## (54) Title: DIHYDROOXADIAZINONES

(57) Abstract: The present invention provides dihydrooxydiazinone compounds of general formula (I) : in which R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, and R<sup>4</sup>, are as defined herein, methods of preparing said compounds, intermediate compounds useful for preparing said compounds, pharmaceutical compositions and combinations comprising said compounds and the use of said compounds for manufacturing pharmaceutical compositions for the treatment or prophylaxis of diseases, in particular of hyperproliferative diseases, as a sole agent or in combination with other active ingredients.

## DIHYDROOXADIAZINONES

The present invention provides dihydrooxadiazinone compounds of general formula (I) as described and defined herein, methods of preparing said compounds, pharmaceutical compositions and the use of said compounds for the treatment or prophylaxis of diseases, in particular of hyperproliferative diseases.

**BACKGROUND**

Cancer kills over 550,000 people in the United States and over 8 million people world-wide each year. New agents, including small molecules, molecules that impact tissue-specific growth requirements, and immunomodulatory agents, have been shown to benefit a subset of patients whose cancers have unique genomic mutations or other characteristics. Unfortunately, many cancer patients are still left without effective therapeutic options.

One approach to identify new anti-cancer agents is phenotypic screening to discover novel small molecules displaying strong selectivity between cancer cell lines, followed by predictive chemogenomics to identify the cell features associated with drug response. In the 1990s, Weinstein and colleagues demonstrated that the cytotoxic profile of a compound can be used to identify cellular characteristics, such as gene-expression profiles and DNA copy number, which correlate with drug sensitivity. The ability to identify the features of cancer cell lines that mediate their response to small molecules has strongly increased in recent years with automated high-throughput chemosensitivity testing of large panels of cell lines coupled with comprehensive genomic and phenotypic characterization of the cell lines. Phenotypic observations of small molecule sensitivity can be linked to expression patterns or somatic alterations, as in the case of trastuzumab-sensitive HER2-amplified breast cancer or erlotinib-sensitive EGFR-mutant lung cancer.

Phenotypic screening identified some of the compounds known in the literature to be PDE3 inhibitors to be useful for the treatment of certain cancers. Co-expression of PDE3A and/or PDE3B and Schlafen 12 (SLFN12) polynucleotides or polypeptides are typically required for cells to be sensitive. PDE3A/B inhibitors which cause drug sensitivity have been found to stabilize the formation of a complex between PDE3A or PDE3B and SLFN12. PDE3A/B inhibitors which do not cause cell sensitivity typically do not stabilize the PDE3A- or PDE3B - SLFN12 complex.

Several PDE-3 inhibitors such as milrinone, cilostazol, and levosimendan have been approved for clinical treatment of cardiovascular indications or thrombocythemia (anagrelide), but not for cancer indication. The most recent quality review of PDE inhibitors (Nature Reviews Drug Discovery 13, 290-314, (2014)) barely mentions cancer.

5 From WO 2014/164704, WO2017/027854, and WO2017/134231 some PDE3 inhibitors are known.

Especially the cardiac mode of action mediated unwanted effects of PDE-3 inhibitors (Movsesian SKukreja, S.H. Francis et al. (eds.), Phosphodiesterases as Drug Targets, Handbook of Experimental Pharmacology 204, 2011; p 237ff) may limit their  
10 therapeutic use when PDE3-inhibiting agents are used on a short- or/and long term basis, e.g. in cancer patients and a suitable therapeutic window is needed.

Some dihydrooxydiazinones are known, however, the state of the art does not describe the dihydrooxadiazinone compounds of general formula (I) of the present invention as described and defined herein.

## 15 SUMMARY

It has now been found, and this constitutes at least in part one basis of the present invention, that the compounds of the present invention have surprising and advantageous properties.

In particular, the compounds of the present invention have surprisingly been  
20 found to inhibit tumor cell proliferation with  $IC_{50}$  values of < 100 nM in e.g. HeLa cells. Additionally, the compounds require higher concentrations for PDE3A and/or PDE3B inhibition where  $IC_{50}$  values for enzymatic PDE3A and/or PDE3B inhibition may be > 2.5 times higher than  $IC_{50}$  values for tumor cell proliferation. Without wishing to be bound by theory, this distinction in inhibitory properties may be associated with PDE3A-SLFN12  
25 complex induction and/or improved pharmacokinetic parameters *in vitro* or *in vivo* and/or improved physicochemical properties and/or improved safety pharmacological properties. With these advantageous properties, the compounds described herein may therefore be used for the treatment or prophylaxis of hyperproliferative diseases, such as cancer diseases.

30 The present invention provides compounds of general formula (I) which modulate formation of a PDE3A- and/or PDE3B-SLFN12 complex, methods for their preparation, pharmaceutical composition and the use thereof and methods of treatment or prophylaxis of diseases, in particular of hyperproliferative diseases more particularly of cancer diseases. These and other features of the present teachings are set forth herein.

## DEFINITIONS

Unless defined otherwise, all technical and scientific terms used herein have the  
meaning commonly understood by a person skilled in the art to which this invention  
20 belongs. The following references provide one of skill with a general definition of many  
of the terms used in this invention: Singleton et al., Dictionary of Microbiology and  
Molecular Biology (2nd ed. 1994); The Cambridge Dictionary of Science and Technology  
(Walker ed., 1988); The Glossary of Genetics, 5th Ed., R. Rieger et al. (eds.), Springer  
Verlag (1991); and Hale & Marham, The Harper Collins Dictionary of Biology (1991). As  
25 used herein, the following terms have the meanings ascribed to them below, unless  
specified otherwise.

Structures drawn include all permissible rotations about bonds.

The term "substituted" means that one or more hydrogen atoms on the  
designated atom or group are replaced with a selection from the indicated group,  
30 provided that the designated atom's normal valency under the existing circumstances is  
not exceeded. Combinations of substituents and/or variables are permissible.

The term "optionally substituted" means that the number of substituents can be  
equal to or different from zero. Unless otherwise indicated, it is possible that optionally  
substituted groups are substituted with as many optional substituents as can be

accommodated by replacing a hydrogen atom with a non-hydrogen substituent on any available carbon or nitrogen atom. Commonly, it is possible for the number of optional substituents, when present, to be 1, 2, 3, in particular 1, or 2.

As used herein, the term "one or more", *e.g.* in the definition of the substituents of the compounds of general formula (I) of the present invention, means 1, 2, 3, 4 or 5, particularly 1, 2, 3 or 4, more particularly 1, 2 or 3, even more particularly 1 or 2".

As used herein, an oxo substituent represents an oxygen atom, which is bound to a carbon atom or to a sulfur atom via a double bond.

The term "ring substituent" means a substituent attached to an aromatic or nonaromatic ring which replaces an available hydrogen atom on the ring.

Should a composite substituent be composed of more than one parts, *e.g.* (Ci-C<sub>4</sub>-alkyl)-O-(Ci-C<sub>4</sub>-alkyl)-, a hyphen at the beginning or at the end of such a composite substituent indicates the point of attachment of said composite substituent to the rest of the molecule. Should the composite substituent be substituted said substituted may be bound at any suitable carbon atom of the composite substituent.

Should a ring, comprising carbon atoms and optionally one or more heteroatoms, such as nitrogen, oxygen or sulfur atoms for example, be substituted with a substituent, it is possible for said substituent to be bound at any suitable position of said ring, be it bound to a suitable carbon atom and/or to a suitable heteroatom.

The term "comprising" when used in the specification includes "consisting of".

If within the present text any item is referred to as "as mentioned herein", it means that it may be mentioned anywhere in the present text.

An analog may include an unnatural amino acid.

In this disclosure, "comprises," "comprising," "containing" and "having" and the  
 25 like can have the meaning ascribed to them in U.S. Patent law and can mean "includes," "including," and the like; "consisting essentially of" or "consists essentially" likewise has the meaning ascribed in U.S. Patent law and the term is open-ended, allowing for the presence of more than that which is recited so long as basic or novel characteristics of that which is recited is not changed by the presence of more than that which is recited,

The invention is further based at least in part on the discovery that the compounds of formula (I) are PDE3A- or PDE3B-SLFN12 complex modulators

Accordingly, in a further embodiment the invention further provides methods of  
 selecting a subject as having a cancer that responds to a PDE3A- or PDE3B-SLFN12  
 15 complex modulator, especially a compound of formula (I), where the selection method  
 involves detecting co-expression of PDE3A and/or PDE3B and Schlafen 12 (SLFN12)  
 polypeptides or polynucleotides, in a cancer cell derived from such subjects.

In a further embodiment, the invention provides methods of determining that the  
 expression of CREB3L1 or SLFN12 polynucleotide or polypeptide is reduced or is  
 20 undetectable in a cancer cell that has acquired resistance to a PDE3A- and/or PDE3B-  
 SLFN12 complex modulator in order to prevent ineffective treatment with a compound of  
 formula (I).

Accordingly, the invention provides methods comprising the steps of

- 25 - identifying subjects that have a malignancy that is likely to respond to  
 PDE3A- and/or PDE3B-SLF12 complex modulator treatment, especially a  
 treatment with a compound of formula (I), based on the level of PDE3A and/or  
 PDE3B and SLFN12 expression in a subject biological sample comprising a  
 cancer cell
- administering an effective amount of a compound of formula (I).

30 In particular embodiments, the invention provides methods comprising the steps of

- identifying subjects that have a malignancy that is resistant to PDE3A- and/or  
 PDE3B-SLF12 complex modulator treatment, especially to the treatment of a  
 compound of formula (I), based on a loss or reduction in the level of  
 CREB3L1 or SLFN12 expression relative to a reference and

- subsequently excluding them from an envisaged treatment schedule with a compound of formula (I).

### Compound Forms and Salts

5           It is possible for the compounds of formula (I) to exist in free form, *e.g.* as a free base, or as a free acid, or as a zwitterion, or to exist in the form of a salt. Said salt may be any salt, either an organic or inorganic addition salt, particularly any pharmaceutically acceptable organic or inorganic addition salt, which is customarily used in pharmacy, or which is used, for example, for isolating or purifying the compounds of the present  
10 invention.

A salt, for example, can be formed between an anion and a positively charged substituent (*e.g.*, amino) on a compound described herein. Suitable anions include chloride, bromide, iodide, sulfate, nitrate, phosphate, citrate, methanesulfonate, trifluoroacetate, and acetate. Likewise, a salt can also be formed between a cation and a  
15 negatively charged substituent (*e.g.*, carboxylate) on a compound described herein. Suitable cations include sodium ion, potassium ion, magnesium ion, calcium ion, and an ammonium cation such as tetramethylammonium ion. Examples of prodrugs include  $C_{1-6}$  alkyl esters of carboxylic acid groups, which, upon administration to a subject, are capable of providing active compounds.

20 A suitable pharmaceutically acceptable salt of the compounds of the present invention may be, for example, an acid-addition salt of a compound of the present invention bearing a nitrogen atom, in a chain or in a ring, for example, which is sufficiently basic, such as an acid-addition salt with an inorganic acid, or "mineral acid", such as hydrochloric, hydrobromic, hydroiodic, sulfuric, sulfamic, bisulfuric, phosphoric,  
25 or nitric acid, for example, or with an organic acid, such as formic, acetic, acetoacetic, pyruvic, trifluoroacetic, propionic, butyric, hexanoic, heptanoic, undecanoic, lauric, benzoic, salicylic, 2-(4-hydroxybenzoyl)-benzoic, camphoric, cinnamic, cyclopentanepropionic, digluconic, 3-hydroxy-2-naphthoic, nicotinic, pamoic, pectinic, 3-phenylpropionic, pivalic, 2-hydroxyethanesulfonic, itaconic, trifluoromethanesulfonic,  
30 dodecylsulfuric, ethanesulfonic, benzenesulfonic, para-toluenesulfonic, methanesulfonic, 2-naphthalenesulfonic, naphthalenedisulfonic, camphorsulfonic acid, citric, tartaric, stearic, lactic, oxalic, malonic, succinic, malic, adipic, alginic, maleic, fumaric, D-gluconic, mandelic, ascorbic, glucoheptanoic, glycerophosphoric, aspartic, sulfosalicylic, or thiocyanic acid, for example.

35 Further examples of suitable acid salts include acetate, adipate, alginate,

aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, citrate, camphorate, camphorsulfonate, digluconate, dodecylsulfate, ethanesulfonate, formate, fumarate, glucoheptanoate, glycolate, hemisulfate, heptanoate, hexanoate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxyethanesulfonate, lactate, maleate, malonate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, nitrate, palmoate, pectinate, persulfate, 3-phenylpropionate, phosphate, picrate, pivalate, propionate, salicylate, succinate, sulfate, tartrate, thiocyanate, tosylate and undecanoate. Other acids, such as oxalic, while not in themselves pharmaceutically acceptable, may be employed in the preparation of salts useful as intermediates in obtaining the compounds of the present invention and their pharmaceutically acceptable acid addition salts.

Further, another suitably pharmaceutically acceptable salt of a compound of formula (I), which is sufficiently acidic, is an alkali metal salt, for example a sodium or potassium salt, an alkaline earth metal salt, for example a calcium, magnesium or strontium salt, or an aluminium or a zinc salt, or an ammonium salt derived from ammonia or from an organic primary, secondary or tertiary amine having 1 to 20 carbon atoms, such as ethylamine, diethylamine, triethylamine, ethyldiisopropylamine, monoethanolamine, diethanolamine, triethanolamine, dicyclohexylamine, dimethylaminoethanol, diethylaminoethanol, tris(hydroxymethyl)aminomethane, procaine, dibenzylamine, N-methylmorpholine, arginine, lysine, 1,2-ethylenediamine, N-methylpiperidine, N-methyl-glucamine, N,N-dimethyl-glucamine, N-ethyl-glucamine, 1,6-hexanediamine, glucosamine, sarcosine, serinol, 2-amino-1,3-propanediol, 3-amino-1,2-propanediol, 4-amino-1,2,3-butanetriol, or a salt with a quaternary ammonium ion having 1 to 20 carbon atoms, such as tetramethylammonium, tetraethylammonium, tetra(n-propyl)ammonium, tetra(n-butyl)ammonium, N-benzyl-N,N,N-trimethylammonium, choline or benzalkonium.

In certain embodiments salts are derived from appropriate bases include alkali metal (*e.g.*, sodium), alkaline earth metal (*e.g.*, magnesium), ammonium and N-(alkyl)<sub>4</sub><sup>+</sup> salts. The present invention also envisions the quaternization of any basic nitrogen-containing groups of the compounds disclosed herein. Water or oil-soluble or dispersible products may be obtained by such quaternization. Salt forms of the compounds of any of the formulae herein can be amino acid salts of carboxyl groups (*e.g.*, L-arginine, -lysine, -histidine salts).

Lists of suitable salts are found in Remington's Pharmaceutical Sciences, 17th ed., Mack Publishing Company, Easton, Pa., 1985, p. 1418; Journal of Pharmaceutical Science, 66, 2 (1977); and "Pharmaceutical Salts: Properties, Selection, and Use A Handbook; Wermuth, C. G. and Stahl, P. H. (eds.) Verlag Helvetica Chimica Acta, Zurich, 2002

[ISBN 3-906390-26-8] each of which is incorporated herein by reference in their entireties.

Those skilled in the art will further recognise that it is possible for acid addition salts of the claimed compounds to be prepared by reaction of the compounds with the appropriate inorganic or organic acid via any of a number of known methods. Alternatively, alkali and alkaline earth metal salts of acidic compounds of the present invention are prepared by reacting the compounds of the present invention with the appropriate base via a variety of known methods.

The present invention includes all possible salts of the compounds of the present invention as single salts, or as any mixture of said salts, in any ratio.

The neutral forms of the compounds may be regenerated by contacting the salt with a base or acid and isolating the parent compound in the conventional manner. The parent form of the compound differs from the various salt forms in certain physical properties, such as solubility in polar solvents, but otherwise the salts are equivalent to the parent form of the compound for the purposes of the present invention.

In the present text, in particular in the Experimental Section, for the synthesis of intermediates and of examples of the present invention, when a compound is mentioned as a salt form with the corresponding base or acid, the exact stoichiometric composition of said salt form, as obtained by the respective preparation and/or purification process, is, in most cases, unknown.

Unless specified otherwise, suffixes to chemical names or structural formulae relating to salts, such as "hydrochloride", "trifluoroacetate", "sodium salt", or "x HCl", "x CF<sub>3</sub>COOH", "x Na<sup>+</sup>", for example, mean a salt form, the stoichiometry of which salt form not being specified.

This applies analogously to cases in which synthesis intermediates or example compounds or salts thereof have been obtained, by the preparation and/or purification processes described, as solvates, such as hydrates, with (if defined) unknown stoichiometric composition.

In addition to salt forms, the present invention provides compounds which are in a prodrug form. Prodrugs of the compounds described herein are those compounds that undergo chemical changes under physiological conditions to provide the compounds of the present invention. Additionally, prodrugs can be converted to the compounds of the present invention by chemical or biochemical methods in an ex vivo environment. For example, prodrugs can be slowly converted to the compounds of the present invention when placed in a transdermal patch reservoir with a suitable enzyme or chemical

reagent. Prodrugs are often useful because, in some situations, they may be easier to administer than the parent drug. They may, for instance, be more bioavailable by oral administration than the parent drug. The prodrug may also have improved solubility in pharmacological compositions over the parent drug. A wide variety of prodrug derivatives are known in the art, such as those that rely on hydrolytic cleavage or oxidative activation of the prodrug. An example, without limitation, of a prodrug would be a compound of the present invention which is administered as an ester (the "prodrug"), but then is metabolically hydrolyzed to the carboxylic acid, the active entity. Additional examples include peptidyl derivatives of a compound of the present invention.

The compounds of the present invention can exist as a hydrate, or as a solvate, wherein the compounds of the present invention contain polar solvents, in particular water, methanol or ethanol for example, as structural element of the crystal lattice of the compounds. It is possible for the amount of polar solvents, in particular water, to exist in a stoichiometric or non-stoichiometric ratio. In the case of stoichiometric solvates, e.g. a hydrate, hemi-, (semi-), mono-, sesqui-, di-, tri-, tetra-, penta- etc. solvates or hydrates, respectively, are possible. The present invention includes all such hydrates or solvates.

The present invention also includes various hydrate and solvate forms of the compounds.

The compounds of the present invention may also contain unnatural proportions of atomic isotopes at one or more of the atoms that constitute such compounds. For example, the compounds may be radiolabeled with radioactive isotopes, such as for example tritium ( $^3\text{H}$ ), iodine-125 ( $^{125}\text{I}$ ) or carbon-14 ( $^{14}\text{C}$ ). All isotopic variations of the compounds of the present invention, whether radioactive or not, are intended to be encompassed within the scope of the present invention. particularly deuterium-containing compounds of formula (I).

formula (Ia)

Formula (Ia) shows the positions D<sup>1</sup>, D<sup>2</sup>, D<sup>3</sup> and D<sup>4</sup> in which any one of the hydrogen atoms may be exchanged by a deuterium atom. Additionally in residues R<sup>1</sup>-R<sup>4</sup> if these residues contain a heteroatom-H or carbon-H bond accessible for a chemical reaction

such an exchange may be possible. Hydrogen atoms can be replaced by deuterium atoms using methods known to those with ordinary skill in the art to obtain a heteroatom-D or carbon-D bond. Anyone of R<sup>1</sup>, R<sup>2</sup>, or R<sup>4</sup> themselves can also be deuterium instead of hydrogen.

5           Thus one aspect of the invention are those compounds wherein independently anyone of R<sup>1</sup>, R<sup>2</sup>, or R<sup>4</sup> is deuterium and/or anyone of the hydrogen atoms as shown in formula (I) are replaced by a deuterium atom and or anyone of R<sup>1</sup>, R<sup>2</sup>, R<sup>3</sup>, or R<sup>4</sup> bears a deuterium atom at a chemically accessible position or any combination of positions being deuterated at the same time.

10           The term "Isotopic variant" of a compound or a reagent is defined as a compound exhibiting an unnatural proportion of one or more of the isotopes that constitute such a compound. The term "Isotopic variant of the compound of general formula (I)" is defined as a compound of general formula (I) exhibiting an unnatural proportion of one or more of the isotopes that constitute such a compound. The expression "unnatural proportion"

15 means a proportion of such isotope which is higher than its natural abundance. The natural abundances of isotopes to be applied in this context are described in "Isotopic Compositions of the Elements 1997", Pure Appl. Chem., 70(1), 217-235, 1998. Examples of such isotopes include stable and radioactive isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorus, sulfur, fluorine, chlorine, bromine and iodine, such as <sup>2</sup>H (deuterium), <sup>3</sup>H (tritium), <sup>11</sup>C, <sup>13</sup>C, <sup>14</sup>C, <sup>15</sup>N, <sup>17</sup>O, <sup>18</sup>O, <sup>32</sup>P, <sup>33</sup>P, <sup>33</sup>S, <sup>34</sup>S, <sup>35</sup>S, <sup>36</sup>S, <sup>18</sup>F, <sup>36</sup>Cl, <sup>82</sup>Br, <sup>123</sup>I, <sup>124</sup>I, <sup>125</sup>I, <sup>129</sup>I and <sup>131</sup>I, respectively.

20

With respect to the treatment and/or prophylaxis of the diseases specified herein the isotopic variant(s) of the compounds of general formula (I) may contain deuterium ("deuterium-containing compounds of general formula (I)"). Isotopic variants of the

25 compounds of general formula (I) in which one or more radioactive isotopes, such as <sup>3</sup>H or <sup>14</sup>C, are incorporated are useful e.g. in drug and/or substrate tissue distribution studies. These isotopes are particularly preferred for the ease of their incorporation and detectability. Positron emitting isotopes such as <sup>18</sup>F or <sup>11</sup>C may be incorporated into a compound of general formula (I). These isotopic variants of the compounds of general

30 formula (I) are useful for *in vivo* imaging applications. Deuterium-containing and <sup>13</sup>C-containing compounds of general formula (I) can be used in mass spectrometry analyses in the context of preclinical or clinical studies.

Isotopic variants of the compounds of general formula (I) can generally be prepared by methods known to a person skilled in the art, such as those described in the

35 schemes and/or examples herein, by substituting a reagent for an isotopic variant of said

reagent, preferably for a deuterium-containing reagent. Depending on the desired sites of deuteration, in some cases deuterium from D<sub>2</sub>O can be incorporated either directly into the compounds or into reagents that are useful for synthesizing such compounds. Deuterium gas is also a useful reagent for incorporating deuterium into molecules.

5 Catalytic deuteration of olefinic bonds and acetylenic bonds is a direct route for incorporation of deuterium. Metal catalysts (i.e. Pd, Pt, and Rh) in the presence of deuterium gas can be used to directly exchange deuterium for hydrogen in functional groups containing hydrocarbons. A variety of deuterated reagents and synthetic building blocks are commercially available from companies such as for example C/D/N Isotopes,  
10 Quebec, Canada; Cambridge Isotope Laboratories Inc., Andover, MA, USA; and CombiPhos Catalysts, Inc., Princeton, NJ, USA.

The term "deuterium-containing compound of general formula (I)" is defined as a compound of general formula (I), in which one or more hydrogen atom(s) is/are replaced by one or more deuterium atom(s) and in which the abundance of deuterium at each  
15 deuterated position of the compound of general formula (I) is higher than the natural abundance of deuterium, which is about 0.015%. Particularly, in a deuterium-containing compound of general formula (I) the abundance of deuterium at each deuterated position of the compound of general formula (I) is higher than 10%, 20%, 30%, 40%, 50%, 60%, 70% or 80%, preferably higher than 90%, 95%, 96% or 97%, even more preferably  
20 higher than 98% or 99% at said position(s). It is understood that the abundance of deuterium at each deuterated position is independent of the abundance of deuterium at other deuterated position(s).

The selective incorporation of one or more deuterium atom(s) into a compound of general formula (I) may alter the physicochemical properties (such as for example acidity  
25 [C. L. Perrin, et al., J. Am. Chem. Soc, 2007, 129, 4490], basicity [C. L. Perrin et al., J. Am. Chem. Soc, 2005, 127, 9641], lipophilicity [B. Testa et al., Int. J. Pharm., 1984, 19(3), 271]) and/or the metabolic profile of the molecule and may result in changes in the ratio of parent compound to metabolites or in the amounts of metabolites formed. Such changes may result in certain therapeutic advantages and hence may be preferred in  
30 some circumstances. Reduced rates of metabolism and metabolic switching, where the ratio of metabolites is changed, have been reported (A. E. Mutlib et al., Toxicol. Appl. Pharmacol., 2000, 169, 102). These changes in the exposure to parent drug and metabolites can have important consequences with respect to the pharmacodynamics, tolerability and efficacy of a deuterium-containing compound of general formula (I). In  
35 some cases deuterium substitution reduces or eliminates the formation of an undesired or toxic metabolite and enhances the formation of a desired metabolite (e.g. Nevirapine:

A. M. Sharma et al., Chem. Res. Toxicol., 2013, 26, 410; Efavirenz: A. E. Mutlib et al., Toxicol. Appl. Pharmacol., 2000, 169, 102). In other cases the major effect of deuteration is to reduce the rate of systemic clearance. As a result, the biological half-life of the compound is increased. The potential clinical benefits would include the ability to maintain similar systemic exposure with decreased peak levels and increased trough levels. This could result in lower side effects and enhanced efficacy, depending on the particular compound's pharmacokinetic/ pharmacodynamic relationship. ML-337 (C. J. Wenthur et al., J. Med. Chem., 2013, 56, 5208) and Odanacatib (K. Kassahun et al., WO2012/112363) are examples for this deuterium effect. Still other cases have been reported in which reduced rates of metabolism result in an increase in exposure of the drug without changing the rate of systemic clearance (*e.g.* Rofecoxib: F. Schneider et al., Arzneimittel. Forsch. / Drug. Res., 2006, 56, 295; Telaprevir: F. Maltais et al., J. Med. Chem., 2009, 52, 7993). Deuterated drugs showing this effect may have reduced dosing requirements (*e.g.* lower number of doses or lower dosage to achieve the desired effect) and/or may produce lower metabolite loads.

A compound of general formula (I) may have multiple potential sites of attack for metabolism. To optimize the above-described effects on physicochemical properties and metabolic profile, deuterium-containing compounds of general formula (I) having a certain pattern of one or more deuterium-hydrogen exchange(s) can be selected. Particularly, the deuterium atom(s) of deuterium-containing compound(s) of general formula (I) is/are attached to a carbon atom and/or is/are located at those positions of the compound of general formula (I), which are sites

In some aspects, the compounds of formula (I) may be isomers. "Isomers" are different compounds that have the same molecular formula. "Stereoisomers" are isomers that differ only in the way the atoms are arranged in space. As used herein, the term "isomer" includes any and all geometric isomers and stereoisomers. For example, "isomers" include geometric double bond cis- and trans-isomers, also termed E- and Z-isomers; R- and S-enantiomers; diastereomers, (d)-isomers and (l)-isomers, racemic mixtures thereof; and other mixtures thereof, as falling within the scope of this invention

The symbol ---- denotes a bond that can be a single or a double bond as described herein. Provided herein are various geometric isomers and mixtures thereof resulting from the arrangement of substituents around a carbon-carbon double bond or arrangement of substituents around a carbocyclic ring. Substituents around a carbon-carbon double bond are designated as being in the "Z" or "E" configuration wherein the

terms "Z" and "E" are used in accordance with IUPAC standards. Unless otherwise specified, structures depicting double bonds encompass both the "E" and "Z" isomers.

Substituents around a carbon-carbon double bond alternatively can be referred to as "cis" or "trans," where "cis" represents substituents on the same side of the double  
5 bond and "trans" represents substituents on opposite sides of the double bond. The arrangement of substituents around a carbocyclic ring can also be designated as "cis" or "trans." The term "cis" represents substituents on the same side of the plane of the ring, and the term "trans" represents substituents on opposite sides of the plane of the ring. Mixtures of compounds wherein the substituents are disposed on both the same and  
10 opposite sides of plane of the ring are designated "cis/trans."

The compounds of the present invention optionally contain one or more asymmetric centres, depending upon the location and nature of the various substituents desired, which are e.g. carbon atoms having four different substituents. It is possible that one or more asymmetric carbon atoms are present in the (R) or (S) configuration, which  
15 can result in racemic mixtures in the case of a single asymmetric centre, and in diastereomeric mixtures in the case of multiple asymmetric centres. The term "(±)" is used to designate a racemic mixture where appropriate. In certain instances, it is possible that asymmetry also be present due to restricted rotation about a given bond, for example, the central bond adjoining two substituted aromatic rings of the specified  
20 compounds. When a compound is an enantiomer, the stereochemistry at each chiral carbon can be specified by either (R) or (S). Resolved compounds whose absolute configuration is unknown can be designated (+) or (-) depending on the direction (dextro- or levorotatory) which they rotate plane polarized light at the wavelength of the sodium D line. Certain of the compounds described herein contain one or more asymmetric centers  
25 and can thus give rise to enantiomers, diastereomers, and other stereoisomeric forms that can be defined, in terms of absolute stereochemistry at each asymmetric atom, as (R)- or (S)-. The present chemical entities, pharmaceutical compositions and methods are meant to include all such possible isomers, including racemic mixtures, optically substantially pure forms and intermediate mixtures.

30 Preferred compounds are those which produce the more desirable biological activity. Separated, pure or partially purified isomers and stereoisomers or racemic or diastereomeric mixtures of the compounds of the present invention are also included within the scope of the present invention. The purification and the separation of such materials can be accomplished by standard techniques known in the art including chiral

high pressure liquid chromatography (HPLC), the formation and crystallization of chiral salts, or prepared by asymmetric syntheses.

The optical isomers can be obtained by resolution of the racemic mixtures according to conventional processes, for example, by the formation of diastereoisomeric salts using an optically active acid or base or formation of covalent diastereomers. Examples of appropriate acids are tartaric, diacetyltartaric, ditoluoyltartaric and camphorsulfonic acid. Mixtures of diastereoisomers can be separated into their individual diastereomers on the basis of their physical and/or chemical differences by methods known in the art, for example, by chromatography or fractional crystallisation. The optically active bases or acids are then liberated from the separated diastereomeric salts. A different process for separation of optical isomers involves the use of chiral chromatography (*e.g.*, HPLC columns using a chiral phase), with or without conventional derivatisation, optimally chosen to maximise the separation of the enantiomers. Suitable HPLC columns using a chiral phase are commercially available, such as those manufactured by Daicel, *e.g.*, Chiracel OD and Chiracel OJ, for example, among many others, which are all routinely selectable. Enzymatic separations, with or without derivatisation, are also useful. The optically active compounds of the present invention can likewise be obtained by chiral syntheses utilizing optically active starting materials.

In order to distinguish different types of isomers from each other reference is made to IUPAC Rules Section E (Pure Appl Chem 45, 11-30, 1976).

The present invention includes all possible stereoisomers of the compounds of the present invention as single stereoisomers, or as any mixture of said stereoisomers, *e.g.* (R)- or (S)- isomers, in any ratio. Preferred is the stereoisomer which shows the desired effect. For compounds of formula (I) wherein  $R^4$ =methyl it is discovered that the compounds having said methyl group in the S-configuration do have a significantly better pharmacological effect.

Thus as one aspect of the invention for the configuration of the alkyl group in  $R^4$  the invention preferably includes those compounds in which  $R^4$ =C<sub>1</sub>-C<sub>3</sub>-alkyl, more particularly  $R^4$ =methyl with S-configuration as indicated in formula (Ia)

formula (Ia)

Isolation of a single stereoisomer, e.g. a single enantiomer or a single diastereomer, of a compound of the present invention is achieved by any suitable state of the art method, such as chromatography, especially chiral chromatography, for example.

Further, it is possible for the compounds of the present invention to exist as tautomers. For example, any compound of the present invention which contains an imidazopyridine moiety as a heteroaryl group for example can exist as a 1H tautomer, or a 3H tautomer, or even a mixture in any amount of the two tautomers, namely :

10

The present invention includes all possible tautomers of the compounds of the present invention as single tautomers, or as any mixture of said tautomers, in any ratio.

Further, the compounds of the present invention can potential exist as N-oxides, which are defined in that at least one nitrogen of the compounds of the present invention is oxidised. The present invention includes all such chemically possible N-oxides.

15

Furthermore, the present invention includes all possible crystalline forms, or polymorphs, of the compounds of the present invention, either as single polymorph, or as a mixture of more than one polymorph, in any ratio.

Moreover, the present invention also includes prodrugs of the compounds according to the invention. The term "prodrugs" here designates compounds which themselves can be biologically active or inactive, but are converted (for example metabolically or hydrolytically) into compounds according to the invention during their residence time in the body.

20

Thus the present invention includes prodrugs of the compounds of formula (I).

25

In yet another embodiment the present invention includes stereoisomers, tautomers, an N-oxides, hydrates, solvates, or a salts, or a mixture of same of a compounds of formula (I).

In another embodiment the present invention includes stereoisomers, tautomers, hydrates, solvates, or a salts, or a mixture of same of a compounds of formula (I).

## 10   **General synthesis of the compounds of formula (I)**

The compounds according to the invention of general formula (I) can be prepared according to the following schemes 1 through 9. The schemes and procedures described below illustrate synthetic routes to the compounds of general formula (I) of the invention and are not intended to be limiting. It is clear to the person skilled in the art that the order of transformations as exemplified in schemes 1 through 9 can be modified in various ways. The order of transformations exemplified in these schemes is therefore not intended to be limiting. In addition, interconversion of any of the substituents,  $R^1$ ,  $R^2$ ,  $R^3$ , or  $R^4$  can be achieved before and/or after the exemplified transformations. These modifications can be such as the introduction of protecting groups, cleavage of protecting groups, reduction or oxidation of functional groups, halogenation, metallation, substitution or other reactions known to the person skilled in the art. These transformations include those which introduce a functionality which allows for further interconversion of substituents. Appropriate protecting groups and their introduction and cleavage are well-known to the person skilled in the art (see for example T.W. Greene and P.G.M. Wuts in *Protective Groups in Organic Synthesis*, 3<sup>rd</sup> edition, Wiley 1999). Specific examples are described in the subsequent paragraphs.

Seven routes for the preparation of compounds of general formula (I) are described in schemes 1 through 9.

### COMBINATIONS

In accordance with another aspect, the present invention provides pharmaceutical  
10 combinations, in particular medicaments, comprising at least one compound of general formula (I) of the present invention and at least one or more further active ingredients, in particular for the treatment and/or prophylaxis of a hyperproliferative disease, a cancer disease.

Particularly, the present invention provides a pharmaceutical combination, which  
15 comprises:

- one or more first active ingredients, in particular compounds of general formula (I) as defined *supra*, and
- one or more further active ingredients, in particular a hyperproliferative disease, a cancer disease.

20 The term "combination" in the present invention is used as known to persons skilled in the art, it being possible for said combination to be a fixed combination, a non-fixed combination or a kit-of-parts.

A "fixed combination" in the present invention is used as known to persons skilled in the art and is defined as a combination wherein, for example, a first active ingredient, such  
25 as one or more compounds of general formula (I) of the present invention, and a further active ingredient are present together in one unit dosage or in one single entity. One example of a "fixed combination" is a pharmaceutical composition wherein a first active ingredient and a further active ingredient are present in admixture for simultaneous administration, such as e.g. in a formulation. Another example of a "fixed combination" is  
30 a pharmaceutical combination wherein a first active ingredient and a further active ingredient are present in one unit without being in admixture.

A non-fixed combination or "kit-of-parts" in the present invention is used as known to persons skilled in the art and is defined as a combination wherein a first active ingredient

and a further active ingredient are present in more than one unit. One example of a non-fixed combination or kit-of-parts is a combination wherein the first active ingredient and the further active ingredient are present separately. It is possible for the components of the non-fixed combination or kit-of-parts to be administered separately, sequentially, simultaneously, concurrently or chronologically staggered.

The compounds of the present invention can be administered as the sole pharmaceutical agent or in combination with one or more other pharmaceutically active ingredients where the combination causes no unacceptable adverse effects. The present invention also provides such pharmaceutical combinations. For example, the compounds of the present invention can be combined with known anti-cancer-agents, said anti-cancer agents including but not limited to:

Based upon standard laboratory techniques known to evaluate compounds useful for the treatment of hyperproliferative diseases, more particularly cancer diseases by standard toxicity tests and by standard pharmacological assays for the determination of treatment of the conditions identified above in mammals, and by comparison of these results with the results of known active ingredients or medicaments that are used to treat these conditions, the effective dosage of the compounds of the present invention can readily be determined for treatment of each desired indication. The amount of the active ingredient to be administered in the treatment of one of these conditions can vary widely 15 according to such considerations as the particular compound and dosage unit employed, the mode of administration, the period of treatment, the age and sex of the patient treated, and the nature and extent of the condition treated.

The total amount of the active ingredient to be administered will generally range from about 0.001 mg/kg to about 500 mg/kg body weight per day, particularly about 0.001 25 mg/kg to about 200 mg/kg body weight per day, and more particularly from about 0.01 mg/kg to about 50 mg/kg body weight per day. Clinically useful dosing schedules will range from one to three times a day dosing to once every four weeks dosing. In addition, it is possible for "drug holidays", in which a patient is not dosed with a drug for a certain period of time, to be beneficial to the overall balance between pharmacological effect and tolerability. It is possible for a unit dosage to contain from about 0.5 mg to about 1500 mg 30 of active ingredient, and can be administered one or more times per day or less than once a day. The average daily dosage for administration by injection, including intravenous, intramuscular, subcutaneous and parenteral injections, and use of infusion techniques will preferably be from 0.01 to 200 mg/kg of total body weight. The average daily rectal dosage regimen will preferably be from 0.01 to 200 mg/kg of total body 35 weight. The average daily vaginal dosage regimen will preferably be from 0.01 to 200

mg/kg of total body weight. The average daily topical dosage regimen will preferably be from 0.1 to 200 mg administered between one to four times daily. The transdermal concentration will preferably be that required to maintain a daily dose of from 0.01 to 200 mg/kg. The average daily inhalation dosage regimen will preferably be from 0.01 to 100 mg/kg of total body weight. For oral administration the dosing schedule maybe once or two time or three times daily and a dose range as referred to above for general dosing is possible.

Of course the specific initial and continuing dosage regimen for each patient will vary according to the nature and severity of the condition as determined by the attending diagnostician, the activity of the specific compound employed, the age and general condition of the patient, time of administration, route of administration, rate of excretion of the drug, drug combinations, and the like. The desired mode of treatment and number of doses of a compound of the present invention or a pharmaceutically acceptable salt or ester or composition thereof can be ascertained by those skilled in the art using conventional treatment tests.

## EXAMPLES

### EXPERIMENTAL SECTION

NMR peak forms are stated as they appear in the spectra, possible higher order effects have not been considered.

- 5 The  $^1\text{H}$ -NMR data of selected compounds are listed in the form of  $^1\text{H}$ -NMR peaklists. Therein, for each signal peak the  $\delta$  value in ppm is given, followed by the signal intensity, reported in round brackets. The  $\delta$  value-signal intensity pairs from different peaks are separated by commas. Therefore, a peaklist is described by the general form:  $\delta_1$  (intensity<sub>1</sub>),  $\delta_2$  (intensity<sub>2</sub>), ...,  $\delta_i$  (intensity<sub>i</sub>), ...,  $\delta_n$  (intensity<sub>n</sub>).
- 10 The intensity of a sharp signal correlates with the height (in cm) of the signal in a printed NMR spectrum. When compared with other signals, this data can be correlated to the real ratios of the signal intensities. In the case of broad signals, more than one peak, or the center of the signal along with their relative intensity, compared to the most intense signal displayed in the spectrum, are shown. A  $^1\text{H}$ -NMR peaklist is similar to a classical
- 15  $^1\text{H}$ -NMR readout, and thus usually contains all the peaks listed in a classical NMR interpretation. Moreover, similar to classical  $^1\text{H}$ -NMR printouts, peaklists can show solvent signals, signals derived from stereoisomers of the particular target compound, peaks of impurities,  $^{13}\text{C}$  satellite peaks, and/or spinning sidebands. The peaks of stereoisomers, and/or peaks of impurities are typically displayed with a lower intensity
- 20 compared to the peaks of the target compound (*e.g.*, with a purity of >90%). Such stereoisomers and/or impurities may be typical for the particular manufacturing process, and therefore their peaks may help to identify a reproduction of the manufacturing process on the basis of "by-product fingerprints". An expert who calculates the peaks of the target compound by known methods (MestReC, ACD simulation, or by use of
- 25 empirically evaluated expectation values), can isolate the peaks of the target compound as required, optionally using additional intensity filters. Such an operation would be similar to peak-picking in classical  $^1\text{H}$ -NMR interpretation. A detailed description of the reporting of NMR data in the form of peaklists can be found in the publication "Citation of NMR Peaklist Data within Patent Applications" (cf.
- 30 <http://www.researchdisclosure.com/searching-disclosures>, Research Disclosure Database Number 605005, 2014, 01 Aug 2014). In the peak picking routine, as described in the Research Disclosure Database Number 605005, the parameter "MinimumHeight" can be adjusted between 1% and 4%. However, depending on the chemical structure and/or depending on the concentration of the measured compound it
- 35 may be reasonable to set the parameter "MinimumHeight" <1%.

Chemical names were generated using the ACD/Name software from ACD/Labs. In some cases generally accepted names of commercially available reagents were used in place of ACD/Name generated names.

## 5 EXPERIMENTAL SECTION - GENERAL PART

All reagents, for which the synthesis is not described in the experimental part, are either commercially available, or are known compounds or may be formed from known compounds by known methods by a person skilled in the art.

The compounds and intermediates produced according to the methods of the invention may require purification. Purification of organic compounds is well known to the person skilled in the art and there may be several ways of purifying the same compound. In some cases, no purification may be necessary. In some cases, the compounds may be purified by crystallization. In some cases, impurities may be stirred out using a suitable solvent. In some cases, the compounds may be purified by chromatography, particularly flash column chromatography, using for example prepacked silica gel cartridges, e.g. Biotage SNAP cartridges KP-Sil® or KP-NH® in combination with a Biotage autopurifier system (SP4® or Isolera Four®) and eluents such as e.g. gradients of hexane/ethyl acetate or DCM/methanol. In some cases, the compounds may be purified by preparative HPLC using for example a Waters autopurifier equipped with a diode array

detector and/or on-line electrospray ionization mass spectrometer in combination with a suitable prepacked reverse phase column and eluents such as e.g. gradients of water and acetonitrile which may contain additives such as e.g. trifluoroacetic acid, formic acid or aqueous ammonia.

- 5 In some cases, purification methods as described above can provide those compounds of the present invention which possess a sufficiently basic or acidic functionality in the form of a salt, such as e.g., in the case of a compound of the present invention which is sufficiently basic, a trifluoroacetate or formate salt for example, or, in the case of a compound of the present invention which is sufficiently acidic, an ammonium salt for example. A salt of this type can either be transformed into its free base or free acid form, respectively, by various methods known to the person skilled in the art, or be used as salts in subsequent biological assays. It is to be understood that the specific form (e.g. salt, free base etc.) of a compound of the present invention as isolated and as described herein is not necessarily the only form in which said compound can be applied to a biological assay in order to quantify the specific biological activity.

## EXPERIMENTAL SECTION - GENERAL PROCEDURES

### *General details*

30 All reactions were carried out under nitrogen (N<sub>2</sub>) atmosphere. All reagents and solvents were purchased from commercial vendors and used as received. Nuclear magnetic resonance (NMR) spectra were recorded on a Bruker (300 or 400 MHz <sup>1</sup>H, 75 or 101 MHz <sup>13</sup>C) spectrometer. Proton and carbon chemical shifts are reported in ppm

( $\delta$ ) referenced to the NMR solvent. Data are reported as follows: chemical shifts, multiplicity (br = broad, s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet; coupling constant(s) in Hz). Flash chromatography was performed using 40-60  $\mu$ m Silica Gel (60 Å mesh) on a Teledyne Isco Combiflash Rf or a Biotage Isolera. Analytical thin layer chromatography (TLC) was performed on EM Reagent 0.25 mm silica gel 60-F plates.

#### **Example 119**

(rac)-5-(3-fluoro-4-morpholinophenyl)-6-methyl-3,6-dihydro-2H-1,3,4-oxadiazin-2-one

Following a literature procedure (J. Med. Chem. **1990**, 35, 163), to 370 mg of (rac)-1-(3-fluoro-4-morpholinophenyl)-2-hydroxypropan-1-one (1.46 mmol, Intermediate 33) in 4 mL

15

EtOH and 5-6 drops of 0.1 N HCl were added 131 mg (1.46 mmol) of methyl hydrazinecarboxylate and the reaction was heated at reflux 1 h. After cooling, the mixture was concentrated, and more EtOH followed by concentration was done twice to remove residual water and acid. To the crude mixture was added a NaOEt solution (350 mg of sodium consumed in 5 mL EtOH) and the mixture was stirred overnight. The next day the solid was filtered off and added to a mixture of slightly acidic (HCl) water and EtOAc. The EtOAc layer was separated, dried and concentrated to give 107 mg (25%) of product as an off-white solid.

## EXPERIMENTAL SECTION - BIOLOGICAL ASSAYS

Examples were tested in selected biological assays one or more times. When tested more than once, data are reported as either average values or as median values, wherein

- 5       · the average value, also referred to as the arithmetic mean value, represents the sum of the values obtained divided by the number of times tested, and
- the median value represents the middle number of the group of values when ranked in ascending or descending order. If the number of values in the data set is odd, the median is the middle value. If the number of values in the data set is
- 10       even, the median is the arithmetic mean of the two middle values.

Examples were synthesized one or more times. When synthesized more than once, data from biological assays represent average values or median values calculated utilizing data sets obtained from testing of one or more synthetic batch.

#### Cell proliferation measurement

The antiproliferative activity of the compounds of the general formula (I) was examined *in vitro* in human cancer cells. For this purpose, the appropriate number of cells (Hela: 800; SK-MEL-3: 1000; A549: 800) were plated in 384-well plates with appropriate growth medium ((A549: DMEM/Ham's F12 (Biochrom; # FG 4815 with stabile Glutamine), FCS 10% final (Biochrom; # S 0415); Hela: DMEM/Ham's F12 (Biochrom; # FG 4815 with stabile Glutamine), FCS 10% final (Biochrom; # S 0415); SK-MEL-3: McCoy's 5A (Biochrom; # F 1015), FCS 10% final (Biochrom; # S 0415), L-Alanyl-L-Glutamine final: 25       2mM, (Biochrom; # K 0302)) and incubated at 37°C overnight. After 24 h, cells on one plate (0 h plate) were treated with 30 µl/cavity of CTG solution (Promega Cell Titer Glo (catalogue # G755B and G756B)) and incubated at room temperature for 10 min, and luminescence was measured by means of a VICTOR V (Perkin Elmer), in order to determine cell viability on commencement of treatment. The cells on the test plate were

30       treated with the compounds of the general formula (I) as and incubated at 37°C for 72 h. The compounds were added to the cells by means of an HP D300 digital dispenser in a 10-step 2,5-fold dilution series generally starting at a maximum final drug concentration of 100nM. As control, the cells were treated with vehicle (DMSO at 0.3% final concentration). After 72 h, the cells were treated with 30 µl/cavity of CTG solution

(Promega Cell Titer Glo (catalogue # G755B and G756B)) and incubated at room temperature for 10 min, and luminescence was measured by means of a VICTOR V (Perkin Elmer), in order to determine cell viability at the end of treatment. The percentage effect on cell growth and the IC<sub>50</sub> derived therefrom were determined for each test substance using the values from the 0 h plate (= maximum inhibition) and the DMSO control (= minimum inhibition). The IC<sub>50</sub> values were calculated using a 4-parameter fit.

### Cell proliferation measurement

The antiproliferative activity of the compounds of the general formula (I) was examined *in vitro* in human cancer cells. For this purpose, 500 cells, including HeLa cells, A2058 cells, DU145 cells, HMCB cells, IGR37 cells, NCIH1734 cells, OSRC2 cells, or 750 cells, including CAL51 cells, COL0741 cells, DBTRG05MG cells, DKMG cells, G292CLONEA141 B1 cells, GB1 cells, HEL cells, HEL9217 cells, JHUEM1 cells, L3.3 cells, LI7 cells, TE4 cells, or 1000 cells, including 8505C cells, HUT78 cells, NCIH1563 cells, NCIH2122 cells, NCIH2172 cells, RVH421 cells, SKMEL3 cells, or 1500 cells, including C32 cells, HS578T cells, JHOM1 cells, NCIH196 cells, OVKATE cells, were plated in 384-well plates with appropriate growth medium and incubated at 37°C overnight. After 24 h, the cells on the test plate were treated with the compounds of the general formula (I) as and incubated at 37°C for 72 h. The compounds were added to the

cells by means of an HP D300 digital dispenser in a 10 (or more) -step dilution series. As control, the cells were treated with vehicle (DMSO at 0.3% final concentration). After 72 h, the cells were treated with 20  $\mu$ l/well of 50% CTG solution in PBS (Promega Cell Titer Glo (catalogue # G755B and G756B)) and incubated at room temperature for 10 min, and luminescence was measured by means of a VICTOR V (Perkin Elmer), in order to determine cell viability at the end of treatment. The percentage effect on cell growth and the  $IC_{50}$  derived therefrom were determined for each test substance using the values from untreated wells (= percent viability). The  $IC_{50}$  values were calculated using a 4-parameter fit.

#### In vivo xenotransplantation models

10 The anti-tumor activities of Compounds of examples 135 and 146 were examined in murine xenotransplantation models of human cancer. For this purpose, mice were implanted subcutaneously with tumor cells. At a mean tumor size of 20-40 mm<sup>2</sup> animals were randomized into treatment and control groups (at least n=10 animals/group) and treatment started with vehicle only or respective Compound (formulation: 90%  
15 PEG400/10% Ethanol; application route: per os ("p.o."), orally). The oral application volume was 10 ml/kg. In the case of twice daily treatments, the time interval between two applications per day was 6-7h. The tumor size and the body weight were determined at least weekly. The tumor area was detected by means of an electronic caliper [length (mm) x width (mm)]. The experiment was ended when the study reached the pre-  
20 determined ethical endpoint based on German and European animal welfare regulations. In vivo anti-tumor efficacy is presented as T/C ratio at study end (Treatment/Control; mean tumor weight of treatment group / mean tumor weight of control group) in Table 8. A compound having a T/C below 0.5 is defined as active (i.e., effective). Statistical analysis was assessed using SigmaStat software. A one-way analysis of variance was  
25 performed and differences to the control were compared by a pair-wise comparison procedure (Dunn's method).

Compounds of examples 135 and 146 showed potent anti-tumor efficacy in different xenograft models of human tumors upon monotherapy treatment. Specifically, Compound example 135 and/or example 146 were effective in reduction of tumor area in  
30 cervical cancer, ovarian teratocarcinoma, AML and melanoma.

##### Method for PDE3A enzyme inhibition

The commercially available 3H-cAMP Scintillation Proximity Assay (SPA, Perkin Elmer) system was used for enzyme inhibition studies. For the determination of the *in vitro* effect of example compounds on the PDE3A reactions 2  $\mu$ I of the respective example compound solution in DMSO (serial dilutions) were placed in wells of microtiter plates (Isoplate-96/200W; Perkin Elmer). 50  $\mu$ I of a dilution of PDE3A cell extract from Sf9 cells overexpressing human full length PDE3A (SB Drug Discovery, UK) in buffer A (50 mM Tris/HCl pH 7.5, 8.3 mM MgCl<sub>2</sub>, 1.7 mM EDTA, 0.2% BSA) was added. The dilution of the PDE3A cell extract was chosen such that the reaction kinetics was linear and less than 70% of the substrate was consumed (typical dilution 1:5000). The reaction was started by addition of 50  $\mu$ I (0.025  $\mu$ Ci) of 1:2000 in buffer A w/o BSA diluted

20

substrate [8-3H] adenosine 3', 5'-cyclic phosphate ( $1 \mu\text{Ci}/\mu\text{l}$ ; Perkin Elmer). After incubation at room temperature for 60 min, the reaction was stopped by addition of  $25 \mu\text{l}$  of a suspension containing 18 mg/ml yttrium scintillation proximity beads (Perkin Elmer) in water. The microtiter plates were sealed and measured in a Microbeta scintillation counter (PerkinElmer Wallac).  $\text{IC}_{50}$  values were determined from sigmoidal curves by plotting percentage PDE3A activity vs log compound concentration.

## Assay 5

### **PDE3B enzyme inhibition**

10 The commercially available 3H-cAMP Scintillation Proximity Assay (SPA, Perkin Elmer) system was used for enzyme inhibition studies. For the determination of the *in vitro* effect of example compounds on the PDE3B reactions  $2 \mu\text{l}$  of the respective example compound solution in DMSO (serial dilutions) were placed in wells of microtiter plates (Isoplate-96/200W; Perkin Elmer).  $50 \mu\text{l}$  of a dilution of PDE3B cell extract from  
15 Sf9 cells overexpressing human full length PDE3B (SB Drug Discovery, UK) in buffer A (50 mM Tris/HCl pH 7.5, 8.3 mM  $\text{MgCl}_2$ , 1.7 mM EDTA, 0.2% BSA) was added. The dilution of the PDE3B cell extract was chosen such that the reaction kinetics was linear and less than 70% of the substrate was consumed (typical dilution 1:6000). The reaction was started by addition of  $50 \mu\text{l}$  ( $0.025 \mu\text{Ci}$ ) of 1:2000 in buffer A w/o BSA diluted  
20 substrate [8-3H] adenosine 3', 5'-cyclic phosphate ( $1 \mu\text{Ci}/\mu\text{l}$ ; Perkin Elmer). After incubation at room temperature for 60 min, the reaction was stopped by addition of  $25 \mu\text{l}$  of a suspension containing 18 mg/ml yttrium scintillation proximity beads (Perkin Elmer) in water. The microtiter plates were sealed and measured in a Microbeta scintillation counter (PerkinElmer Wallac).  $\text{IC}_{50}$  values were determined from sigmoidal curves by  
25 plotting percentage PDE3B activity vs log compound concentration.

One aspect of the invention are compounds of formula (I) which effectively inhibit tumor cell proliferation with  $\text{IC}_{50}$  values of  $< 100 \text{ nM}$  in e.g. HeLa cells while  $\text{IC}_{50}$  values for enzymatic PDE3A or PDE3B inhibition are often  $> 2.5$  times higher than  $\text{IC}_{50}$  values for tumor cell proliferation.

30 Another aspect of the invention are compounds of formula (I) which effectively inhibit tumor cell proliferation with  $\text{IC}_{50}$  values of  $< 100 \text{ nM}$  in e.g. HeLa cells while  $\text{IC}_{50}$  values for enzymatic PDE3A or PDE3B inhibition are often  $> 10$  times higher than  $\text{IC}_{50}$  values for tumor cell proliferation.

One aspect of the invention are compounds of formula (I) which effectively inhibit  
35 tumor cell proliferation with  $\text{IC}_{50}$  values of  $< 100 \text{ nM}$  in e.g. HeLa cells while  $\text{IC}_{50}$  values

for enzymatic PDE3A or PDE3B inhibition are often > 30 times higher than  $IC_{50}$  values for tumor cell proliferation.

## Assay 6

### **Method for human cryo Hepatocytes:**

- Investigation of *in vitro* metabolic stability in cryopreserved human hepatocytes
- 5 (including calculation of hepatic *in vivo* blood clearance (CL) and maximal oral bioavailability (F<sub>max</sub>))

Cryopreserved Hepatocytes {e.g. purchased from Celsis InVitroTechnologies) were briefly thawed, washed with 45 mL pre-warmed in vitro GRO HT medium and centrifuged for 5 min at 50xg. The cell pellet was resuspended in 5 ml of Krebs-Henseleit Butter (KHB). Cell viability was determined by trypan blue exclusion.

- 5 For the metabolic stability assay liver cells were distributed in WME containing 5% FCS to glass vials at a density of  $1.0 \times 10^6$  vital cells/ml. The test compound was added to a final concentration of 1  $\mu$ M. During incubation, the hepatocyte suspensions were continuously shaken at 580 rpm and aliquots were taken at 2, 8, 16, 30, 45 and 90 min, to which equal volumes of cold methanol were immediately added. Samples were  
10 frozen at -20° C over night, after subsequently centrifuged for 15 minutes at 3000 rpm and the supernatant was analyzed with an Agilent 1290 HPLC-system with LCMS/MS detection.

The half-life of a test compound was determined from the concentration-time plot. From the half-life the intrinsic clearances were calculated. Together with the additional  
15 parameters liver blood flow, amount of liver cells in vivo and in vitro. The hepatic in vivo blood clearance (CL) and the maximal oral bioavailability (Fmax) was calculated. The hepatic in vivo blood clearance (CL<sub>blood</sub>) and the maximal oral bioavailability (Fmax) was calculated using the following formulae:  $CL_{intrinsic} [ml/(min \cdot kg)] = k_{el} [1/min] / ((cellno / volume \text{ of incubation } [ml]) \cdot f_{ujnc}) \cdot (cellno / liver \text{ weight } [g]) \cdot (specific \text{ liver weight } [g \text{ liver } / kg \text{ body weight}])$ ;  $CL_{blood \text{ well-stirred }} [L/(h \cdot kg)] = (QH [L/(h \cdot kg)] \cdot f_{u,blood} \cdot CL_{intrinsic} [L/(h \cdot kg)]) / (QH [L/(h \cdot kg)] + f_{u,blood} \cdot CL_{intrinsic} [L/(h \cdot kg)])$ ;  $F_{max} = 1 - CL_{blood} / QH$  and using the following parameter values: Liver blood flow - 1.32 L/h/kg human; specific liver weight - 2.1 g/kg body weight; liver cells in vivo-  $1.1 \times 10^8$  cells/g liver, liver cells in vitro -  $1.0 \times 10^6$ /ml.;  $f_{ujnc}$  and  $f_{u,blood}$  is taken as 1.

## Assay 7

### *In vivo pharmacokinetics in non-rodents (e.g. dogs)*

For *in vivo* pharmacokinetic experiments test compounds were administered to non-rodents (e.g. female Beagle dogs) intravenously (i.v.) at doses of 0.1 to 1 mg/kg and intragastrally (i.g.) at doses of 0.3 to 3 mg/kg formulated as solutions using solubilizers such as e.g. PEG400 in well-tolerated amounts and are usually given as short term infusion (15 min).

Blood samples were taken e.g. at 2 min, 8 min, 15 min, 30 min, 45 min, 1 h, 2 h, 4 h, 6 h, 8 h and 24 h after dosing from the vena saphena. Depending on the expected half-life additional samples were taken at later time points (e.g. 48 h, 72 h).

For pharmacokinetics after intragastral administration test compounds were given intragastrally to fasted non-rodents (e.g. dogs). Blood samples were taken e.g. at 5 min,

15 min, 30 min, 45 min, 1 h, 2 h, 4 h, 6 h, 8 h and 24 h after dosing. Depending on the expected half-life additional samples were taken at later time points (**e.g.** 48 h, 72 h). Blood was collected into Lithium-Heparin tubes (Monovetten®, Sarstedt) and centrifuged for 15 min at 3000 rpm. A small aliquot (**e.g.** 100  $\mu$ L) from the supernatant (plasma) was

5 taken and precipitated by addition of an aliquot ice cold acetonitrile (**e.g.** of 400  $\mu$ L) and frozen at -20 °C over night. Samples were subsequently thawed and centrifuged at 3000 rpm, 4°C for 20 minutes. Aliquots of the supernatants were taken for analytical testing using an Agilent HPLC-system with LCMS/MS detection. PK parameters were calculated by non-compartmental analysis using a PK calculation software.

10 PK parameters derived from concentration-time profiles after i.v.: CL<sub>plasma</sub>: Total plasma clearance of test compound (in L/kg/h); CL<sub>blood</sub>: Total blood clearance of test compound: CL<sub>plasma</sub>\*C<sub>p</sub>/C<sub>b</sub> (abbreviation: CL<sub>p</sub>; ) in L/kg/h) with C<sub>p</sub>/C<sub>b</sub> being the ratio of concentrations in plasma and blood.

PK parameters calculated from concentration time profiles after i.g.: C<sub>max</sub>: Maximal plasma concentration (in mg/L); C<sub>maxnorm</sub>: C<sub>max</sub> divided by the administered dose (in kg/L); T<sub>max</sub>: Time point at which C<sub>max</sub> was observed (in h). Parameters calculated from both, i.v. and i.g. concentration-time profiles: AUC<sub>norm</sub>: Area under the concentration-time curve from t=0h to infinity (extrapolated) divided by the administered dose (in kg\*h/L); AUC(0-t<sub>last</sub>)<sub>norm</sub>: Area under the concentration-time curve from t=0h to the last

20 time point for which plasma concentrations could be measured divided by the administered dose (in kg\*h/L); t<sub>1/2</sub>: terminal half-life (in h); F: oral bioavailability: AUC<sub>norm</sub> after intragastral administration divided by AUC<sub>norm</sub> after intravenous administration (in %).

## Assay 8

### *In vivo pharmacokinetics in rodents (e.g. mice)*

The housing and handling of animals was performed in strict compliance with the European and German Guidelines for Laboratory Animal Welfare. Animals received food and water ad libitum. For the quantification of circulating compounds in plasma, a certain  
5 dose (1 - 100 mg/kg) was orally administered to female NMRI<sup>nu/nu</sup> mice at the age of 6-8 weeks in a solubilized form (n=3 mice per time point).

Blood was collected into Lithium-Heparin tubes (Monovetten®, Sarstedt) and centrifuged for 15 min at 3000 rpm. A small aliquot (e.g. 100 µL) from the supernatant (plasma) was  
10 taken and precipitated by addition of an aliquot ice cold acetonitrile (e.g. of 400 µL) and frozen at -20 °C over night. Samples were subsequently thawed and centrifuged at 3000 rpm, 4°C for 20 minutes. Aliquots of the supernatants were taken for analytical testing using an Agilent HPLC-system with LCMS/MS detection. PK parameters were calculated by non-compartmental analysis using a PK calculation software.

## Assay 9

### *Validation of PDE3A modulator-induced PDE3A protein interactions using immunoprecipitation and immunoblotting*

HeLa cells were transfected with ORF overexpression constructs expressing V5-tagged SLFN12, or V5-tagged GFP. ORF expression constructs were obtained from the  
20 TRC (clone IDs: TRCN0000468231, TRCN0000476272, ccsbBroad304\_99997). At 72 hours post transfection, cells were treated with 10 µM DNMDP or trequinsin for 4 hours followed by lysis using the ModRipa lysis buffer and immunoprecipitation of PDE3A. For each condition, 2 mg total protein lysate was incubated with 1 µg of anti-PDE3A antibody  
25 at 4°C overnight, after which 7.5 µL each of Protein A- and Protein G- Dynabeads (Life Technologies 10001 D and 10003D) were added and incubated for another 1 hour. Beads were washed and bound proteins were eluted with 30 µL of LDS PAGE gel loading buffer. Input (~60 µg total protein lysate) and IP products were resolved on 4-12% Tris-Glycine PAGE gels and immunoblotted with an anti-V5 antibody (Life Technologies  
30 R96205, 1:5000), the Bethyl anti-PDE3A antibody (1:1000), and secondary antibodies from LiCOR Biosciences (Cat.# 926-32210 and 926068021, each at 1:10,000). Blots were washed and imaged using a LiCOR Odyssey infrared imager.
