significant differences were observed between groups at the 1 hour or 1 day time points, though at one day there was a trend towards increased BrdU+ cells in the Example 45 Compound-treated group. At the 5 day time point, by which time 40% of newborn neurons normally die, animals that received Example 45 Compound showed a statistically significant (*, PO.001, Student's *t* test) 25% increase in BrdU+ cells compared to the vehicle-only control group. This difference between groups progressed with time such that mice that received a daily oral dose of Example 45 Compound for 30 days, starting 24 hours after the pulse administration of BrdU, exhibited a 5-fold increase in the abundance of BrdU+ cells in the dentate gyrus relative to vehicle-only controls. In this longer-term trial, BrdU+ cells were observed both in the SGZ and the granular layer of the dentate gyrus.

Figure 11: Quantification of short term (1 hour pulse) BrdU incorporation and cleaved-caspase 3 (CCSP3) formation in the dentate gyrus showed that NPAS3-deficient mice have the same rate of proliferation of newborn cells in the dentate as wild type littermates (BrdU), but roughly twice the level of programmed cell death (CCSP3) (*, PO.01, Student's *t* test). Three 6 week old male mice (NPAS3-deficient or wild type littermates) in each group were evaluated.

Figure 12: Granule cell neurons in the dentate gyrus of NPAS3-deficient mice displayed morphological deficits in dendritic branching and spine density. **(A)** Golgi-Cox staining of the dentate gyrus illustrates that dendritic arborization of dentate gyrus granule cell neurons in *npas3*$^{-/-}$ mice is substantially less developed than in wild type littermates. Results shown are representative of 15 sections from five 12-14 week old adult male mice of each genotype. **(B)** In addition to obviously reduced dendritic length and branching, granular neurons in the dentate gyrus *oinpas3* $^{-/-}$ mice also exhibited significantly reduced spine density relative to wild type littermates (*, P < 0.00001, Student's *t* test). These genotype-specific differences were not exhibited by neurons in the CA1 region of the hippocampus.

Figure 13: In hippocampal slice preparation from *npas3*$^{-/-}$ mice, synaptic transmission was increased both in the outer molecular layer of the dentate gyrus **(A)** and the CA1 region of the hippocampus **(B)** relative to hippocampal slices from wild type mice. Extended treatment with Example 45 Compound normalized synaptic responses in the dentate gyrus but not the CA1 region of *npas3*$^{-/-}$ mice. Extended treatment with Example 45 Compound did not affect wild-type responses. Data are presented as the mean ±SEM. Each group consisted of 1 or 2 slice preparation from each of 5 mice.

Figure 14: Example 45 Compound has pro-neurogenic or neuroprotective efficacy in the dentate gyrus of NPAS3-deficient animals. Six 12 week old *npas3*$^{-/-}$ mice were orally administered vehicle or Example 45 Compound (20 mg/kg/d) for 12 days, and also injected daily with BrdU (50 mg/kg). At the end of day 12, mice were sacrificed and tissue was stained for BrdU and doublecortin (DCX). BrdU staining showed that Example 45 Compound increased the magnitude of neurogenesis in *npas3*$^{-/-}$ mice by roughly 4-fold, as graphically represented above (*, PO.001, Student's *t* test). DCX staining shows that Example 45 Compound also promoted more extensive process formation in differentiating neurons of the adult dentate gyrus in *npas3*$^{-/-}$ mice.

Figure 15: Golgi-Cox staining of neurons in the dentate gyrus shows that extended daily treatment ***ofnpas3*** $^{-/-}$ mice with Example 45 Compound (20 mg/kg/d) enhanced dendritic arborization. Hi-power micrographs are shown on top, and a lower power micrograph illustrating the entire dentate gyrus is shown below.

Figure 16: Measured thickness of hippocampal subfields in ***npas3*** $^{-/-}$ and wild type littermate mice that were treated with Example 45 Compound (20 mg/kg/d) or vehicle every day from embryonic day 14 until 3 months of age demonstrated that Example 45 Compound selectively increased the thickness of the dentate gyrus granular cell layer to a level approaching wild type thickness (*, PO.01, Student's ***t*** test), without affecting thickness of the pyramidal cell layers of CA1 or CA3 regions.

Figure 17: Immunohistochemical detection of cleaved caspase 3 (CCSP3), a marker of apoptosis, showed elevated levels of programmed cell death in the dentate gyrus of NPAS3-deficient animals. Apoptosis in NPAS3-deficient animals was inhibited by treatment with Example 45 Compound (20 mg/kg/d, p.o., for 12 days), whereas analogous treatment with vehicle alone had no effect. Images shown are representative of 10-12 sections evaluated per animal, with 3-5 eight-week-old male NPAS3-deficient mice per group.

Figure 18: Example 45 Compound acts mechanistically in the mitochondria. **(A)** Example 45 Compound preserved mitochondrial membrane potential following exposure to the calcium ionophore A23187 in a dose dependent manner as judged by fluorescent imaging of TMRM dye, a cell-permeant, cationic red-orange fluorescent dye that is readily sequestered by intact mitochondria. **(B)** The protective effect of Example 62 Compound was enantiomeric specific, with the (+) enantiomer retaining activity more so than the (-) enantiomer.

Figure 19: Example 45 Compound as compared to a known drug. **(A)** Both Example 45 Compound and the Dimebon anti-histamine enhanced hippocampal neurogenesis **(B),** and protected mitochondria from dissolution following toxic exposure to the calcium ionophore A23 187 **(C).** In the ***in vivo*** assay of neurogenesis the Example 45 Compound exhibited a higher ceiling of efficacy than the Dimebon anti-histamine. In all three assays, the Example 45 Compound performed with greater relative potency than the Dimebon anti-histamine.

Figure 20: Effect of Example 45 Compound in aged rats. **(A)** Example 45 Compound (20 mg/kg/d, i.p.) and BrdU (50 mg / kg, i.p.) were administered daily for 7 days to 12-18 month old Fisher 344 rats (n = 4 in each group). P7C3 promoted neural precursor cell proliferation by roughly 5 fold compared to vehicle. (*p < 0.001, Students t test). DCX staining demonstrates that P7C3 specifically promoted neuronal differentiation and dendritic branching. These micrographs were taken at the same magnification. Scale bar = 50 mm. Data are expressed as mean +/- SEM. **(B)** Latency to find the hidden platform in the Morris water maze task, as well as **(C)** swim speed and locomotor activity **(D)** in aged rats treated with P7C3 or vehicle both before and after 2 months of treatment did not differ between groups. Data are expressed as mean +/- SEM. **(E)** Quantification of food intake (upper panel) and fasting blood glucose levels in aged rats did not differ with respect to whether rats received P7C3 or vehicle. Data are expressed as mean +/- SEM.

Figure 21: Example 45 Compound Enhances Hippocampal Neurogenesis, Ameliorates Cognitive Decline, and Prevents Weight Loss in Terminally Aged Rats **(A)** Prior to treatment, both groups (n —23 for each group) showed similar frequency of crossings through the goal platform. After 2 months of treatment, however, Example 45 Compound-treated rats displayed a statistically significant increase of crossings through the goal platform area relative to vehicle treated rats. **(B)** Example 45 Compound-treated rats displayed significantly enhanced hippocampal neurogenesis, as assessed by BrdU incorporation, relative to vehicle treated rats. Many more of the BrdU-labeled cells were noted to have migrated into the granular layer in Example 45 Compound-treated rats in comparison to vehicle treated animals, consistent with their functional incorporation into the dentate gyms as properly wired neurons. The scale bar represents 50 mM. **(C)** Relative to vehicle-treated animals, Example 45 Compound-treated rats displayed significantly lower number of cleaved caspase 3-positive cells in the dentate gyrus, indicating that P7C3 was capable of inhibiting apoptosis in the aged rat brain. The scale bar represents 50 mM. **(D)** Relative to vehicle-treated animals, Example 45 Compound-treated rats were observed to maintain stable body weight as a function of terminal aging. In all graphs data are expressed as mean ± SEM.

Figure 22: Example 45 Compound Preserves Mitochondrial Membrane Potential in Parallel to Proneurogenic Activity U20S cells were loaded with tetramethylrhodamine methyl ester (TMRM) dye and then exposed to the calcium ionophore A23 187 either in the presence or absence of test compounds. Example 45 Compound **(A)** preserved mitochondrial membrane potential following exposure to the calcium ionophore A23 187 in a dose-dependent manner. The protective effect of P7C3 was enantiomeric specific. The (R)-enantiomer of another compound **(B)** blocked dye release at levels as low as 1 nM, whereas the (S)-enantiomer **(C)** failed to block dye release even at the highest drug dose tested (100 nM). A proneurogenic compound, P7C3A20 **(D)** exhibited dye

release protection at all doses tested, yet compounds having less proneurogenic activity (E and Γ) were less effective in preserving mitochondrial membrane potential at any test dose. Each compound was evaluated in triplicate with similar results.

Figure 23: Example 45 Compound Preserves Mitochondrial Membrane Potential in Cultured Primary Cortical Neurons. Cortical neurons cultures from rats on embryonic day 14 were loaded with tetramethylrhodamine methyl ester (TMRM) dye after 6 days of maturation. The top panels (no calcium ionophore) show that the dye alone did not affect the health of neurons. The remaining panels are from cells that were exposed to the calcium ionophore A23187 at time zero. With vehicle-alone, cortical neuron mitochondrial membrane potential was rapidly lost after exposure to the ionophore. Escalating doses of Example 45 Compound (A) preserved mitochondrial membrane potential following exposure to the calcium ionophore A23 187 in a dose dependent manner, with full protection achieved at 1 mM. The less active compound **(B)** was less effective in preserving mitochondrial membrane potential at any dose tested. Results shown are representative of 10 fields analyzed in each of 2 experimental runs for all conditions.

Figure 24. Example 45 Compound (P7C3) Provides Therapeutic Benefit in Animal Model of Amyotrophic Lateral Sclerosis (ALS). Female G93A SOD1 mice (n=30 in each group, with all mice sibling matched across treatment groups) were treated with either vehicle or P7C3 (10 mg/kg i.p. twice daily) starting at 40 days of age. P7C3-treated mice showed a significant delay in disease progression, as evidenced by the later age by which they dropped to 10% below their maximum weight (A). P7C3-treated mice also attain a neurological severity score of 2 at a later age than vehicle treated mice **(B),** again indicating that P7C3-treatment slows disease progression. This score is determined as follows: '0' = full extension of hind legs away from lateral midline when the test mouse is suspended by its tail, and can hold this for 2 seconds, suspended 2-3 times; '1' = collapse or partial collapse of leg extension towards lateral midline (weakness) or trembling of hind legs during tail suspension; '2' = toes curl under at least twice during walking of 12 inches, or any part of foot drags along cage bottom / table; '3' = rigid paralysis or minimal joint movement, foot not being used for forward motion; and '4' = mouse cannot right itself within 30 seconds from either side. With further disease progression, vehicle-treated mice show the expected decline in retention time on the accelerating rotarod, with retention time averaged across 4 trials **(C,** open bars). P7C3-treated mice, however, show a consistent trend towards improved performance on this task after onset of disease **(C,** filled bars), with statistically significant improvement on days 131, 138 and 145 (*, pO.001, Student's *t* Test). All graphical data shown above is mean +/- SEM, with statistical analysis conducted using the Student's *t* Test). As another means of disease progression,

walking gait was evaluated. **Figure 24D** shows footprint data from two sisters (VEH and P7C3) on day 92 (before disease onset) and day 118 (after disease onset). Front paws are dipped in red ink, and back paws are dipped in black ink. The VEH-treated mouse shows the expected decline in gait after disease onset on day 188, while her P7C3-treated sister showed preservation of normal gait on day 118. All analysis was conducted blind to treatment group.

Figure 25. Example 6a Compound (P7C3A20) Provides Therapeutic Benefit in Animal Model of Parkinson's Disease. Mice were treated with MPTP (30 mg/kg i.p.) or Vehicle only for 5 days and then immunohistochemically analyzed for tyrosine hydroxylase staining (TH) 21 days later **(A).** Treatment with MPTP and Vehicle (n=6) reduced the number of TH+ neurons in the substantia nigra **(B)** by approximately 50% (*, p=0.0002, Student's *t* test) relative to mice that received Vehicle only (n=8). MPTP-mediated cell death in the substantia nigra was significantly attenuated (**, p=0.005) in mice that additionally received P7C3A20 (10 mg/kg i.p. twice daily) (n=5). TH+ neurons in the substantia nigra of every mouse were counted blind to treatment group by two investigators using Image J software, and results were averaged.

Figure 26. Example 45 Compound (P7C3) Provides Therapeutic Benefit in Animal Model of Huntington's Disease. 40 female R6/2 mice were included in each of VEH (vehicle) and P7C3 (10 mg/kg P7C3 i.p. twice daily) groups, and treatment was begun at 6 weeks of age. **(A)** Treatment with P7C3 statistically significantly extends survival of R6/2 mice ($p<0.001$, Gehan-Breslow-Wilcoxon test). **(B)** At 14 weeks of age, P7C3-treated R6/2 mice also show statistically improved objective measures of general condition (lower score corresponds to better general better condition, * $p<0.0001$, Student's *t* Test). All measurements were conducted blind to genotype and treatment group.

Figure 27. Example 45 Compound (P7C3) Augments Hypothalamic Neurogenesis. Administration of P7C3 for a one month period of time augments proliferation of hypothalamic neural precursor cells (shown in red) in the arcuate nucleus (ARC), dorsomedial hypothalamus (DMH) and ventralmedial hypothalamus (VMH). Micrographs shown are representative of staining from every third section throughout the hypothalamus in 4-6 mice for each treatment group.

Compound Forms and Salts

The compounds of the presently disclosed embodiments may contain one or more asymmetric centers and thus occur as racemates and racemic mixtures, enantiomerically enriched mixtures, single enantiomers, individual diastereomers and diastereomeric mixtures. All such isomeric forms of these compounds are expressly included in the presently disclosed embodiments. The compounds of the presently disclosed embodiments may also contain linkages (e.g., carbon-carbon bonds, carbon-nitrogen bonds such as amide bonds) wherein bond rotation is restricted about that particular linkage, e.g. restriction resulting from the presence of a ring or double bond. Accordingly, all *cis/trans* and *E/Z* isomers and rotational isomers are expressly included in the presently disclosed embodiments. The compounds of the presently disclosed embodiments may also be represented in multiple tautomeric forms, in such instances, the presently disclosed embodiments expressly includes all tautomeric forms of the compounds described herein, even though only a single tautomeric form may be represented. All such isomeric forms of such compounds are expressly included in the presently disclosed embodiments.

Optical isomers can be obtained in pure form by standard procedures known to those skilled in the art, and include, but are not limited to, diastereomeric salt formation, kinetic resolution, and asymmetric synthesis. See, for example, Jacques, et al., Enantiomers, Racemates and Resolutions (Wiley Interscience, New York, 1981); Wilen, S.H., et al., Tetrahedron 33:2725 (1977); Eliel, E.L. Stereochemistry of Carbon Compounds (McGraw-Hill, NY, 1962); Wilen, S.H. Tables of Resolving Agents and Optical Resolutions p. 268 (E.L. Eliel, Ed., Univ. of Notre Dame Press, Notre Dame, IN 1972), each of which is incorporated herein by reference in their entireties. It is also understood that the presently disclosed embodiments encompass all possible regioisomers, and mixtures thereof, which can be obtained in pure form by standard separation procedures known to those skilled in the art, and include, but are not limited to, column chromatography, thin-layer chromatography, and high-performance liquid chromatography.

The compounds of the presently disclosed embodiments include the compounds themselves, as well as their salts and their prodrugs, if applicable. A salt, for example, can be formed between an anion and a positively charged substituent (e.g., amino) on a compound described herein. Suitable anions include chloride, bromide, iodide, sulfate, nitrate, phosphate, citrate, methanesulfonate, trifluoroacetate, and acetate. Likewise, a salt can also be formed between a cation and a negatively charged substituent (e.g., carboxylate) on a compound described herein. Suitable cations include sodium ion, potassium ion, magnesium ion, calcium ion, and an ammonium cation such as tetramethylammonium ion. Examples of prodrugs include C_{i_6} alkyl

esters of carboxylic acid groups, which, upon administration to a subject, are capable of providing active compounds.

Pharmaceutically acceptable salts of the compounds of the presently disclosed embodiments include those derived from pharmaceutically acceptable inorganic and organic acids and bases. As used herein, the term "pharmaceutically acceptable salt" refers to a salt formed by the addition of a pharmaceutically acceptable acid or base to a compound disclosed herein. As used herein, the phrase "pharmaceutically acceptable" refers to a substance that is acceptable for use in pharmaceutical applications from a toxicological perspective and does not adversely interact with the active ingredient.

Examples of suitable acid salts include acetate, adipate, alginate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, citrate, camphorate, camphorsulfonate, digluconate, dodecylsulfate, ethanesulfonate, formate, fumarate, glucoheptanoate, glycolate, hemisulfate, heptanoate, hexanoate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxyethanesulfonate, lactate, maleate, malonate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, nitrate, palmoate, pectinate, persulfate, 3-phenylpropionate, phosphate, picrate, pivalate, propionate, salicylate, succinate, sulfate, tartrate, thiocyanate, tosylate and undecanoate. Other acids, such as oxalic, while not in themselves pharmaceutically acceptable, may be employed in the preparation of salts useful as intermediates in obtaining the compounds of the presently disclosed embodiments and their pharmaceutically acceptable acid addition salts. Salts derived from appropriate bases include alkali metal (e.g., sodium), alkaline earth metal (e.g., magnesium), ammonium and N-$(alkyl)_4^+$ salts. The presently disclosed embodiments also envision the quaternization of any basic nitrogen-containing groups of the compounds disclosed herein. Water or oil-soluble or dispersible products may be obtained by such quaternization. Salt forms of the compounds of any of the formulae herein can be amino acid salts of carboxyl groups (e.g. L-arginine, -lysine, -histidine salts).

Lists of suitable salts are found in Remington's Pharmaceutical Sciences, 17th ed., Mack Publishing Company, Easton, Pa., 1985, p. 1418; Journal of Pharmaceutical Science, 66, 2 (1977); and "Pharmaceutical Salts: Properties, Selection, and Use A Handbook; Wermuth, C. G. and Stahl, P. H. (eds.) Verlag Helvetica Chimica Acta, Zurich, 2002 [ISBN 3-906390-26-8] each of which is incorporated herein by reference in their entireties.

The neutral forms of the compounds may be regenerated by contacting the salt with a base or acid and isolating the parent compound in the conventional manner. The parent form of the compound differs from the various salt forms in certain physical properties, such as solubility in polar solvents, but otherwise the salts are equivalent to the parent form of the compound for the purposes of the presently disclosed embodiments.

In addition to salt forms, the presently disclosed embodiments provide compounds which are in a prodrug form. Prodrugs of the compounds described herein are those compounds that undergo chemical changes under physiological conditions to provide the compounds of the presently disclosed embodiments. Additionally, prodrugs can be converted to the compounds of the presently disclosed embodiments by chemical or biochemical methods in an ex vivo environment. For example, prodrugs can be slowly converted to the compounds of the presently disclosed embodiments when placed in a transdermal patch reservoir with a suitable enzyme or chemical reagent. Prodrugs are often useful because, in some situations, they may be easier to administer than the parent drug. They may, for instance, be more bioavailable by oral administration than the parent drug. The prodrug may also have improved solubility in pharmacological compositions over the parent drug. A wide variety of prodrug derivatives are known in the art, such as those that rely on hydrolytic cleavage or oxidative activation of the prodrug. An example, without limitation, of a prodrug would be a compound of the presently disclosed embodiments which is administered as an ester (the "prodrug"), but then is metabolically hydrolyzed to the carboxylic acid, the active entity. Additional examples include peptidyl derivatives of a compound of the presently disclosed embodiments.

The presently disclosed embodiments also include various hydrate and solvate forms of the compounds.

The compounds of the presently disclosed embodiments may also contain unnatural proportions of atomic isotopes at one or more of the atoms that constitute such compounds. For example, the compounds may be radiolabeled with radioactive isotopes, such as for example tritium (^{3}H), iodine-125 (^{125}I) or carbon-14 (^{14}C). All isotopic variations of the compounds of the presently disclosed embodiments, whether radioactive or not, are intended to be encompassed within the scope of the presently disclosed embodiments.

SYNTHESIS

The compounds of the presently disclosed embodiments can be conveniently prepared in accordance with the procedures outlined in the Examples section, from commercially available starting materials, compounds known in the literature, or readily prepared intermediates, by employing standard synthetic methods and procedures known to those skilled in the art. Standard synthetic methods and procedures for the preparation of organic molecules and functional group transformations and manipulations can be readily obtained from the relevant scientific literature or from standard textbooks in the field. It will be appreciated that where typical or preferred process conditions (i.e., reaction temperatures, times, mole ratios of reactants, solvents, pressures, etc.) are

given, other process conditions can also be used unless otherwise stated. Optimum reaction conditions may vary with the particular reactants or solvent used, but such conditions can be determined by one skilled in the art by routine optimization procedures. Those skilled in the art of organic synthesis will recognize that the nature and order of the synthetic steps presented may be varied for the purpose of optimizing the formation of the compounds described herein.

Synthetic chemistry transformations (including protecting group methodologies) useful in synthesizing the compounds described herein are known in the art and include, for example, those such as described in R.C. Larock, *Comprehensive Organic Transformations,* 2d.ed., Wiley-VCH Publishers (1999); P.G.M. Wuts and T.W. Greene, *Protective Groups in Organic Synthesis,* 4th Ed., John Wiley and Sons (2007); L. Fieser and M. Fieser, *Fieser and Fieser's Reagents for Organic Synthesis,* John Wiley and Sons (1994); and L. Paquette, ed., *Encyclopedia of Reagents for Organic Synthesis,* John Wiley and Sons (1995), and subsequent editions thereof.

The processes described herein can be monitored according to any suitable method known in the art. For example, product formation can be monitored by spectroscopic means, such as nuclear magnetic resonance spectroscopy (e.g., ¾ or ^{13}C), infrared spectroscopy (FT-IR), spectrophotometry (e.g., UV-visible), or mass spectrometry (MS), or by chromatography such as high performance liquid chromatography (HPLC) or thin layer chromatography (TLC).

Preparation of compounds can involve the protection and deprotection of various chemical groups. The need for protection and deprotection, and the selection of appropriate protecting groups can be readily determined by one skilled in the art. The chemistry of protecting groups can be found, for example, in Greene, et al., *Protective Groups in Organic Synthesis,* 2d. Ed., Wiley & Sons, 1991, which is incorporated herein by reference in its entirety.

The reactions of the processes described herein can be carried out in suitable solvents which can be readily selected by one of skill in the art of organic synthesis. Suitable solvents can be substantially nonreactive with the starting materials (reactants), the intermediates, or products at the temperatures at which the reactions are carried out, i.e., temperatures which can range from the solvent's freezing temperature to the solvent's boiling temperature. A given reaction can be carried out in one solvent or a mixture of more than one solvents. Depending on the particular reaction step, suitable solvents for a particular reaction step can be selected.

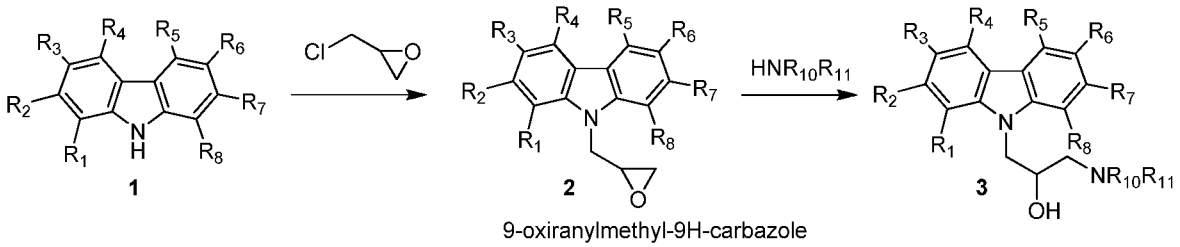
Resolution of racemic mixtures of compounds can be carried out by any of numerous methods known in the art. An example method includes preparation of the Mosher's ester or amide derivative of the corresponding alcohol or amine, respectively. The absolute configuration of the ester or amide is then determined by proton and/or ^{19}F NMR spectroscopy. An example method includes fractional recrystallization using a "chiral resolving acid" which is an optically active, salt-

forming organic acid. Suitable resolving agents for fractional recrystallization methods are, for example, optically active acids, such as the **D** and L forms of tartaric acid, diacetyltartaric acid, dibenzoyltartaric acid, mandelic acid, malic acid, lactic acid or the various optically active camphorsulfonic acids. Resolution of racemic mixtures can also be carried out by elution on a column packed with an optically active resolving agent (e.g., dinitrobenzoylphenylglycine). Suitable elution solvent compositions can be determined by one skilled in the art.

The compounds of the presently disclosed embodiments can be prepared, for example, using the reaction pathways and techniques as described below.

A series of carbazole 1,2-aminoalcohol compounds of formula **3** may be prepared by the method outlined in Scheme 1. The 9-oxiranylmethyl-9H-carbazole of formula **2** may be prepared from an appropriately substituted carbazole of formula **1** and epichlorohydrin in the presence of a strong base such as sodium hydride.

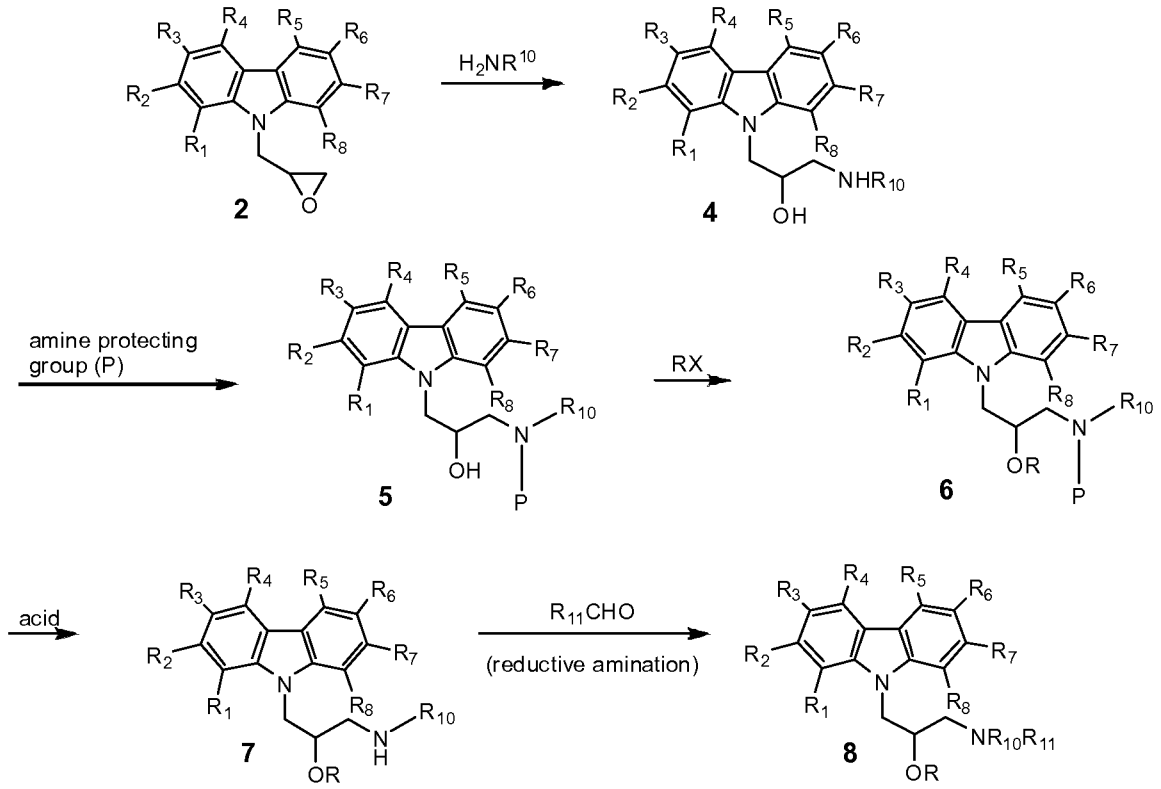
Scheme 1



The oxiranyl ring of formula **2** may be opened in the presence of a primary or secondary amine to produce the 1,2-amino alcohol of formula **3**. Such reactive primary or secondary amines can be, but are not limited to, phenethylamine, 3-phenylallyl amine, and N-substituted piperazines and the like.

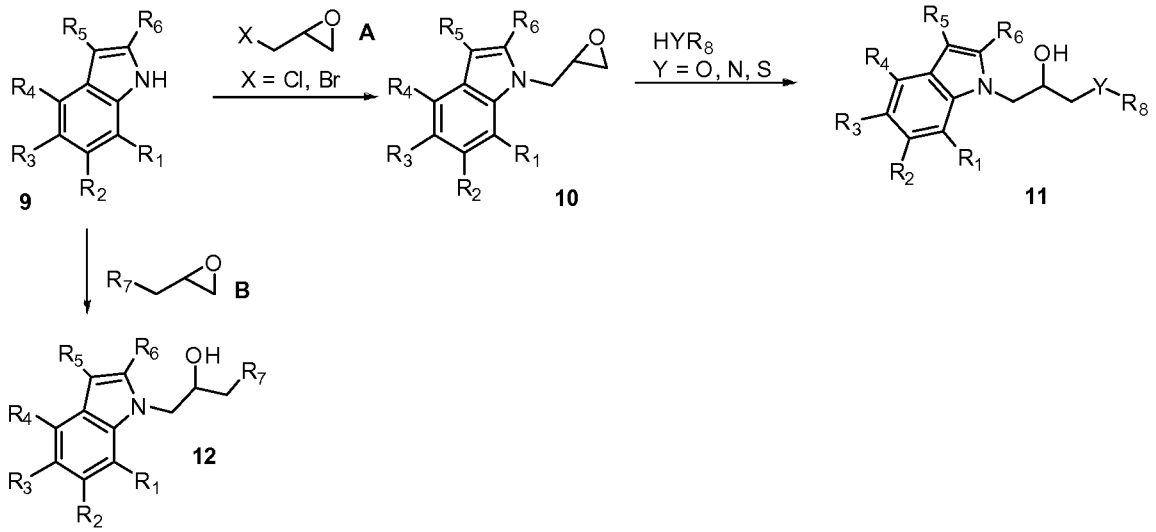
Alternatively, a variety of carbazole 1,2-aminoalcohol compounds of formula **8** may be prepared by the method outlined in Scheme 2. The epoxide of 9-oxiranylmethyl-9H-carbazole of formula **2** may be opened with a primary amine, ¾NR[10], to produce the secondary aminoalcohol of formula **4** and then protected with an amine protecting group (P) such as tert-butoxycarbonyl (Boc) to afford the protected aminoalochol of formula **5**. Next, the hydroxyl group of formula **5** may be alkylated with a strong base such as sodium hydride and an alkylating agent (RX) such as an alkyl halide, tosylate, triflate or mesylate to produce the ether of formula **6**. Removal of the amine protecting group in the presence of a suitable acid can provide the desired OR ether compounds of formula **7**. Finally, reductive alkylation of the secondary amine of formula **7** may be achieved in the presence of an aldehyde and a reducing agent such as sodium cyano borohydride ($NaCNBH_3$) to provide the tertiary 1,2-aminoalcohol of formula 8.

Scheme 2



A series of substituted indole compounds of formula **11** and **12** may be prepared by the method outlined below in Scheme 3. Compounds of formula **11** may be prepared by the alkylation of an indole of formula **9** with an epoxide A, for example with epichlorohydrin or epibromohydrin, in the presence of a strong base such as potassium hydroxide (KOH) or n-butyllithium (n-BuLi) to produce the oxiranyl indole of formula **10.** Next, opening of the epoxide of compounds of formula **10** with a primary amine, substituted alcohol or thiol in the presence of a strong base or a mild Lewis acid such as lithium bromide (LiBr) or bismuth chloride ($B1CI_3$) can provide the alcohol of formula **11.** Additionally, compounds of formula **12** may be prepared by opening an epoxide **B** at the less hindered position with the indole nitrogen of formula **9.**

Scheme 3



In addition, a variety of epoxide derivatives may be prepared by following the methods outlined in Scheme 4. The secondary alcohol of compounds of formula **11** may be oxidized using an oxidizing agent or under Swern-like oxidation conditions to provide the ketone of formula **13** which can further undergo reductive amination to provide the amine of compound **14.** Alternatively, the secondary alcohol may be converted into an ester using a carboxylic acid anhydride (where Z=R"C(0)) or an ether (where Z=alklyl) using standard alkylation conditions to produce compounds of formula **15.** Fluorine compounds of formula **16** may be prepared by reaction of the alcohol of formula **11** with a fluorinating agent such as diethylaminosulfur trifluoride (DAST). Nitrogen-heteroarylated compounds of formula **17** may be prepared in the presence of a catalytic amount of copper iodide and a heteroaryl iodide starting from compounds of formula **11** (where Y=N). Finally, sulfoxides and sulfones of formula **18** may be prepared under oxidative conditions, for example in the presence of m-chloroperoxybenzoic acid (m-CPBA), starting from sulfides of formula **11** (where Y=S).

PHARMACEUTICAL COMPOSITIONS

The term "pharmaceutically acceptable carrier" refers to a carrier or adjuvant that may be administered to a subject (e.g., a patient), together with a compound of the presently disclosed embodiments, and which does not destroy the pharmacological activity thereof and is nontoxic when administered in doses sufficient to deliver a therapeutic amount of the compound.

Pharmaceutically acceptable carriers, adjuvants and vehicles that may be used in the compositions of the presently disclosed embodiments include, but are not limited to, ion exchangers, alumina, aluminum stearate, lecithin, self-emulsifying drug delivery systems (SEDDS) such as d-a-tocopherol polyethyleneglycol 1000 succinate, surfactants used in pharmaceutical dosage forms such as Tweens or other similar polymeric delivery matrices, serum proteins, such as human serum albumin, buffer substances such as phosphates, glycine, sorbic acid, potassium sorbate, partial glyceride mixtures of saturated vegetable fatty acids, water, salts, or electrolytes,

such as protamine sulfate, disodium hydrogen phosphate, potassium hydrogen phosphate, sodium chloride, zinc salts, colloidal silica, magnesium trisilicate, polyvinyl pyrrolidone, cellulose-based substances, polyethylene glycol, sodium carboxymethylcellulose, polyacrylates, waxes, polyethylene-polyoxypropylene-block polymers, polyethylene glycol and wool fat. Cyclodextrins such as α-, β-, and γ-cyclodextrin, or chemically modified derivatives such as hydroxyalkylcyclodextrins, including 2- and 3-hydroxypropyl -P-cyclodextrins, or other solubilized derivatives may also be advantageously used to enhance delivery of compounds of the formulae described herein.

The compositions for administration can take the form of bulk liquid solutions or suspensions, or bulk powders. More commonly, however, the compositions are presented in unit dosage forms to facilitate accurate dosing. The term "unit dosage forms" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with a suitable pharmaceutical excipient. Typical unit dosage forms include prefilled, premeasured ampules or syringes of the liquid compositions or pills, tablets, capsules, losenges or the like in the case of solid compositions. In such compositions, the compound is usually a minor component (from about 0.1 to about 50% by weight or preferably from about 1 to about 40% by weight) with the remainder being various vehicles or carriers and processing aids helpful for forming the desired dosing form.

The amount administered depends on the compound formulation, route of administration, etc. and is generally empirically determined in routine trials, and variations will necessarily occur depending on the target, the host, and the route of administration, etc. Generally, the quantity of active compound in a unit dose of preparation may be varied or adjusted from about 1, 3, 10 or 30 to about 30, 100, 300 or 1000 mg, according to the particular application. In a particular embodiment, unit dosage forms are packaged in a multipack adapted for sequential use, such as blisterpack, comprising sheets of at least 6, 9 or 12 unit dosage forms. The actual dosage employed may be varied depending upon the requirements of the patient and the severity of the condition being treated. Determination of the proper dosage for a particular situation is within the skill of the art. Generally, treatment is initiated with smaller dosages which are less than the optimum dose of the compound. Thereafter, the dosage is increased by small amounts until the optimum effect under the circumstances is reached. For convenience, the total daily dosage may be divided and administered in portions during the day if desired.

The following are examples (Formulations 1-4) of capsule formulations.

Preparation of Solid Solution

Crystalline carbazole (80 g/batch) and the povidone (NF K29/32 at 160 g/batch) are dissolved in methylene chloride (5000 mL). The solution is dried using a suitable solvent spray dryer and the residue reduced to fine particles by grinding. The powder is then passed through a 30 mesh screen and confirmed to be amorphous by x-ray analysis.

The solid solution, silicon dioxide and magnesium stearate are mixed in a suitable mixer for 10 minutes. The mixture is compacted using a suitable roller compactor and milled using a suitable mill fitted with 30 mesh screen. Croscarmellose sodium, Pluronic F68 and silicon dioxide are added to the milled mixture and mixed further for 10 minutes. A premix is made with magnesium stearate and equal portions of the mixture. The premix is added to the remainder of the mixture, mixed for 5 minutes and the mixture encapsulated in hard shell gelatin capsule shells.

The compounds and compositions described herein can, for example, be administered orally, parenterally (e.g., subcutaneous ly, intracutaneously, intravenously, intramuscularly, intraarticularly, intraarterially, intrasynovially, intrasternally, intrathecally, intralesionally and by intracranial injection or infusion techniques), by inhalation spray, topically, rectally, nasally, buccally, vaginally, via an implanted reservoir, by injection, subdermally, intraperitoneally, transmucosally, or in an ophthalmic preparation, with a dosage ranging from about 0.01 mg/kg to about 1000 mg/kg, (e.g., from about 0.01 to about 100 mg/kg, from about 0.1 to about 100 mg/kg, from about 1 to about 100 mg/kg, from about 1 to about 10 mg/kg) every 4 to 120 hours, or according to the requirements of the particular drug. The interrelationship of dosages for animals and humans (based on milligrams per meter squared of body surface) is described by Freireich et al., Cancer Chemother. Rep. 50, 219 (1966). Body surface area may be approximately determined from height and weight of the patient. *See, e.g.,* Scientific Tables, Geigy Pharmaceuticals, Ardsley, New York, 537 (1970). In certain embodiments, the compositions are administered by oral administration or administration by injection. The methods herein contemplate administration of an effective amount of compound or compound composition to achieve the desired or stated effect. Typically, the pharmaceutical compositions of the presently disclosed embodiments will be administered from about 1 to about 6 times per day or alternatively, as a continuous infusion. Such administration can be used as a chronic or acute therapy.

Lower or higher doses than those recited above may be required. Specific dosage and treatment regimens for any particular patient will depend upon a variety of factors, including the activity of the specific compound employed, the age, body weight, general health status, sex, diet, time of administration, rate of excretion, drug combination, the severity and course of the disease, condition or symptoms, the patient's disposition to the disease, condition or symptoms, and the judgment of the treating physician.

Upon improvement of a patient's condition, a maintenance dose of a compound, composition or combination of the presently disclosed embodiments may be administered, if necessary. Subsequently, the dosage or frequency of administration, or both, may be reduced, as a function of the symptoms, to a level at which the improved condition is retained when the symptoms have been alleviated to the desired level. Patients may, however, require intermittent

treatment on a long-term basis upon any recurrence of disease symptoms.

In some embodiments, the compounds described herein can be coadministered with one or more other therapeutic agents. In certain embodiments, the additional agents may be administered separately, as part of a multiple dose regimen, from the compounds of the presently disclosed embodiments (e.g., sequentially, e.g., on different overlapping schedules with the administration of one or more compounds of formula (I) (including any subgenera or specific compounds thereof)). In other embodiments, these agents may be part of a single dosage form, mixed together with the compounds of the presently disclosed embodiments in a single composition. In still another embodiment, these agents can be given as a separate dose that is administered at about the same time that one or more compounds of formula (I) (including any subgenera or specific compounds thereof) are administered (e.g., simultaneously with the administration of one or more compounds of formula (I) (including any subgenera or specific compounds thereof)). When the compositions of the presently disclosed embodiments include a combination of a compound of the formulae described herein and one or more additional therapeutic or prophylactic agents, both the compound and the additional agent can be present at dosage levels of between about 1 to 100%, and more preferably between about 5 to 95% of the dosage normally administered in a monotherapy regimen.

The compositions of the presently disclosed embodiments may contain any conventional non-toxic pharmaceutically-acceptable carriers, adjuvants or vehicles. In some cases, the pH of the formulation may be adjusted with pharmaceutically acceptable acids, bases or buffers to enhance the stability of the formulated compound or its delivery form.

The compositions may be in the form of a sterile injectable preparation, for example, as a sterile injectable aqueous or oleaginous suspension. This suspension may be formulated according to techniques known in the art using suitable dispersing or wetting agents (such as, for example, Tween 80) and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are mannitol, water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. Fatty acids, such as oleic acid and its glyceride derivatives are useful in the preparation of injectables, as are natural pharmaceutically-acceptable oils, such as olive oil or castor oil, especially in their polyoxyethylated versions. These oil solutions or suspensions may also contain a long-chain alcohol diluent or dispersant, or carboxymethyl cellulose or similar dispersing agents which are commonly used in the formulation of pharmaceutically acceptable dosage forms such as emulsions

and or suspensions. Other commonly used surfactants such as Tweens or Spans and/or other similar emulsifying agents or bioavailability enhancers which are commonly used in the manufacture of pharmaceutically acceptable solid, liquid, or other dosage forms may also be used for the purposes of formulation.

The compositions of the presently disclosed embodiments may be orally administered in any orally acceptable dosage form including, but not limited to, capsules, tablets, emulsions and aqueous suspensions, dispersions and solutions. In the case of tablets for oral use, carriers which are commonly used include lactose and corn starch. Lubricating agents, such as magnesium stearate, are also typically added. For oral administration in a capsule form, useful diluents include lactose and dried corn starch. When aqueous suspensions and/or emulsions are administered orally, the active ingredient may be suspended or dissolved in an oily phase is combined with emulsifying and/or suspending agents. If desired, certain sweetening and/or flavoring and/or coloring agents may be added.

The compositions of the presently disclosed embodiments may also be administered in the form of suppositories for rectal administration. These compositions can be prepared by mixing a compound of the presently disclosed embodiments with a suitable non-irritating excipient which is solid at room temperature but liquid at the rectal temperature and therefore will melt in the rectum to release the active components. Such materials include, but are not limited to, cocoa butter, beeswax and polyethylene glycols.

Topical administration of the compositions of the presently disclosed embodiments is useful when the desired treatment involves areas or organs readily accessible by topical application. For application topically to the skin, the composition should be formulated with a suitable ointment containing the active components suspended or dissolved in a carrier. Carriers for topical administration of the compounds of the presently disclosed embodiments include, but are not limited to, mineral oil, liquid petroleum, white petroleum, propylene glycol, polyoxyethylene polyoxypropylene compound, emulsifying wax and water. Alternatively, the composition can be formulated with a suitable lotion or cream containing the active compound suspended or dissolved in a carrier with suitable emulsifying agents. Suitable carriers include, but are not limited to, mineral oil, sorbitan monostearate, polysorbate 60, cetyl esters wax, cetearyl alcohol, 2-octyldodecanol, benzyl alcohol and water. The compositions of the presently disclosed embodiments may also be topically applied to the lower intestinal tract by rectal suppository formulation or in a suitable enema formulation.

In some embodiments, topical administration of the compounds and compositions described herein may be presented in the form of an aerosol, a semi-solid pharmaceutical composition, a

powder, or a solution. By the term "a semi-solid composition" is meant an ointment, cream, salve, jelly, or other pharmaceutical composition of substantially similar consistency suitable for application to the skin. Examples of semi-solid compositions are given in Chapter 17 of The Theory and Practice of Industrial Pharmacy, Lachman, Lieberman and Kanig, published by Lea and Febiger (1970) and in Remington's Pharmaceutical Sciences, 21st Edition (2005) published by Mack Publishing Company, which is incorporated herein by reference in its entirety.

Topically-transdermal patches are also included in the presently disclosed embodiments. Also within the presently disclosed embodiments is a patch to deliver active chemotherapeutic combinations herein. A patch includes a material layer (e.g., polymeric, cloth, gauze, bandage) and the compound of the formulae herein as delineated herein. One side of the material layer can have a protective layer adhered to it to resist passage of the compounds or compositions. The patch can additionally include an adhesive to hold the patch in place on a subject. An adhesive is a composition, including those of either natural or synthetic origin, that when contacted with the skin of a subject, temporarily adheres to the skin. It can be water resistant. The adhesive can be placed on the patch to hold it in contact with the skin of the subject for an extended period of time. The adhesive can be made of a tackiness, or adhesive strength, such that it holds the device in place subject to incidental contact, however, upon an affirmative act (e.g., ripping, peeling, or other intentional removal) the adhesive gives way to the external pressure placed on the device or the adhesive itself, and allows for breaking of the adhesion contact. The adhesive can be pressure sensitive, that is, it can allow for positioning of the adhesive (and the device to be adhered to the skin) against the skin by the application of pressure (e.g., pushing, rubbing,) on the adhesive or device.

The compositions of the presently disclosed embodiments may be administered by nasal aerosol or inhalation. Such compositions are prepared according to techniques well-known in the art of pharmaceutical formulation and may be prepared as solutions in saline, employing benzyl alcohol or other suitable preservatives, absorption promoters to enhance bioavailability, fluorocarbons, and/or other solubilizing or dispersing agents known in the art.

A composition having the compound of the formulae herein and an additional agent (e.g., a therapeutic agent) can be administered using any of the routes of administration described herein. In some embodiments, a composition having the compound of the formulae herein and an additional agent (e.g., a therapeutic agent) can be administered using an implantable device. Implantable devices and related technology are known in the art and are useful as delivery systems where a continuous, or timed-release delivery of compounds or compositions delineated herein is desired. Additionally, the implantable device delivery system is useful for targeting specific points

of compound or composition delivery (e.g., localized sites, organs). Negrin et al., Biomaterials, 22(6):563 (2001). Timed-release technology involving alternate delivery methods can also be used in the presently disclosed embodiments. For example, timed-release formulations based on polymer technologies, sustained-release techniques and encapsulation techniques (e.g., polymeric, liposomal) can also be used for delivery of the compounds and compositions delineated herein.

The presently disclosed embodiments will be further described in the following examples. It should be understood that these examples are for illustrative purposes only and are not to be construed as limiting the presently disclosed embodiments in any manner.

To a solution of P7C3-S10 (20.0 mg, 0.0395 mmol, 1.0 equiv) in dichloromethane (790 μL) was added NaH (60% dispersion in mineral oil, 0.9 mg, 0.0395 mmol, 1.0 equiv). The mixture was stirred at room temperature for 15 minutes. (Sj-f+^-a-methoxy-a-trifluoromethyl-phenylacetyl chloride (14.8 μL, 0.0790 mmol, 2.0 equiv) was added dropwise into the reaction mixture. 4-(dimethylamino)pyridine (DMAP, catalytic) was added to the above mixture after 1 hour. The mixture was stirred at room temperature overnight and then quenched by water. The crude reaction was diluted with ethyl acetate and washed with brine. The organic layer was dried with $MgS0_4$ and concentrated to give crude product. It was further purified by silica gel preparative HPLC (20-25% EtOAc/Hex) to afford 10.1 mg white solid of the faster eluting diastereomer and 6.8 mg white as the slower eluting diasteromer, yield 59.2%. ^1H NMR ($CDC1_3$, 400 MHz) Faster eluting diasteromer: δ = 3.39 (s, 3H) 3.54 (s, 3H) 3.70 - 3.61 (m, 1H) 4.34 (dd, ***J*** = 30.0, 14.2 Hz, 1H) 4.61 - 4.44 (m, 2H) 5.24 (d, ***J*** = 50.4 Hz, 1H) 6.66 (d, ***J*** = 8.1 Hz, 1H) 7.40 - 7.23 (m, 10H) 7.54 (d, ***J*** = 8.6 Hz, 2H) 8.12 (s, 2H) Slower diastereomer: δ = 3.25 (s, 3H) 3.50 (s, 3H) 3.61 - 3.53 (m, 1H) 4.27 (dd, ***J*** = 32.4, 14.4 Hz, 1H) 4.61 - 4.40 (m, 2H) 5.32 (d, ***J*** = 50.3 Hz, 1H) 6.65 (d, ***J*** = 7.9 Hz, 1H) 7.42 - 7.20 (m, 10H) 7.56 (d, ***J*** = 8.6 Hz, 2H) 8.12 (s, 2H). P7C3-S113 (see below) was derived from the diastereomer that elutes faster on reverse phase HPLC (CI 8 column) and elutes slower by normal phase (silica gel) HPLC.

To dry and nitrogen flushed vials containing the separated products of Step 1 (4.0 mg, 0.00554 mmol, 1 equiv) was added anhydrous and degassed diethyl ether (206 μL). The suspension was chilled to 0°C. Lithium aluminum hydride solution (1M in THF, 60 μL, 0.06 mmol, 3 equiv) was added to the above chilled suspension. The mixture was stirred in ice bath for 1 hour and

further at room temperature for another 1 hour. Water (0.4 μL), 15% NaOH (0.4 μL) and water (1.2 μL) were added successively to the mixture to quench the reaction. The crude was diluted with ethyl acetate and washed with brine. The organic layer was dried with $MgSO_4$ and concentrated. It was further purified by silica gel chromatography (30% EtOAC/Hex) to afford 1.5 mg white solid as product, yield 50-55%. P7C3-S1 13 and -SI 14 displayed identical LC/MS chromtograms and NMR spectra as P7C3-S10. P7C3-S1 13 was found to have >99% ee by HPLC (Chiralcel OD-H, 1 mL/min, 100% Acetonitrile t_{sll3} = 5.45 min, t_{sll4} = 5.74 min). P7C3-S1 14 was found to have 79% ee.

It should be appreciated by one skilled in the art, as generally known, that different enantiomers may have different activity. One enantiomer can be more active than another enantiomer. Two enantiomers combined can have another level of activity that is different than either substantially pure enantiomer. Preliminary experiments suggest P7C3-S1 13 is more active than P7C3-S1 14 in pro-neurogenic and/or anti-apoptotic activities in an *in vivo* assay where 12 week old adult male C57/B16 mice were treated with 10 μM of either compound. It should be noted that such difference in enantiomer activity may also be observed in other compounds of the presently disclosed embodiments. It should also be noted that such activity may depend on assay mode, compound concentration, compound purity, compound stability, as well as other parameters. It is possible that when tested at a different concentration, a less active enantiomer may show increased activity, and vice versa.

Compounds were evaluated for pro-neurogenic efficacy / neuroprotection in our standard *in vivo* assay at 10 μM concentration in four 12 week old adult male C57/B16 mice.

The (+) *(dextrorotatory)* enantiomer of l-(3,6-Dibromo-9H-carbazol-9-yl)-3-(3-methoxyphenylamino)-propan-2-ol as described herein exhibited higher activity.

The (-) *(levorotatory)* enantiomer of l-(3,6-Dibromo-9H-carbazol-9-yl)-3-(3-methoxyphenylamino)-propan-2-ol as described herein exhibited lower activity.

Identification of pro-neurogenic or neuroprotective compounds:

In an effort to identify compounds that might stimulate the birth of new neurons, or protect newborn neurons from cell death, a library of 1,000 compounds was screened using an *in vivo* assay. In the initial screen, compounds were randomly pooled into groups often and administered intracerebroventricularly at a constant rate over seven days into the left lateral ventricle of living mice via Alzet osmotic mini-pumps. Compounds were administered at a concentration of 10μM for each molecule, making a total solute concentration of IOOμM. After seven days of infusion at a constant rate of 0.5μL/nour, a total of 84μL of volume will have left the pump (0.00084μMo 1es) and entered the cerebrospinal fluid. The average volume of a brain from a 12 week old male, C57/B6 mouse in our study is $500mm^3$. The maximal amount of drug was estimated that could potentially be present in the brain, taking the extreme and unlikely scenario of 100% absorbance of the drug into brain tissue and 0% clearance throughout the seven day infusion period. Under these conditions, at the end of one week of infusion each compound would be present at l^Molar concentration. Since the actual amount of chemical compound in the brain is likely to be only a fraction of this predicted level, it is reasonable to estimate that compounds were administered at mid to low-nanomolar concentrations.

During compound infusion, animals were intraperitoneally (IP) injected daily with the thymidine analog, bromodeoxyuridine (BrdU), as a means of scoring the birth and survival of proliferating neural precursor cells in the hippocampus. Because both social interaction and voluntary exercise are known to stimulate hippocampal neurogenesis, mice were housed individually without access to running wheels throughout the screening period. Following the week-long period of compound administration, animals were perfused and sacrificed. Dissected

brain tissue was fixed, embedded, sectioned, stained with antibodies to BrdU, and evaluated by light microcopy as a means of quantifying neurogenesis and survival of newborn neural precursor cells localized to the subgranular layer of the dentate gyrus on the brain hemisphere contralateral to the side of mini-pump cannulation. Every fifth section throughout the entire rostral-caudal extent of the hippocampus was analyzed, and the total number of BrdU+ cells was normalized against the measured volume of the dentate gyrus. Because both increased proliferation and survival of newborn neurons are important screening parameters, the screen was conducted over seven days in order to cast a wide net to detect molecules that might augment either process. The choice of parameters for the screen was based on pulse-chase experiments with a single injection of BrdU, under identical conditions to those used in our screen, which revealed that 40% of newborn cells in the dentate gyrus die within the first five days of their birth **(Figure 1).** Intracranial infusions of either fibroblast growth factor 2 (FGF-2) or artificial cerebral spinal fluid (aCSF) vehicle via the same, week-long protocol were employed as positive and negative controls. There was no difference in the number of BrdU-labeled cells in the dentate gyrus between mice subjected to surgical pump implantation and infusion with vehicle, and mice having had no surgery **(Figure 2).** This confirmed the validity of the *in vivo* approach to assess the ability of intracerebroventricularly infused compounds to enhance hippocampal neurogenesis in the contralateral hemisphere.

Considered to be important is that stimulation of neurogenesis triggered by any compound be localized to the exact region of the brain known to produce new neurons at an enhanced level in response to healthy activities such as wheel running, access to an enriched environment, or access to social interaction. For this reason attention was focused solely on compound pools that stimulated BrdU incorporation only in the subgranular zone of the dentate gyrus. Prominent nonspecific incorporation of BrdU in ectopic regions, such as CA3, CA1, cortex, or striatum, was presumed to reflect pathological inflammation, as proliferating cells incorporate BrdU in DNA synthesis, or to indicate other forms of toxicity, as cells also incorporate BrdU during DNA repair. Any compound pools yielding ectopic BrdU incorporation were eliminated from the screen. For an example, see **Figure 3.**

Each of the 100 pools was tested on two independent mice. As shown in **Figure 4,** ten of the 100 test pools were observed to enhance dentate gyrus-specific neurogenesis to an extent roughly equivalent to FGF-2. Each pool that scored positive in the initial two test animals was subsequently re-evaluated in two additional mice, and all ten pools were found to exert their pro-neurogenic effect with statistical significance **(Figure 5).** In order to identify single, pro-neurogenic compounds, positive pools were broken down into their ten component molecules, each of which was infused individually at two concentrations (10μM and IOOμM) in two mice per

concentration. **Figure 6A** shows the results of break-down assays on pool #7, wherein it was discovered that neurogenesis was selectively stimulated by one of the constituent chemicals of the pool (compound #3), chemicals in the pool demonstrating no effect. This molecule was designated as Example 45 Compound or P7C3. In breaking down the ten positive pools, eight pools yielded a single pro-neurogenic compound **(Figure 6B).** To ensure that the pro-proliferative or neuroprotective effect on neural stem cells was not an artifact of storage conditions in the UTSWMC chemical compound library, re-supplied compounds were verified to by 99% pure by mass spectrometry, evaluated in 4 mice each at 10 μM concentration, and shown to retain either pro-proliferative or neuroprotective properties in neural stem cells **(Figure 6C).**

Pharmacokinetic analysis of Example 45 Compound in plasma and whole brain tissue was undertaken after single IV, IP and oral gavage administrations. Example 45 Compound was noted to be orally bioavailable, readily able to cross the blood-brain barrier, and endowed with a plasma terminal half life of 6.7 hours after IP delivery. These favorable pharmacological properties facilitated a dose response experiment wherein daily oral administration of Example 45 Compound to adult mice was monitored for both brain levels of the chemical and pro-neurogenic efficacy **(Figure 7).** Maximal, pro-neurogenic efficacy was observed at oral doses of 5mg/kg and above, and graded reductions in efficacy were observed at doses of 2.5 and lmg/kg. Liquid chromatography-mass spectrometry analysis of the brain levels of Example 45 Compound in the dose ranges of 1, 2.5 and 5mg/kg revealed corresponding compound concentrations of 213 nM (lOlng/g brain tissue) , 1.13 μM (534ng/g brain tissue) and 1.35 μM (640ng/g brain tissue) five hours after dosing.

Enantiomer Selective Activity of Example 45 Compound Derivatives:

In order to further study Example 45 Compound, an *in vivo* structure activity relationship (SAR) study was conducted using 37 chemical derivatives of the compound for pro-neurogenic activity via direct administration into the brain of adult mice via Alzet minipumps. Compounds were administered for one week at lOuM into 4 mice per compound, along with daily IP injections of BrdU. Following compound administration, animals were perfused, sacrificed and subjected to sectioning, staining and light microscopy in order to monitor hippocampal neurogenesis localized to the subgranular layer of the dentate gyrus. Roughly 10% of the variant compounds retained pro-neurogenic activity indistinguishable from the parent compound. An approximately equal number of compounds yielded slightly diminished activity, yet the majority of variants were of significantly diminished activity **(Figure 8).** For example, a variant of Example 45 Compound having a methoxy substitution on the aniline ring (Example 62 Compound) was re-tested for pro-neurogenic

activity via direct administration into the brain of adult mice via Alzet minipumps. The compound was administered for one week at IOμM into 4 mice which were injected daily with BrdU. Following compound administration, animals were perfused, sacrificed and subjected to sectioning, staining and light microscopy in order to monitor hippocampal neurogenesis localized to the subgranular layer of the dentate gyrus. The methoxy derivative exhibited activity comparable to Example 45 Compound. Subsequently, the (+) and (-) enantiomers of Example 62 Compound were prepared **(Figure 9A).** The two enantiomers were evaluated in the *in vivo* neurogenesis assay. The (+)-enantiomer of Example 62 Compound retained potent pro-neurogenic activity, and the (-) enantiomer displayed diminished activity **(Figure 9B).** Other derivatives have also been resynthesized and retested, as described above.

Example 45 Compound Enhances the Survival of Newborn Neurons:

The nature of the cells produced in the subgranular zone of the dentate gyrus was investigated when Example 45 Compound was administered as follows. Animals were exposed to oral administration of Example 45 Compound for 30 days. Brain tissue was then prepared for immunohistochemical staining with an antibody to doublecortin (DCX), a microtubule-associated protein that serves as a marker of neurogenesis in the dentate gyrus by virtue of transient expression in newly formed neurons, but not glial cells, between the timing of their birth and final maturation (Brown et al., 2003). As shown in **Figure 10A,** the relative abundance of doublecortin-positive neurons increased dramatically as a function of exposure to prolonged administration of Example 45 Compound. Although this observation does not rule out the possibility that the compound might also enhance the formation of glial cells, it clearly shows that Example 45 Compound enhanced the formation of cells destined to become neurons.

Example 45 Compound-mediated neurogenesis was next investigated to see whether it was attributable to increased cell proliferation or protection of newborn cells from cell death during the time between their birth and eventual incorporation into the granular layer of the dentate gyrus. This was accomplished by comparing the ability of Example 45 Compound to enhance either short- or long-term increases in the incorporation of BrdU in the dentate gyrus **(Figure 10B).** Animals exposed to orally-delivered Example 45 Compound or vehicle for 30 days were administered a single pulse of BrdU via IP injection. Short-term effects on neuron birth were monitored by sacrificing animals one hour post-BrdU injection, followed by fixation of the tissue, sectioning and immunohistochemical detection of BrdU incorporation into cells localized in the subgranular layer of the dentate gyrus. Example 45 Compound administration did not lead to an elevation in the level of BrdU-positive cells relative to vehicle in this short-term assay. At one day after BrdU

administration both groups still showed no statistically significant differences in number of BrdU+ cells in the dentate gyrus. By contrast, at the 5 day time point, by which time 40% of newborn cells in our assay normally die **(Figure 1),** animals that received Example 45 Compound showed a statistically significant, 25% increase in BrdU+ cells compared to the vehicle-only control group. This difference between groups progressed with time such that mice that received a daily oral dose of Example 45 Compound for 30 days starting 24 hours after the pulse treatment of BrdU exhibited a 5-fold increase in the abundance of BrdU-positive cells in the dentate gyrus relative to vehicle-only controls. Notably, in this longer-term trial, BrdU-positive cells were observed not only along the subgranular layer of the dentate gyrus where new neurons are known to be born, but also within the granular layer itself. It is hypothesized that these cells represent mature neurons that have migrated into the granular layer, completed the differentiation process, and incorporated themselves into the dentate gyrus as properly wired neurons. Observations supportive of this interpretation will be presented in a subsequent section of this document. In summary, these experiments give evidence that Example 45 Compound enhances the formation of neurons in the mature hippocampus, and that its mode of action would appear to take place at some point subsequent to their birth.

It should be appreciated by one of ordinary skill in the art that the above described cell proliferation tests can also be used to test other compounds of presently disclosed embodiments.

Example 45 Compound Normalizes Apoptosis and Ameliorates Morphological and Electrophysiological Deficits in the Dentate Gyrus of NPAS3-Deficient Mice:

Mice lacking both copies of the gene encoding neuronal PAS domain protein 3 (NPAS3) suffer a profound impairment in adult neurogenesis (Pieper et al., Proc. Natl. Acad. Sci. USA 2005, 102, 14052-14057). By evaluating BrdU incorporation in a short-term assay of neurogenesis by sacrificing animals 1 hours after BrdU pulse, it was observed that NPAS3-deficient animals have no detectable deficit in the birth of neurons in the subgranular layer of the dentate gyrus **(Figure 11).** This is in contrast to our earlier observations of profoundly diminished BrdU labeling in the dentate gyrus of NPAS3-deficient animals when BrdU is administered for a longer period of time (12 days) (Pieper et al., Proc. Natl. Acad. Sci. USA 2005, 102, 14052-14057). Knowing that the NPAS3 transcription factor is required for proper expression of the fibroblast growth factor receptor 1 (FGFR1) in the hippocampus (Pieper et al., Proc. Natl. Acad. Sci. USA 2005, 102, 14052-14057), it is possible that impediments in growth factor signaling might impair the trophic environment critical for the survival of newborn neurons in the dentate gyrus. As an initial test of this hypothesis, brain tissue prepared from NPAS3-deficient animals was compared with that of wild

type littermates for the presence of cleaved caspase 3 (CCSP3)-positive cells in the subgranular layer of the dentate gyrus. A statistically significant, 2-fold increase in CCSP3-positive (apoptotic) cells was observed in the dentate gyrus of NPAS3-deficient animals **(Figure 11).** This enhanced rate of programmed cell death is likely to account, at least in part, for the nearly complete elimination of adult neurogenesis in mice lacking the NPAS3 transcription factor (Pieper et al., Proc. Natl. Acad. Sci. USA 2005, 102, 14052-14057).

In addition to this quantitative deficit in adult neurogenesis, abnormalities have been observed in both the morphology and electrophysiology of granular neurons of the dentate gyrus of NPAS3-deficient animals. Relative to wild type animals, Golgi-Cox staining revealed severe attenuation in dendritic branching and spine density of dentate gyrus granular neurons of NPAS3-deficient animals **(Figure 12A and 12B).** By contrast, no genotype-dependent differences in these measures were observed in pyramidal cells of the CA1 region of the hippocampus. Equivalently specific deficits were observed by electrophysiologic recordings of NPAS3-deficient animals compared with wild type littermates **(Figure 13A and 13B).** Whole field recordings of excitatory postsynaptic potentials (fEPSP) revealed significant deficits in NPAS3-deficient animals, relative to wild type littermates. In the dentate gyrus, stimulating and recording electrodes were positioned in the outer molecular layer, which is innervated by axons of the perforant pathway originating from the entorhinal cortex. In the CA1 region of the hippocampus, stimulation and recording electrodes were positioned in the stratum radiatum, which is innervated by the Schaffer collateral axons of CA3 pyramidal cells. Stimulus intensity was increased in 5 μA increments, the slope of the decreasing part of field potentials was measured, and fEPSP was quantified relative to the amplitude of the fiber volley, which represents firing of action potentials in pre-synaptic axons. This analysis revealed aberrant hyper-excitability of synaptic transmission in *npas3*$^{-/-}$ mice both in the outer molecular layer of the dentate gyrus and in the CA1 region **(Figure 13A and 13B).**

Armed with these genotype- and region-specific deficits in both neuron morphology and electrophysiological activity, whether prolonged administration of Example 45 Compound might favorably repair either deficit in NPAS3-deficient animals was tested. Before embarking on this effort, it was first confirmed that Example 45 Compound was capable of enhancing hippocampal neurogenesis in NPAS3-deficient mice, by demonstrating that Example 45 Compound enhances both BrdU incorporation as well as expression of doublecortin in newborn neurons in the dentate gyrus of *npas3*$^{-/-}$ mice **(Figure 14).** Knowing that formation of the dentate gyrus initiates in the late pre-natal mouse embryo around embryonic day 14 (Stanfield and Cowan, 1988, The development of the hippocampal region. In Cerebral Cortex, E.G. Jones and A. Peters, eds. (New York: Plenum Press), pp. 91-131), animals were exposed to Example 45 Compound for as extended a period of

time as possible in order to give the compound the best possible chance for exhibiting favorable effects. Following oral gavage of pregnant female mice, 14 day embryos were recovered, dissected and processed by acetonitrile:water extraction so that Example 45 Compound levels could be measured in the embryonic brain. Daily administration of 20mg/kg of Example 45 Compound to pregnant females yielded appreciable levels of the compound in the brain tissue of developing embryos. It was similarly observed that oral administration of the compound to lactating females led to delivery of Example 45 Compound to the brain tissue of weanling pups. In both cases, LC/MS-based quantitation of Example 45 Compound revealed levels of compound accumulation at or above the 1.35μM limit required to support adult neurogenesis **(Figure 7).** Finally, it was observed that daily IP administration of Example 45 Compound to weaned pups at 20 mg/kg was sufficient to yield brain levels of Example 45 Compound at or above the level required to enhance adult neurogenesis.

Female mice heterozygous at the NPAS3 locus were mated to heterozygous males. Two weeks post-mating, females were given a daily oral gavage of either 20mg/kg of Example 45 Compound or vehicle-only formula. Dosing was continued throughout the last trimester of pregnancy, as well as the two week post-natal period of lactation. Following weaning, pups were given a daily IP dose of either 20 mg/kg Example 45 Compound or vehicle control. At about 7 weeks of age, mice were switched to oral gavage delivery of the same dose of Example 45 Compound. When mice were 3 months of age they were sacrificed and brain tissue was dissected and subjected to either Golgi-Cox staining or electrophysiological recording. As shown in **Figure 15,** prolonged exposure to Example 45 Compound robustly repaired morphological deficits in the dendritic branching of granular neurons of the dentate gyrus in NPAS3-deficient mice. Moreover, as shown in **Figure 13A,** the electrophysiological deficit in the dentate gyrus of NPAS3-deficient mice was also corrected following prolonged exposure of mice to Example 45 Compound. The corresponding electrophysiological deficit in CA1 region of the hippocampus, however, was not affected **(Figure 13B),** underscoring the specificity of Example 45 Compound to improving functioning of the dentate gyrus in this animal model.

It is also notable that, relative to vehicle-only controls, administration of Example 45 Compound did not affect any aspect of the health of mothers, embryos, weanlings or young adult mice. Gross histology of brain tissue was normal in both compound- and vehicle-treated animals, and there was no evidence of neuronal cell loss or degenerative changes (cytoplasmic eosinophilia, vacuolization or nuclear pyknosis). The only morphological change, other than normalization of dendritic arborization of granular neurons of the dentate gyrus, was a compound-dependent increase in the thickness of the granular layer of the dentate gyrus itself **(Figure 16).** The thickness

of the granular layer of the dentate gyrus is roughly 40% less in NPAS3 -deficient animals than wild type littermates. Prolonged administration of Example 45 Compound through late embryonic development, early post-natal development, and two months post-weaning significantly corrected this deficit without affecting the thickness of other hippocampal layers in NPAS3 -deficient mice **(Figure 16).**

Recognizing that the reduced thickness of the granular layer of the dentate gyrus in NPAS3-deficient animals could be attributed to elevated levels of apoptosis of newborn hippocampal neural precursor cells, the effect of Example 45 Compound treatment on apoptosis in the hippocampus of NPAS3 -deficient animals was examined through immunohistochemical staining of cleaved caspase 3 (CCSP3). As shown in **Figure 17,** 12 days of treatment with orally delivered Example 45 Compound (20 mg/kg) to adult NPAS3 -deficient animals significantly reduced CCSP3 staining in the dentate gyrus, whereas vehicle-treatment had not effect. It is thereby proposed that Example 45 Compound facilitated repair of the granular layer of the dentate gyrus in NPAS3 -deficient mice by ameliorating a genotype-specific exacerbation of programmed cell death.

It should be appreciated by one of ordinary skill in the art that the above described apoptosis tests can also be used to test other compounds of presently disclosed embodiments.

Example 45 Compound Protects Mitochondrial Integrity:

Extensive evidence pioneered by the laboratory of Xiaodong Wang has shown that an intrinsic pathway leading to programmed cell death emanates from mitochondria (Liu et al., Cell 1996, 86, 147-157; Yang et al., Science 1997, 275, 1129-1132). With the help of the Wang lab, assays were established to test whether Example 45 Compound might protect mitochondria from calcium-induced dissolution (Distelmaier et al., Cytometry A 2008, 73, 129-138). Tetramethylrhodamine methyl ester (TMRM) is a cell-permeant, cationic red-orange fluorescent dye that is readily sequestered by active mitochondria. When loaded with TMRM dye, vehicle-only treated cells released the dye within 15 minutes of exposure to the calcium ionophore A23 187. By contrast, dye release was prevented in cells exposed to as little as lOng of Example 45 Compound **(Figure 18A).** As with *in vivo* neurogenesis assay, as well as the *in vitro* protection from $A\beta_{(25-35)}$-mediated toxicity of cultured cortical neurons, preservation of mitochondrial membrane potential in this assay was observed only with the (+) enantiomer of Example 62 Compound **(Figure 18B).**

It should be appreciated by one of ordinary skill in the art that the above described mitochondrial integrity tests can also be used to test other compounds of presently disclosed embodiments.

Comparison of Example 45 Compound and Dimebon:

A chemical compound sharing structural similarity to Example 45 Compound is 2,3,4,5-Tetrahydro-2,8-dimethyl-5-(2-(6-methyl-3-pyridyl)ethyl)-lH-pyrido(4,3-b)indole **(Figure 19A).** An anti-histamine, trade named Dimebon, was anecdotally noticed over the decades to ameliorate symptoms of dementia (O'Brien, Lancet Neurol. 2008, 7, 768-769; Burns and Jacoby, Lancet 2008, 372, 179-180). More recently, an American biotechnology company designated Medivation initiated clinical trials to formally test whether Dimebon might improve the symptoms of patients suffering from Alzheimer's disease. The results of FDA-sponsored, phase 2 clinical trials in Alzheimer's disease were recently published, reporting favorable response rates (Doody et al., Lancet 2008, 372, 207-215). Example 45 Compound and Dimebon were compared in three functional assays. The *in vivo* test for effects on hippocampal neurogenesis revealed activity for both compounds, with Example 45 Compound exhibiting between 10- and 30-fold higher level of potency and a ceiling of efficacy roughly 40% higher than the anti-histamine drug **(Figure 19B).** Dimebon has been implicated in protecting mitochondria (Bachurin et al., Ann. NY Acad. Sci. 2001, 939, 425-435; Bachurin et al., Ann. NY Acad. Sci. 2003, 993, 334-344, discussion 345-349). Therefore Dimebon was compared with Example 45 Compound in the calcium-induced mitochondrial dissolution assay. Both compounds were observed to be active, and it was again observed that the relative potency of Example 45 Compound was superior to Dimebon **(Figure 19C).** Protection of mitochondrial membrane permeability was lost for Example 45 Compound between the 10 and InM doses, whereas that of Dimebon was lost between 10 and IμM.

Example 45 Compound and Dimebon were tested for binding to the HI histamine receptor. While Dimebon displayed high affinity for this receptor (IC50 < 100 nM), both enantiomers of Example 45 Compound display low HI affinity (IC50 > 10 μM).

It should be appreciated by one of ordinary skill in the art that the above described binding activity tests can also be used to test other compounds of presently disclosed embodiments.

Effect of Example 45 Compound on Aged Rats

Next, aged Fisher rats were used as a means of performing behavioral tests capable of assessing the potential benefits of Example 45 Compound on hippocampus-dependent learning. It is well established that normal rodent aging is associated with attenuation of hippocampal neurogenesis (Kuhn et al., J. Neurosci. 1996, 16, 2027-2033; Driscoll et al., Neuroscience 2006, 139, 1173-1 185). Reduced neurogenesis in aged rats is likely related to increased neuronal apoptosis in the aged rat brain (Martin et al., J. Biol. Chem. 2002, 277, 34239-34246; Kim et al.,

Exp. Gerontol. 2010, 45, 357-365). These changes have been hypothesized to contribute to cognitive decline as a function of terminal aging.

It was first evaluated whether Example 45 Compound would enhance hippocampal neurogenesis in aged rats as it does in adult mice. Rats were injected with a daily, IP dose of either 10 mg/kg of Example 45 Compound or vehicle, coinjected with a daily dose of BrdU, and then sacrificed after 7 days for immunohistochemistry. As shown in **Figure 20A,** compound-treated animals revealed a 500% increase in BrdU labeling in the dentate gyrus relative to vehicle-treated controls. Immunohistochemical staining with antibodies to doublecortin likewise revealed a robust, compound-specific enrichment in this marker of newborn neurons. Having observed proneurogenic efficacy of Example 45 Compound in this short term assay, it was then tested whether prolonged administration of Example 45 Compound might ameliorate age-related decline in cognition by subjecting 18-month-old rats to daily administration of either i 0 mg/kg of Example 45 Compound or vehicle only for 2 months. Animals of both groups were further subjected to weekly IP administration of BrdU (50 mg/kg) for later immunohistochemical measurements of hippocampal neurogenesis. As a control, both Example 45 Compound- and vehicle-treated groups were confirmed to display equal ability to physically participate in the task, and learn the task, as shown by decreased latency times to find the hidden platform over the 5 day training period, both before and after 2 months of treatment **(Figure 20B).** Moreover, neither swim speed **(Figure 20C)** nor locomotor activity **(Figure 20D)** varied with age or treatment paradigm.

After 2 months of compound or vehicle administration, cognitive ability was assessed blind to treatment group by removing the goal platform. Animals of the Example 45 Compound-treated group retained a statistically significant improvement in ability to navigate to the region of the missing platform, as evidenced by performance in the probe test. As shown in **Figure 21**A, when the platform was removed from the maze, rats treated with Example 45 Compound crossed the precise location previously containing the platform significantly more often than vehicle-treated rats. Furthermore, Example 45 Compound-treated rats spent a higher percentage of time in the general goal area, defined as the quadrant previously containing the platform, than vehicle-treated rats (35.5% $\pm$ 2.2% for Example 45 Compound treated, 28. 1% ± 2.6% for vehicle treated, Student's t Test, $p < 0.02$).

After behavioral testing, animals were sacrificed for immunohistochemical detection of BrdU and CCSP3. As shown in **Figure 21B,** the dentate gyrus of rats exposed to Example 45 Compound showed a 3-fold higher level of BrdU-positive neurons than that of the vehicle group. Moreover, Example 45 Compound-treated animals showed a statistically significant reduction in the number of CCSP3-positive cells relative to vehicle controls **(Figure 21C).** Unexpectedly, administration of Example 45 Compound helped rats maintain stable body weight with aging, in

contrast to vehicle-treated rats, whose weight declined steadily with age **(Figure 21D).** Example 45 Compound-mediated effects on body weight were independent of food intake **(Figure 20E),** and treatment of aged rats with Example 45 Compound had no effect on postfasting blood glucose levels (Figure 20E). Next it was tested whether Example 45 Compound-mediated preservation of body weight in aged rats operates via central or peripheral modes of action.

It should be appreciated by one of ordinary skill in the art that the above described in vivo tests in rats or other animal models can also be used to test other compounds of presently disclosed embodiments.

Example 45 Compound Augments Hypothalamic Neurogenesis

Positioned immediately below the thalamus and forming the floor and lower lateral walls of the third ventricle, the hypothalamus consists of multiple groups of cells that regulate the autonomic nervous system and also control motivational behaviors via extensive neuronal connections to the pituitary gland, thalamus, midbrain and cerebral cortex. These functions include water balance, biological rhythms, feeding and drinking drive, sexual activity, pituitary gland function and temperature regulation. Neural stem cells in the adult brain reside in the wall of the third ventricle and proliferate in response to various stimuli, and formation of new neurons in the hypothalamus has also been observed in the hypothalamic parenchyma. Administration of trophic factors such as brain-derived neurotrophic factor and ciliary neurotrophic factor enhances neurogenesis in the rodent hypothalamus. Furthermore, newborn neurons in the adult hypothalamus integrate into existing hypothalamic neural circuits and express neuronal markers such as POMC (phosphorylated signal transducer of activator of transcription), neuropeptide Y, ocytocin and vasopressin. During hypothalamic development, POMC-expressing progenitor cells differentiate into two populations of cells with antagonistic roles, expressing either POMC or neuropeptide Y, that exert opposite effects in regulating energy balance. It is thus proposed that differential regulation of postnatally-generated neurons in the hypothalamus might form the basis of developing new treatments to regulate food intake behavior. This hypothesis is supported by observations that acute ablation of new hypothalamic neurons leads to severe anorexia and weight loss.

It was evaluated whether P7C3 might augment hypothalamic neurogenesis by administering either vehicle or P7C3 (10 mg/kg twice daily, i.p.) to nine week old male C57BL/6 mice, starting two days before implantation of 7 day Alzet osmotic minipumps (model 1007d) loaded with BrdU (lmg/kg). Pumps were connected to a cannula that delivered BrdU at a constant rate into the left lateral ventricle for the seven day period, during which time animals continued to receive either

vehicle or P7C3. Pumps were surgically removed at the conclusion of their 7 day operating period, and mice were allowed to survive for 4 more weeks, during which time they continued to receive either vehicle or P7C3. At the end of the 4 week period, mice were deeply anesthetized with intraperitoneal (i.p.) injection of mouse anesthetic cocktail and transcardially perfused with 4% paraformaldehyde (PFA) in phosphate buffered saline (pH 7.4). Brains were then dissected and post-fixed overnight at 4 degrees Celsius in 4% PFA, and cryoprotected in 30 % sucrose in PBS. Fixed brains were embedded in O.C.T and cut at 20 micrometer thickness with a cryostat. Every third section was immunohistochemically stained for BrdU (Accurate, rat anti-Brdu ,1:400) per our standard procedures. Anti-rat Dylight 596 was used to visualize BrdU incorporation. As can be seen from **Figure 27,** treatment with P7C3 markedly enhances hypothalamic neurogenesis in the rodent brain, with a significantly increased amount of BrdU positive staining.

It should be appreciated by one of ordinary skill in the art that the above described hypothalamic neurogenesis tests can also be used to test other compounds of presently disclosed embodiments.

Because P7C3 (and its derivatives and analogs) can enhance hypothalamic neurogenesis, compounds of the presently disclosed embodiments can be useful for regulating hypothalamic functions such as water balance, biological rhythms, feeding and drinking drive, sexual activity, pituitary gland function and temperature regulation. For example, given P7C3's role in maintaining stable body weight in aging rats, compounds of the presently disclosed embodiments can provide therapeutic benefits to patients experiencing physiological weight loss for various reasons, such as normal aging, radiation treatment, chemotherapy, anorexia, cachexia, diabetes, stress, substance abuse, dementia, stroke, cancer, infection, as well as other diseases and/or conditions.

Example 45 Compound Protects Mitochondria

Since P7C3 ameliorates the death of newborn neurons in the dentate gyrus in living mice, it is possible that its function might relate to mitochondrial integrity. Assays were established to test whether P7C3 might protect cultured U20S cells from calcium-induced mitochondrial dissolution (Distelmaier et al., Cytometry A 2008, 73, 129-138). Tetramethylrhodamine methylester (TMRM) dye is sequestered by active mitochondria, and, when loaded with TMRM, vehicle-treated cells released the dye within 15 rain of exposure to the calcium ionophor A23 187. By contrast, dye release was fully prevented in cells exposed to as little as IOηM of P7C3 **(Figure *22A).*** Compounds known to be less active in vivo were also less active in this assay (not shown). Preservation of mitochondrial membrane potential in this assay was observed for the R-enantiomer of P7C3-OMe, Example lb, **(Figure 22B),** but not the S-enantiomer, Example la, **(Figure 22C).** Finally, protection of mitochondrial membrane permeability was observed at an enhanced level for

a compound variant P7C3A20 (Example 6a), which also exhibited a high level of proneurogenic activity **(Figure 22D).** Derivatives that have less proneurogenic activity than P7C3 such as Example 33 **(Figure 22E)** and Example 21 **(Figure 22F),** displayed less protective effect in preserving mitochondrial integrity at the tested doses in cultured primary cortical neurons.

It was also examined whether Example 45 Compound preserves mitochondrial membrane potential in cultured primary cortical neurons **(Figure 23).** Cortical neurons cultures from rats on embryonic day 14 were loaded with tetramethylrhodamine methyl ester (TMRM) dye after 6 days of maturation. The top panels (no calcium ionophore) show that the dye alone did not affect the health of neurons. The remaining panels are from cells that were exposed to the calcium ionophore A23187 at time zero. With vehicle-alone, cortical neuron mitochondrial membrane potential was rapidly lost after exposure to the ionophore. Escalating doses of Example 45 Compound preserved mitochondrial membrane potential following exposure to the calcium ionophore A23187 in a dose dependent manner, with full protection achieved at 1 mM. The less active compound (Example 33) was less effective in preserving mitochondrial membrane potential at any dose tested. Results shown are representative of 10 fields analyzed in each of 2 experimental runs for all conditions.

It should be appreciated by one of ordinary skill in the art that the above described mitochondrial tests can also be used to test other compounds of presently disclosed embodiments.

Example 45 Compound Normalizes Elevated Levels of Hippocampal Apoptosis in *npas3* $^{-/-}$ Mice

Recognizing that reduced thickness of the *npas3* $^{-/-}$ dentate gyrus granular layer could be attributed to increased apoptosis of proliferating neural precursor cells, the effect of Example 45 Compound (P7C3) treatment on apoptosis in the hippocampus of *npas3* $^{-/-}$ mice was examined through immunohistochemical staining of CCSP3. As shown in **Figure 17,** after 12 days of orally delivered Example 45 Compound (20 mg/kg) to adult npas3-/- mice, a statistically significant reduction in CCSP3 staining was observed in the dentate gyrus. It is thereby proposed that Example 45 Compound facilitates repair of the granular layer of the dentate gyrus in npas3 $^{-/-}$ mice by overcoming a genotype-specific enhancement in apoptosis.

It should be appreciated by one of ordinary skill in the art that the above described mice model and other animal model can also be used to test other compounds of presently disclosed embodiments.

Example 45 Compound (P7C3) Provides Therapeutic Benefit in Animal Model of Amyotrophic Lateral Sclerosis (ALS)

ALS, also known as Lou Gehrig's disease, is an adult-onset (typically between ages 40-70), rapidly progressive and fatal disease caused by selective degeneration of upper (cortical layer V within the primary motor cortex) and lower (spinal cord) motor neurons, the nerve cells in the central nervous system that control voluntary muscle movement. An estimated 5000 people in the United States are diagnosed with ALS every year. This disorder causes muscle weakness and atrophy throughout the body, and patients with ALS ultimately lose their ability to initiate and control all voluntary movement. The earliest parts of the body affected in ALS reflect those motor neurons that are damaged first. About 75% of patients experience onset of symptoms in their arms or legs manifested as difficulty with manual dexterity or ambulation, while about 25% experience 'bulbar onset' of ALS - difficulty speaking clearly or swallowing. A small proportion of patients have respiratory onset of ALS in the form of weakness of the intercostal muscles that support breathing. Regardless of the region of onset, muscle weakness and atrophy invariably spread to other parts of the body as the disease progresses. Most patients develop a constellation of symptoms that includes difficulty moving, dysphagia (difficulty swallowing), dysarthria (difficulty speaking or forming words) and classical manifestations of loss of upper motor neurons (muscular spasticity, hyperreflexia and overactive gag reflex) and lower motor neurons (muscular weakness, muscle atrophy, muscle cramps and fasciculations). Sensory nerves and the autonomic nervous system are usually spared, though may be involved in some patients. About 20% of ALS patients also develop frontotemporal lobar dementia (FTLD), while 30-50% of patients develop subtle cognitive changes that can be observed with detailed neuropsychological testing. Around 15-45% of patients with ALS also experience what is called "pseudobulbar affect" - a form of emotional lability in which patients manifest intermittent bouts of uncontrollable laughter, crying or smiling. This symptom domain is thought to be related to degeneration of bulbar upper motor neurons, resulting in exaggerated motor expressions of emotion. Although disease progression varies between individuals, most patients are eventually unable to stand or walk, get in or out of bed on their own, or use their hands and arms. Difficulty chewing and swallowing further leads to progressive weight loss and increased risk of choking and aspiration pneumonia. Towards the end stages of disease, as the diaphragm and intercostal muscles weaken, most patients require ventilator support. Individuals with ALS most commonly die of respiratory failure or pneumonia within 2-5 years of diagnosis.

Ninety-five percent of ALS cases occur sporadically (SALS), with no identifiable cause or family history of the disease. The remaining 5% of cases are inherited, known as Familial ALS (FALS). Because FALS and SALS are clinically and neuropathologically similar, the pathogenesis of these forms of ALS may converge on a common pathogenic pathway. Approximately 20% of

FALS and 3% of SALS cases are associated with autosomal dominant mutations in the *SOD1* gene on chromosome 21, and about 150 different mutations dispersed throughout this gene have been identified in FALS. *SOD1* encodes cytosolic Cu/Zn superoxide dismutase, an antioxidant enzyme that protects cells by converting superoxide (a toxic free radical generated through normal metabolic activity of mitochondria) to hydrogen peroxide. Unchecked, free radicals accumulate and damage both mitochondrial and nuclear DNA, as well as proteins within cells. In ALS linked to mutations in *SOD1,* cytotoxicity of motor neurons appears to result from a gain of toxic SOD1 function, rather than from loss of dismutase activity. Although the exact molecular mechanisms underlying toxicity are unclear, mutation-induced conformational changes in SOD 1 are known to lead to misfolding and subsequent cytotoxic aggregation of mutant SOD1 in cell bodies and axons. Aggregate accumulation of mutant SOD 1 is thought to disrupt cellular functions and precipitate neuron death by damaging mitochondria, proteasomes, protein folding chaperones, or other proteins.

Transgenic animal models of mutant SOD1 are currently used for research into the pathogenic mechanisms thought to broadly underlie ALS, such as G93A SOD1 mutant mice. Mice hemizygous for the G93A-SOD1 transgene express 18 +/- 2.6 copies of a form of *SOD1* found in some patients with FALS (a substitution of glycine to alanine at codon 93). This was the first mutant form *oiSOD1* to be expressed in mice, and is the most widely used and well-characterized mouse model of ALS. Superoxide dismutase activity in these mice is left intact such that the pathogenic effect of the mutant transgene appears to be gain of function, as is thought to occur in human patients. In these mice, death of motor neurons in the ventral horn of the spinal cord and loss of myelinated axons in ventral motor roots leads to paralysis and muscle atrophy. Upper cortical motor neurons in these mice also die as the disease progresses, and protein aggregates of mutant SOD1 are found only in diseased tissues, with greater amounts being detected during motor neuron degeneration. Around 100 days of age, G93A-SOD1 mice become paralyzed in one or more limbs with paralysis due to loss of motor neurons from the spinal cord. This paralysis rapidly spreads throughout the body, culminating in 50% death when mice are 128.9 +/- 9.1 days old.

P7C3 was intraperitoneally administered to female G93A-SOD1 transgenic mice using a treatment paradigm of 10 mg/kg P7C3 i.p. twice a day, compared to vehicle, starting at 40 days of age. This treatment scheme was selected based on standard protocols for initial proof of concept screens in these mice. To control for transgene copy number, mice are sibling matched between treatment groups, as per standard protocol. After initiation of P7C3 or vehicle treatment, date of onset of illness is determined by peak weight, and initial progression of disease is defined as the day at which mice fall to 10% below their maximum weight. Mice are also assessed daily by a

standard determination of neurological severity score, with a score of 2 or worse for two consecutive days serving as an additional marker of illness progression. This score is determined blind to treatment group with the scoring system described in the legend for the figure. As shown in **Figure 24A,** P7C3 treatment slows disease progression in G93A-SOD1 mice in terms of delaying the time point at which mice drop to 10% below their maximum weight. Treatment with P7C3 also significantly delays the age at which G93A-SOD1 mice attain a neurological severity score of 2, another marker of disease progression, as shown in **Figure 24B.** Furthermore, P7C3 treatment significantly improved performance in the accelerating rotarod task as the disease progressed in these mice, as shown in **Figure 24C,** indicating a slowing of progression of motor impairment in the disease process. This protective effective of P7C3 on motor performance in G93A-SOD1 mice is also observed in the ink footprint analysis of walking gait, as shown in **Figure 24D.**

It should be appreciated by one of ordinary skill in the art that the above described ALS model and other animal model can also be used to test other compounds of presently disclosed embodiments.

Example 6a Compound (P7C3A20) Provides Therapeutic Benefit in Animal Model of Parkinson's Disease

Parkinson's disease (PD) is a progressive neurodegenerative disease characterized by the death of dopaminergic neurons in the substantia nigra, which project to the striatum to control normal movement. Though it is one of the most common nervous system disorders of the elderly, the cause of PD remains uncertain. Symptoms early in the disease are movement-related, including shaking, rigidity, slowness of movement, and difficulty with walking gait. More advanced stages of the disease are typically associated with cognitive and behavioral problems, including dementia. The early motor symptoms are partially managed by administration of drugs that enhance dopaminergic signaling. However, as the disease progresses and the dopaminergic neurons in the substantia nigra continue to die, patients reach a point at which these drugs become ineffective at treating the symptoms and additionally produce the complication of dyskinesia. Effectively preventing the death of dopaminergic neurons in the substantia nigra would therefore be an ideal treatment approach for patients with PD.

MPTP (l-methyl-4-phenyl-l, 2,3,6-tetrahydropyridine) is a potent neurotoxin that selectively kills dopaminergic neurons in the substantia nigra of both mice and monkeys, causing a clinical picture resembling PD. The MPTP toxicity model can therefore be used to study the death of dopaminergic neurons with the goal of developing new treatments for PD based on neuroprotective strategies found to be effective in these neurons. To determine if P7C3A20 might

be neuroprotective in the substantia nigra, the well-characterized and popular MPTP administration regimen was employed, as developed by Tatton and Kish (1997), *Neuroscience* 77: 1037-1048, and Jakson-Lewis et al. (2007), *Nature Protocols* 2: 141-151. Here, 12 week old wild type male C57BL/6 mice were treated for 3 days with P7C3A20 (10 mg/kg i.p. twice daily) or vehicle, and on the fourth day a five day regimen of 30 mg/kg/day i.p. free base MPTP was initiated. During this five day period of MPTP administration the mice continued to receive P7C3A20 or vehicle. Mice continued to receive the same dose of P7C3A20 or vehicle every day for 21 more days, at which point they were sacrificed by transcardial perfusion with 4% paraformaldehyde. Brains were post-fixed in 4% paraformaldehyde at 4 degrees Celsius overnight and then cryoprotected with 30% sucrose in phosphate-buffered saline. Fixed brains were cut at 30 microns with a sliding microtone, and every 4th section (spaced 120 microns apart) was stained with antibodies directed against tyrosine hydroxylase (TH) (Abeam, rabbit anti-TH, 1:2500). TH-positive cells were counted in the substantia nigra area. As shown in **Figures 25A and 25B,** treatment with P7C3A20 significantly attenuates MPTP-mediated killing of substantia nigra dopaminergic neurons. These observations suggest that P7C3A20 and related compounds may form the basis of new neuroprotective strategies for preventing or slowing the progression of Parkinson's disease.

It should be appreciated by one of ordinary skill in the art that the above described PD model and other animal model can also be used to test other compounds of presently disclosed embodiments.

Example 45 Compound Provides Therapeutic Benefit in Animal Model of Huntington's Disease

Huntington's disease (HD) is an autosomal dominant neurodegenerative disease characterized by the insidious and progressive development of mood disturbances, behavioral changes, involuntary choreiform movements (ceaseless and complex writhing movements of the limbs) and cognitive impairment. HD has a prevalence of about 1 in 10,000 people in the U.S., and is caused by a polyglutamine expansion of greater than 36 repeats in the N terminus of the protein huntingtin (Htt). There are currently no treatments that delay the appearance or progression of this disease. HD is pathologically characterized by a dramatic loss of neurons in the striatum and cerebral cortex, and therapeutic strategies to protect these neurons from dying might provide new treatment options for patients. The physical symptoms of HD typically have their onset between 35-44 years of age, though onset has been reported to occur at times ranging from infancy to old age. The exact way in which HD affects an individual varies and can differ even between members of the same family, but symptoms progress predictably in most cases. The earliest symptoms

include a general lack of coordination and unsteady gait, and as the disease advances uncoordinated and jerky body movements become more apparent. More advanced stages are typically accompanied by an observable decline in mental abilities, associated with behavioral and psychiatric problems, such as anxiety, severe depression, blunted affect, egocentrism, aggression, and compulsive behaviors such as alcoholism, gambling or hypersexuality. Over time, physical abilities are gradually impeded until coordinated movement becomes very difficult, and mental abilities generally decline into dementia. Complications such as pneumonia, heart disease, eating difficulties leading to weight loss and malnutrition, and physical injury from falls reduce life expectancy to around twenty years after onset of symptoms. There is no cure for HD, and full-time care is required in later stages of disease.

Htt is a large cytoplasmic protein that interacts with over 100 other proteins, and appears to have multiple biological functions. The behavior of mutated Htt (mHtt) protein is not completely understood, but it is known to be toxic to neurons. Damage mainly occurs in the striatum, but in later stages other areas of the brain are also attacked, such as the cerebral cortex. As neuronal cell death progresses, symptoms associated with the functions of the affected brain areas appear. For example, planning and modulating movement are the main functions of the striatum, and difficulties with these tasks are frequent initial symptoms of HD. Disease initiation and progression are thought to involve in large part a conformational change in the mHtt protein due to the polyglutamine expansion, altered protein-protein interactions, abnormal protein aggregation in both the nucleus and cytoplasm and proteolysis, which in turn may lead to transcriptional dysregulation, excitotoxicity, mitochondrial dysfunction, and neuronal apoptosis. In addition to a role for a gain of new toxic properties of mHtt in HD pathology, there is increasing evidence that loss of wild-type Htt function also contributes to pathogenesis. For example, an essential role of Htt in mitotic spindle formation and mammalian neurogenesis has recently been identified.

One animal model of HD that can be employed for screening potential therapeutic agents is R6/2 transgenic mice. These mice express a mutant exon 1 of the human huntingtin gene, engineered to include an approximately 145-155 CAG repeat expansion. R6/2 mice phenocopy much of the neuropathology (striatal and cortical neuron cell death) and behavioral manifestations of clinical HD. They display progressive motor and cognitive impairments, ubiquitinated nuclear and cytoplasmic inclusions of mutant Htt, weight loss, decreased striatal and brain size, altered levels of neurotransmitters and their receptors, and premature death. They exhibit motor deficits as early as 5-6 weeks of age, display overt behavioral abnormalities at 8-9 weeks, and typically die between 11 and 13 weeks of age. R6/2 mice also display significantly lower levels of adult hippocampal neurogenesis relative to wild-type littermates, even before onset of symptoms.

In one hypothesis, P7C3 (and its derivates) may enhance the formation of neurons in the mature hippocampus by preventing death rather than promoting proliferation of these cells. As such, P7C3 is "proneurogenic" by virtue of its neuroprotective activity. It is also possible that P7C3 (and its derivates) prevents cell death and promotes cell proliferation. It was evaluated whether P7C3 might provide therapeutic benefit in R6/2 mice. P7C3 (10 mg/kg i.p. twice daily starting at 6 weeks of age) or vehicle were administered to 40 female R6/2 mice. As shown in **Figure 26A,** 50% of vehicle-treated R6/2 mice die at approximately 15 weeks of age, and treatment with P7C3 delays animal death by about three weeks. At 14 weeks of age, R6/2 mice treated with P7C3 showed improved general condition score and appearance as shown in **Figure 26B,** as compared to vehicle-treated littermates. General condition score was determined by a 3 point scoring system that was conducted blind to genotype and treatment group (score of 0 = fur looks groomed, normal posture (no hunch), clear eyes, alert; score of 1 = fur beginning to stick up, slight hunch; score of 2 = piloerection (fur sticking up), unkempt fur, hunch in back or neck area, crusty eyes). Death was monitored twice daily, and defined as either when animals were found dead, or when they were unable to right themselves after being placed on their backs with movement subsequently initiated by gentle prodding for 30 seconds. By general appearance of coat condition, grooming and spontaneous activity in the home cage, R6/2 mice treated with P7C3 also appear qualitatively better than VEH-treated R6/2 mutant mice (not shown).

It should be appreciated by one of ordinary skill in the art that the above described HD model and other animal model can also be used to test other compounds of presently disclosed embodiments.

U.S. Provisional Application No. 61/143,755 further discloses:

The term "heteroatom" as used herein generally means any atom other than carbon, hydrogen or oxygen. Preferred heteroatoms include oxygen (O), phosphorus (P), sulfur (S), nitrogen (N), silicon (S), arsenic (As), selenium (Se), and halogens, and preferred heteroatom functional groups are haloformyl, hydroxyl, aldehyde, amine, azo, carboxyl, cyanyl, thocyanyl, carbonyl, halo, hydroperoxyl, imine, aldimine, isocyanide, iscyante, nitrate, nitrile, nitrite, nitro, nitroso, phosphate, phosphono, sulfide, sulfonyl, sulfo, and sulfhydryl.

The term "alkyl," by itself or as part of another substituent, means, unless otherwise stated, a straight or branched chain, or cyclic hydrocarbon radical, or combination thereof, which is fully saturated, having the number of carbon atoms designated (i.e. C1-C8 means one to eight carbons). Examples of alkyl groups include methyl, ethyl, n-propyl, isopropyl, n-butyl, t-butyl, isobutyl, sec-butyl, cyclohexyl, (cyclohexyl)methyl, cyclopropylmethyl, homologs and isomers of, for example, n-pentyl, n-hexyl, n-heptyl, n-octyl and the like.

The term "alkenyl", by itself or as part of another substituent, means a straight or branched chain, or cyclic hydrocarbon radical, or combination thereof, which may be mono- or polyunsaturated, having the number of carbon atoms designated (i.e. C2-C8 means two to eight carbons) and one or more double bonds. Examples of alkenyl groups include vinyl, 2-propenyl, crotyl, 2-isopentenyl, 2-(butadienyl), 2,4-pentadienyl, 3-(l,4-pentadienyl) and higher homologs and isomers thereof.

The term "alkynyl", by itself or as part of another substituent, means a straight or branched chain hydrocarbon radical, or combination thereof, which may be mono- or polyunsaturated, having the number of carbon atoms designated (i.e. C2-C8 means two to eight carbons) and one or more triple bonds. Examples of alkynyl groups include ethynyl, 1- and 3-propynyl, 3-butynyl and higher homologs and isomers thereof.

The term "alkylene" by itself or as part of another substituent means a divalent radical derived from alkyl, as exemplified by $-CH_2-CH_2-CH_2-CH_2-$. Typically, an alkyl (or alkylene) group will have from 1 to 24 carbon atoms, with those groups having 10 or fewer carbon atoms being preferred in the presently disclosed embodiments. A "lower alkyl" or "lower alkylene" is a shorter chain alkyl or alkylene group, generally having eight or fewer carbon atoms.

The terms "alkoxy," "alkylamino" and "alkylthio" (or thioalkoxy) are used in their conventional sense, and refer to those alkyl groups attached to the remainder of the molecule via an oxygen atom, an amino group, or a sulfur atom, respectively.

The term "heteroalkyl," by itself or in combination with another term, means, unless otherwise stated, a stable straight or branched chain, or cyclic hydrocarbon radical, or combinations thereof, consisting of the stated number of carbon atoms and from one to three heteroatoms selected from the group consisting of O, N, Si and S, wherein the nitrogen and sulfur atoms may optionally be oxidized and the nitrogen heteroatom may optionally be quaternized. The heteroatom(s) O, N and S may be placed at any interior position of the heteroalkyl group. The heteroatom Si may be placed at any position of the heteroalkyl group, including the position at which the alkyl group is attached to the remainder of the molecule. Examples include $-CH_2-CH_2-O-CH_3$, $-CH_2-CH_2-NH-CH_3$, -CH2-CH_2-$N(CH_3)$-CH3, $-CH_2-S-CH_2-CH_3$, $-CH_2-CH_2$,-S(0)-CH_3, $-CH_2-CH_2$-S(0)2-CH3, -

CH=CH-0-CH $_3$, -Si(CH$_3$)$_3$, -CH$_2$-CH=N-OCH$_3$, and -CH=CH-N(CH3)-CH $_3$. Up to two heteroatoms may be consecutive, such as, for example, -CH$_2$-NH-OCH$_3$ and -CH$_2$-0-Si(CH $_3$)$_3$.

Similarly, the term "heteroalkylene," by itself or as part of another substituent means a divalent radical derived from heteroalkyl, as exemplified by -CH $_2$-CH $_2$-S-CH$_2$-CH $_2$- and -CH$_2$-S-CH$_2$-CH $_2$-NH-CH$_2$-. For heteroalkylene groups, heteroatoms can also occupy either or both of the chain termini (e.g., alkyleneoxy, alkylenedioxy, alkyleneamino, alkylenediamino, and the like). Still further, for alkylene and heteroalkylene linking groups, no orientation of the linking group is implied.

The terms "cycloalkyl" and "heterocycloalkyl", by themselves or in combination with other terms, represent, unless otherwise stated, cyclic versions of "alkyl" and "heteroalkyl", respectively. Accordingly, a cycloalkyl group has the number of carbon atoms designated (i.e., C3-C8 means three to eight carbons) and may also have one or two double bonds. A heterocycloalkyl group consists of the number of carbon atoms designated and from one to three heteroatoms selected from the group consisting of O, N, Si and S, and wherein the nitrogen and sulfur atoms may optionally be oxidized and the nitrogen heteroatom may optionally be quaternized. Additionally, for heterocycloalkyl, a heteroatom can occupy the position at which the heterocycle is attached to the remainder of the molecule. Examples of cycloalkyl include cyclopentyl, cyclohexyl, 1-cyclohexenyl, 3-cyclohexenyl, cycloheptyl, and the like. Examples of heterocycloalkyl include 1-(1,2,5,6-tetrahydropyrid- yl), 1-piperidinyl, 2-piperidinyl, 3-piperidinyl, 4-morpholinyl, 3-morpholinyl, tetrahydrofuran-2-yl, tetrahydrofuran-3-yl, tetrahydrothien-2-yl, tetrahydrothien-3-yl, 1-piperazinyl, 2-piperazinyl, and the like.

The terms "halo" and "halogen," by themselves or as part of another substituent, mean, unless otherwise stated, a fluorine, chlorine, bromine, or iodine atom. Additionally, terms such as "haloalkyl," are meant to include alkyl substituted with halogen atoms, which can be the same or different, in a number ranging from one to (2m'+l), where m' is the total number of carbon atoms in the alkyl group. For example, the term "halo(Cl-C4)alkyl" is mean to include trifluoromethyl, 2,2,2-trifluoroethyl, 4-chlorobutyl, 3-bromopropyl, and the like. Thus, the term "haloalkyl" includes monohaloalkyl (alkyl substituted with one halogen atom) and polyhaloalkyl (alkyl substituted with halogen atoms in a number ranging from two to (2m'+l) halogen atoms, where m' is the total number of carbon atoms in the alkyl group). The term "perhaloalkyl" means, unless otherwise stated, alkyl substituted with (2m'+l) halogen atoms, where m' is the total number of carbon atoms in the alkyl group. For example the term "perhalo(Cl-C4)alkyl" is meant to include trifluoromethyl, pentachloroethyl, l,l,l-trifluoro-2-bromo-2-chloroethyl and the like.

The term "acyl" refers to those groups derived from an organic acid by removal of the hydroxy portion of the acid. Accordingly, acyl is meant to include, for example, acetyl, propionyl, butyryl, decanoyl, pivaloyl, benzoyl and the like.

The term "aryl" means, unless otherwise stated, a polyunsaturated, typically aromatic, hydrocarbon substituent which can be a single ring or multiple rings (up to three rings) which are fused together or linked covalently. Non-limiting examples of aryl groups include phenyl, 1-naphthyl, 2-naphthyl, 4-biphenyl and 1,2,3,4-tetrahydronaphthalene.

The term heteroaryl," refers to aryl groups (or rings) that contain from zero to four heteroatoms selected from N, O, and S, wherein the nitrogen and sulfur atoms are optionally oxidized and the nitrogen heteroatom are optionally quaternized. A heteroaryl group can be attached to the remainder of the molecule through a heteroatom. Non-limiting examples of heteroaryl groups include 1-pyrrolyl, 2-pyrrolyl, 3-pyrrolyl, 3-pyrazolyl, 2-imidazolyl, 4-imidazolyl, pyrazinyl, 2-oxazolyl, 4-oxazolyl, 2-phenyl-4-oxazolyl, 5-oxazolyl, 3-isoxazolyl, 4-isoxazolyl, 5-isoxazolyl, 2-thiazolyl, 4-thiazolyl, 5-thiazolyl, 2-furyl, 3-furyl, 2-thienyl, 3-thienyl, 2-pyridyl, 3-pyridyl, 4-pyridyl, 2-pyrimidyl, 4-pyrimidyl, 5-benzothiazolyl, purinyl, 2-benzimidazolyl, 5-indolyl, 1-isoquinolyl, 5-isoquinolyl, 2-quinoxalinyl, 5-quinoxalinyl, 3-quinolyl and 6-quinolyl.

For brevity, the term "aryl" when used in combination with other terms (e.g., aryloxy, arylthioxy, arylalkyl) includes both aryl and heteroaryl rings as defined above. Thus, the term "arylalkyl" is meant to include those radicals in which an aryl group is attached to an alkyl group (e.g., benzyl, phenethyl, pyridylmethyl and the like) including those alkyl groups in which a carbon atom (e.g., a methylene group) has been replaced by, for example, an oxygen atom (e.g., phenoxymethyl, 2-pyridyloxymethyl, 3-(l-naphthyloxy)propyl, and the like).

Each of the above terms (e.g., "alkyl," "heteroalkyl," "aryl" and "heteroaryl") is meant to include both substituted and unsubstituted forms of the indicated radical. Preferred substituents for each type of radical are provided below.

Substituents for the alkyl and heteroalkyl radicals (as well as those groups referred to as alkylene, alkenyl, heteroalkylene, heteroalkenyl, alkynyl, cycloalkyl, heterocycloalkyl, cycloalkenyl and heterocycloalkenyl) can be a variety of groups selected from: -OR', =0, =NR', =N-OR', -NR'R", -SR, halogen, -SiRR"R'", -OC(0)R', -C(0)R, -C0 $_2$R , -CONRR", -OC(0)NRR", -NR"C(0)R, -NR-C(0)NR"R", -NR-S0 $_2$NR", -NR"C0 $_2$R', -NH-C(NH_2)=NH, -NR'C(NH_2)=NH, -NH-C(NH_2)=NR', -S(0)R, -S0 $_2$R , -S0 $_2$NR'R", -NR"S0 $_2$R, -CN and -N0 $_2$, in a number ranging from zero to three, with those groups having zero, one or two substituents being particularly preferred. R', R" and R " each independently refer to hydrogen, unsubstituted (Cl-

C8)alkyl and heteroalkyl, unsubstituted aryl, aryl substituted with one to three halogens, unsubstituted alkyl, alkoxy or thioalkoxy groups, or aryl-(Cl-C4)alkyl groups. When R' and R" are attached to the same nitrogen atom, they can be combined with the nitrogen atom to form a 5-, 6- or 7-membered ring. For example, -NR'R" is meant to include 1-pyrrolidinyl and 4-morpholinyl. Typically, an alkyl or heteroalkyl group will have from zero to three substituents, with those groups having two or fewer substituents being preferred in the presently disclosed embodiments. More preferably, an alkyl or heteroalkyl radical will be unsubstituted or monosubstituted. Most preferably, an alkyl or heteroalkyl radical will be unsubstituted. From the above discussion of substituents, one of skill in the art will understand that the term "alkyl" is meant to include groups such as trihaloalkyl (e.g., $-CF_3$ and $-CH_2CF_3$).

Preferred substituents for the alkyl and heteroalkyl radicals are selected from: -OR', =0, -NR'R", -SR', halogen, -SiR'R"R"', -OC(0)R, -C(0)R, -C0 $_2$R , -CONR'R", -OC(0)NR'R", -NR"C(0)R, -NR"C0 $_2$R , -NR'-S0 $_2$NR"R"', -S(0)R, -S02R', -S0 $_2$NR'R", -NR"S0 $_2$R, -CN and -N0 $_2$, where R' and R" are as defined above. Further preferred substituents are selected from: -OR', =0, -NR'R", halogen, -OC(0)R', -C0 $_2$R', -CONR'R", -OC(0)NR'R", -NR"C(0)R, -NR"C0 $_2$R , -NR'-S0 $_2$NR"R"', -S0 $_2$R , -S0 $_2$NR'R", -NR"S0 $_2$R, -CN and -N0 $_2$.

Similarly, substituents for the aryl and heteroaryl groups are varied and selected from: halogen, -OR, -OC(0)R', -NR'R", -SR', -R', -CN, -N0 $_2$, -C0 $_2$R , -CONR'R", -C(0)R', -OC(0)NR'R", -NR"C(0)R, -NR"C02R', -NR'-C(0)NR"R", -NR'-S0 $_2$NR"R"', -NH-C(NH2)=NH, -NR'C(NH_2)=NH, -NH-C(NH_2)=NR, -S(0)R', -S0 $_2$R , -S0 $_2$NR'R", -NR"S0 $_2$R, -N_3, -$CH(Ph)_2$, perfluoro(Cl-C4)alko- xy and perfluoro(Cl-C4)alkyl, in a number ranging from zero to the total number of open valences on the aromatic ring system; and where R', R" and R"' are independently selected from hydrogen, (Cl-C8)alkyl and heteroalkyl, unsubstituted aryl and heteroaryl, (unsubstituted aryl)-(Cl-C4)alkyl and (unsubstituted aryl)oxy-(Cl-C4)alkyl. When the aryl group is 1,2,3,4-tetrahydronaphthalene, it may be substituted with a substituted or unsubstituted (C3-C7)spirocycloalkyl group. The (C3-C7)spirocycloalkyl group may be substituted in the same manner as defined herein for "cycloalkyl". Typically, an aryl or heteroaryl group will have from zero to three substituents, with those groups having two or fewer substituents being preferred in the presently disclosed embodiments. In one embodiment, an aryl or heteroaryl group will be unsubstituted or monosubstituted. In another embodiment, an aryl or heteroaryl group will be unsubstituted.

Preferred substituents for aryl and heteroaryl groups are selected from: halogen, -OR', -OC(0)R, -NR'R", -SR', -R', -CN, -N0 $_2$, -C0 $_2$R , -CONR'R", -C(0)R',-OC(0)NR'R", -NR"C(0)R', -S(0)R', -S0 $_2$R', -S0 $_2$NR'R", -NR"S0 $_2$R, -N_3, -$CH(Ph)_2$, perfluoro(Cl-C4)alkoxy and

perfluoro(Cl-C4)alkyl, where R' and R" are as defined above. Further preferred substituents are selected from: halogen, -OR, -OC(0)R, -NRR", -R', -CN, -N0 $_2$, -C0 $_2$R , -CONRR", -NR"C(0)R', -S0 $_2$R', -S0 $_2$NRR", -NR"S0 $_2$R, perfluoro(Cl-C4)alkoxy and perfluoro(Cl-C4)alkyl.

The substituent -C0 $_2$H, as used herein, includes bioisosteric replacements therefor; see, e.g., The Practice of Medicinal Chemistry; Wermuth, C. G., Ed.; Academic Press: New York, 1996; p. 203.

Two of the substituents on adjacent atoms of the aryl or heteroaryl ring may optionally be replaced with a substituent of the formula -T-C(0)-(CH $_2$)q-U-, wherein T and U are independently -NH-, -0-, -CH_2- or a single bond, and q is an integer of from 0 to 2. Alternatively, two of the substituents on adjacent atoms of the aryl or heteroaryl ring may optionally be replaced with a substituent of the formula -A-(CH2)r-B-, wherein A and B are independently -CH_2-, -0-, -NH-, -S-, -S(O)-, -S(0) $_2$-, -S(0) $_2$NR'- or a single bond, and r is an integer of from 1 to 3. One of the single bonds of the new ring so formed may optionally be replaced with a double bond. Alternatively, two of the substituents on adjacent atoms of the aryl or heteroaryl ring may optionally be replaced with a substituent of the formula -(CH_2)s-X-(CH_2)t- -, where s and t are independently integers of from 0 to 3, and X is -0-, -NR'-, -S-, -S(O)-, -S(0) $_2$-, or -S(0) $_2$NR-. The substituent R' in -NR- and -S(0) $_2$NR'- is selected from hydrogen or unsubstituted (C 1-C6)alkyl.
