Title: COMPOSITIONS OF AN ANTIHYPERTENSIVE AND AN ANTIULCERATIVE DRUG FOR AFFECTING WEIGHT LOSS

Abstract: Disclosed are compositions for affecting weight loss comprising a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is an antiulcerative. Also disclosed are methods of affecting weight loss, including energy expenditure, increasing satiety in an individual, or suppressing the appetite of an individual, comprising identifying an individual in need thereof and treating that individual with a psychotherapeutic agent and an antiulcerative.
COMPOSITIONS OF AN ANTICONVULSANT AND AN ANTIPSYCHOTIC DRUG AND METHODS OF USING THE SAME FOR AFFECTING WEIGHT LOSS

Related Application

Background of the Invention

Field of the Invention

[0002] The present invention is in the field of pharmaceutical compositions and methods for the treatment of obesity and for affecting weight loss in individuals.

Description of the Related Art

[0003] Obesity is a disorder characterized by the accumulation of excess fat in the body. Obesity has been recognized as one of the leading causes of disease and is emerging as a global problem. Increased instances of complications such as hypertension, non-insulin dependent diabetes mellitus, arteriosclerosis, dyslipidemia, certain forms of cancer, spondylosis, and osteoarthritis have been related to increased instances of obesity in the general population.

[0004] Obesity has been defined in terms of body mass index (BMI). BMI is calculated as weight (kg)/[Height (m)]^2. According to the guidelines of the U.S. Centers for Disease Control and Prevention (CDC), and the World Health Organization (WHO) (World Health Organization. Physical status: The use and interpretation of anthropometry. Geneva,
Switzerland: World Health Organization 1995. *WHO Technical Report Series*, for adults over 20 years old, BMI falls into one of these categories: below 18.5 is considered underweight, 18.5 – 24.9 is considered normal, 25.0 – 29.9 is considered overweight, and 30.0 and above is considered obese.

Prior to 1994, obesity was generally considered a psychological problem. The discovery of the adipocrine hormone leptin in 1994 (Zhang et al., “Positional cloning of the mouse obese gene and its human homologue,” Nature 1994; 372:425-432) brought forth the realization that, in certain cases, obesity may have a biochemical basis. A corollary to this realization was the idea that the treatment of obesity may be achieved by chemical approaches. Since then, a number of such chemical treatments have entered the market. The most famous of these attempts was the introduction of Fen-Phen, a combination of fenfluramine and phentermine. Unfortunately, it was discovered that fenfluramine caused heart-valve complications, which in some cases resulted in the death of the user. Fenfluramine has since been withdrawn from the market. There has been some limited success with other combination therapy approaches, particularly in the field of psychological eating disorders. One such example is Devlin, et al., *Int. J. Eating Disord.* 28:325-332, 2000, in which a combination of phentermine and fluoxetine showed some efficacy in the treatment of binge eating disorders. Of course, this disorder is an issue for only a small portion of the population.

In addition to those individuals who satisfy a strict definition of medical obesity, a significant portion of the adult population is overweight. These overweight individuals would also benefit from the availability of an effective weight-loss composition. Therefore, there is an unmet need in the art to provide pharmaceutical compositions that can affect weight loss without having other adverse side effects.

**Summary of the Invention**

Disclosed are compositions for affecting weight loss comprising a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is an anticonvulsant.

Disclosed are also methods of reducing the risk of weight gain associated with the use of antidepressants or other antipsychotic drugs.

**Detailed Description of the Preferred Embodiment**

Newer generation antidepressants seem less likely to be associated with cardiovascular side effects and toxicity associated with older generation antidepressants,
such as tricyclic antidepressants or monoamine oxidase inhibitors (MAOIs). Currently, newer generation antidepressants include selective serotonin reuptake inhibitors (e.g., fluoxetine, fluvoxamine, sertraline, paroxetine, citalopram, and escitalopram), venlafaxine, duloxetine, nefazodone, mianserin, setipipine, vispamline trazodone, cianopramine, and mirtazapine. Weight gain has been a major concern with certain of the newer antidepressants, particularly, with paroxetine (PAXIL®, PAXIL CR®) and mirtazapine (Fava, J. Clin. Psychiat. 61 (suppl. 11):37-41 (2000); Carpenter et al, J. Clin. Psych. 60:45-49 (1999); Aroune et al, J. Clin. Psych. 64 (suppl. 8):22-29 (2003), both of which are incorporated by reference herein in their entirety). A large proportion of patients treated with paroxetine, mirtazapine, and other antidepressants, such as venlafaxine (EFFEXOR®, EFFEXOR XR®), gain a significant amount of weight. Most of these patients find it difficult to lose the weight gained as a result of treatment, even after discontinuing use of the particular antidepressant. Weight gain is unacceptable in patients and a major reason for noncompliance with antidepressant therapy (Cash et al, Percep. Motor Skills 90:453-456 (2000); Deshmukh et al, Cleveland Clinic J. Med. 70:614-618 (2003), both of which are incorporated by reference herein in their entirety). Without being bound by any particular theory, it is believed that potential mechanisms for the observed weight gain include histamine H1 receptor antagonism for mirtazapine, and anticholinergic effects in the case of paroxetine.

Zonisamide is a marketed anticonvulsant indicated as adjunctive therapy for adults with partial onset seizures. Without being bound by any particular theory, it is believed that the mechanism of antiepileptic activity appears to be: 1) sodium-channel blocking; and, 2) reduction of inward T-type calcium currents. In addition, zonisamide binds to the GABA/benzodiazepine receptor complex without producing change in chloride flux. Further, zonisamide facilitates serotoninergic and dopaminergic neurotransmission and possesses a weak inhibitory effect on carbonic anhydrase.

Zonisamide has been shown to cause significant weight loss (comparable to marketed weight loss medications) in patients presenting with primary obesity (Giddie et al, JAMA. 289:1820-1825 (2003), incorporated by reference herein in its entirety). It has been postulated that it is the effect of zonisamide on the CNS concentration of serotonin, dopamine and carbonic anhydrase that is responsible for this effect. There is evidence that zonisamide increases serotonin and dopamine synthesis rates (Hashiguti et al, J Neural Transm Gen Sect. 1993;93:213-223; Otada et al, Epilepsy Res. 1992;13:113-119, both of
which are incorporated by reference herein in their entirety). There is further evidence suggesting that zonisamide stimulates dopamine D2 receptors (Okada et al, Epilepsy Res. 1995;22:193-205, incorporated by reference herein in its entirety). Zonisamide was well tolerated, fatigue being the only side effect that occurred more frequently than with placebo treatment.

[0012] Thus, the present inventors have determined that the use of anticonvulsants in general is effective in reducing or preventing the weight gain associated with the use of medications such as antidepressants, particularly newer generation of antidepressants, antihistamines, and serotonin receptor antagonists, such as 5HT2C receptor antagonists.

[0013] Aspects of the present invention provide, at least in part, methods of reducing the risk of weight gain associated with antidepressant therapy. These methods involve the use of weight-loss promoting anticonvulsants. The methods of the present invention are also effective against individuals who have gained weight irrespective of the use of antidepressants.

[0014] Thus, in a first aspect, the present invention is directed to a composition for the treatment of obesity or for affecting weight loss comprising a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is an anticonvulsant.

[0015] In certain embodiments, the anticonvulsant is effective in reducing convulsions in a mammal. The mammal may be selected from the group consisting of mice, rats, rabbits, guinea pigs, dogs, cats, sheep, goats, cows, primates, such as monkeys, chimpanzees, and apes, and humans.

[0016] In some embodiments the psychotherapeutic agent is an antidepressant, an antimigraine, an antidepressant, an antimania drug, a mood stabilizer, or an antiepileptic. Examples of antidepressants include paroxetine and mirtazapine. Examples of antimigraine drugs include sumatriptan, zolmitriptan, eletriptan and other triptans. Examples of antiepileptic drugs include lithium, valproate, carbamazepine, oxcarbamazepine, lamotrigine, tiagabine, olanzapine, clozapine, risperidone, quetiapine, aripiprazole, ziprasidone, and benzodiazepines. In some embodiments, the psychotherapeutic agent comprises a salt of lithium. In other embodiments, the psychotherapeutic agent is valproate, which includes both the salt of valproate and the free acid form of valproic acid. Also included are pharmaceutically acceptable salts or prodrugs of these drugs, extended
release formulations of the above drugs, as well as combinations of the above drugs. In some embodiments, the lithium salt may be lithium carbonate or lithium citrate. In some embodiments, the lithium drug is in an extended release formulation.

[0017] In some embodiments, the present invention is directed to compositions comprising zonisamide and a salt of lithium, as described herein and in formulations described herein. In other embodiments, the present invention is directed to compositions comprising zonisamide and valproic acid, or a pharmaceutically acceptable salt, such as different salts of valproic acid, ester, amide, or prodrugs thereof.

[0018] In certain embodiments, the antidepressant is a compound of Formula I

![Chemical Structure](image)

where

W is nitrogen, CH, oxygen, or sulfur;

R₁ is selected from the group consisting of hydrogen, optionally substituted C₁₋₄ alkyl, optionally substituted C₅₋₁₄ cycloalkyl, optionally substituted C₂₋₄ alkynyl, optionally substituted C₂₋₄ alkenyl, optionally substituted C₅₋₁₄ alkynyl, optionally substituted C₅₋₁₄ alkoxyalkyl, and optionally substituted aryl and aralkyl;

R₂, R₃, R₄ and R₅ are each independently selected from the group consisting of hydrogen, halogen, optionally substituted C₁₋₄ alkyl, optionally substituted C₁₋₄ alkoxy, optionally substituted C₂₋₄ alkenyl, optionally substituted C₂₋₄ alkynyl, optionally substituted C₁₋₄ alkoxyalkyl, optionally substituted C₁₋₄ alkylthio, perhaloalkyl, CN, COR₁₀, CONHR₁₀, heteroalkyl, and NO₂;

R₆, R₇, R₈ and R₉ are each independently selected from the group consisting of hydrogen, halogen, optionally substituted C₁₋₄ alkyl, optionally substituted C₁₋₄ alkoxy, optionally substituted C₂₋₄ alkenyl, optionally substituted C₂₋₄ alkynyl, optionally substituted C₁₋₄ alkoxyalkyl, optionally substituted C₁₋₄ alkylthio, perhaloalkyl, CN, COR₁₀, CONHR₁₀, heteroalkyl, and NO₂.

[0019] The term “pharmaceutically acceptable salt” refers to a formulation of a compound that does not cause significant irritation to an organism to which it is
administered and does not abrogate the biological activity and properties of the compound.

Pharmaceutical salts can be obtained by reacting a compound of the invention with inorganic acids such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid, methanesulfonic acid, ethanesulfonic acid, p-toluene sulfonic acid, salicylic acid and the like. Pharmaceutical salts can also be obtained by reacting a compound of the invention with a base to form a salt such as an ammonium salt, an alkali metal salt, such as a sodium or a potassium salt, an alkaline earth metal salt, such as a calcium or a magnesium salt, a salt of organic bases such as dicyclohexylamine, N-methyl-D-glucamine, tri(p-hydroxyethyl)methylammonium, and salts thereof with amino acids such as arginine, lysine, and the like.

A "prodrug" refers to an agent that is converted into the parent drug in vivo. Prodrugs are often useful because, in some situations, they may be easier to administer than the parent drug. They may, for instance, be bioavailable by oral administration whereas the parent is not. The prodrug may also have improved solubility in pharmaceutical compositions over the parent drug, or may demonstrate increased palatability or be easier to formulate. An example, without limitation, of a prodrug would be a compound of the present invention which is administered as an ester (the "prodrug") to facilitate transmittal across a cell membrane where water solubility is detrimental to mobility but which then is metabolically hydrolyzed to the carboxylic acid, the active entity, once inside the cell where water-solubility is beneficial. A further example of a prodrug might be a short peptide (polyaminoacid) bonded to an acid group where the peptide is metabolized to provide the active moiety.

In another embodiment, the antidepressant is a tricyclic antidepressant. Examples of tricyclic antidepressants include, but are not limited to, imipramine, desipramine, trimipramine, nortriptyline, clomipramine, doxepin, amitriptyline, maprotiline, protriptyline, dothiapram, setipramine, cianopramine, and maprotiline. Maprotiline, a very effective antidepressant, is not used widely because it carries risk of seizures. The combination of maprotiline and zonisamide or other anticonvulsants has the added benefit of reducing the risk of seizures, in addition to reducing the risk of weight gain due to the use of the antidepressant. The same is also true for combining zonisamide with clomipramine, another tricyclic associated with a relatively higher risk of seizures.

In further embodiments, the antidepressant is a monoamine oxidase inhibitor (MAO inhibitor). Examples of MAO inhibitors include, but are not limited to,
phenelzine (Nardil®), tranylcypromine (Parnate®), isoconazole (Miurplan®), moclobemide (Aurorix®), brofaromine, cinomoxone, clorgyline, and lazabemide.

[0023] In certain embodiments, the antihistamine is one of scopolamine, tecpiptine, ORG 8282 (Organon, Netherlands), or MO 8282 (Mochida, Japan).

[0024] In some embodiments, the 5HT₂C receptor antagonist is selected from colozapine, N-desmethylcolozapine, and clozapine-N-oxide.

[0025] In some embodiments, the second compound is an anticonvulsant. Examples of anticonvulsants include barbiturates, benzodiazepines, GABA analogues, hydantoins, miscellaneous anticonvulsants, phenyltriazines, and succinimides. An example of a barbiturate includes pentobarbital. Examples of benzodiazepines include clonazepam, clorazepate, benzodiazepine, and diazepam. Examples of GABA analogues include tiagabine, pregabalin, and gabapentin. Examples of hydantoins include fosphenytoin, phenytoin, and 5,5-Diphenylhydantoin. Examples of miscellaneous anticonvulsants include carbamazepine, valproate, valproic acid, divalproex, felbamate, levetiracetam, carbamazepine, topiramate, oxcarbazepine, and zonisamide. An example of a phenyltriazine is lamotrigine. Examples of succinimides include methsuximide and ethosuximide. Also included are extended release formulations of the above drugs, pharmaceutically acceptable salts or prodrugs thereof, as well as combinations of the above drugs.

[0026] In one embodiment, the present invention is directed to a composition for the treatment of obesity or for affecting weight loss comprising zonisamide and mirtazapine. In another embodiment, the present invention is directed to a composition for the treatment of obesity or for affecting weight loss comprising zonisamide and paroxetine. In yet another embodiment, the present invention is directed to a composition for the treatment of obesity or for affecting weight loss comprising zonisamide and venlafaxine.

[0027] In certain embodiments, the present invention is directed to a composition for affecting weight loss or for preventing weight gain comprising zonisamide and mirtazapine. In other embodiments, the present invention is directed to a composition for affecting weight loss or for preventing weight gain comprising bupropion and mirtazapine. In further embodiments, the present invention is directed to a composition for affecting weight loss or for preventing weight gain comprising zonisamide and sotipilazine. In other embodiments, the present invention is directed to a composition for affecting weight loss or for preventing weight gain comprising bupropion and sotipilazine. In
additional embodiments, the present invention is directed to a composition for affecting weight loss or for preventing weight gain comprising zonisamide, bupropion, and mirtazapine. In yet other embodiments, the present invention is directed to a composition for affecting weight loss or for preventing weight gain comprising zonisamide, bupropion, and scopolamine.

[0028] Throughout the present disclosure, when a particular compound is mentioned by name, for example, zonisamide, bupropion, scopolamine, mirtazapine, or valproate, it is understood that the scope of the present disclosure encompasses pharmaceutically acceptable salts, esters, amides, or prodrugs of the named compound. Also, if the named compound comprises a chiral center, the scope of the present disclosure also includes compositions comprising the racemic mixture of the two enantiomers, as well as compositions comprising each enantiomer individually substantially free of the other enantiomer. Thus, for example, contemplated herein is a composition comprising the S enantiomer substantially free of the R enantiomer, or a composition comprising the R enantiomer substantially free of the S enantiomer. By “substantially free” it is meant that the composition comprises less than 10%, or less than 5%, or less than 3%, or less than 1% of the minor enantiomer. If the named compound comprises more than one chiral center, the scope of the present disclosure also includes compositions comprising a mixture of the various diastereomers, as well as compositions comprising each diastereomer substantially free of the other diastereomers. Thus, for example, commercially available mirtazapine is a racemic mixture comprising two separate enantiomers. The recitation of “mirtazapine” throughout this disclosure includes compositions that comprise the racemic mixture of mirtazapine, the compositions that comprise the (+) enantiomer substantially free of the (-) enantiomer, and the compositions that comprise the (-) enantiomer substantially free of the (+) enantiomer.

[0029] In another aspect, the present invention relates to a method of affecting weight loss, comprising identifying an individual in need thereof and treating that individual with a psychotherapeutic agent and an anticonvulsant. The psychotherapeutic agent and the anticonvulsant are as described above.

[0030] In certain embodiments, the individual has a body mass index (BMI) greater than 25. In other embodiments, the individual has a BMI greater than 30. In still other embodiments, the individual has a BMI greater than 40. However, in some embodiments, the individual may have a BMI less than 25. In some of those embodiments,
it may be beneficial for health or cosmetic purposes to affect weight loss, thereby reducing the BMI even further. In some embodiments, the individual has reached the above BMI as the result of antidepressant therapy. In other embodiments, the individual has reached the above BMI without the use of antidepressants.

[0031] In some embodiments, the treating step of the above method comprises administering to the individual a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is a anticonvulsant.

[0032] In some embodiments the first compound and the second compound are administered more or less simultaneously. In other embodiments the first compound is administered prior to the second compound. In yet other embodiments, the first compound is administered subsequent to the second compound.

[0033] In certain embodiments, the first compound and the second compound are administered individually. In other embodiments, the first compound and the second compound are covalently linked to each other such that they form a single chemical entity. The single chemical entity is then digested and is metabolized into two separate physiologically active chemical entities; one of which is the first compound and the other one is the second compound.

[0034] In certain embodiments, the first compound is zonisamide and the second compound is mirtazapine. In other embodiments, the first compound is bupropion and the second compound is mirtazapine. In further embodiments, the first compound is zonisamide and the second compound is setiptilnine. In other embodiments, the first compound is bupropion and the second compound is setiptilnine. In additional embodiments, the first compound is a combination of zonisamide and bupropion and the second compound is mirtazapine. In yet other embodiments, the first compound is a combination of zonisamide and bupropion and the second compound is setiptilnine.

[0035] In some embodiments, the first compound is zonisamide and the second compound is a salt of lithium, as described herein and in formulations described herein. In other embodiments, the first compound is zonisamide and the second compound is valproic acid, or a pharmaceutically acceptable salt, such as different salts of valproate, ester, amide, or prodrugs thereof.

[0036] In some embodiments, the first compound is topiramate and the second compound is a salt of lithium, as described herein and in formulations described herein. In other embodiments, the first compound is topiramate and the second compound is valproic acid, or a pharmaceutically acceptable salt, such as different salts of valproate, ester, amide, or prodrugs thereof.
acid, or a pharmaceutically acceptable salt, such as different salts of valproate, ester, amide, or prodrug thereof.

[0037] In another aspect, the present invention relates to a method of increasing satiety in an individual comprising identifying an individual in need thereof and treating that individual with a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is an anticonvulsant.

[0038] In some embodiments the first compound and the second compound are administered nearly simultaneously. In other embodiments the first compound is administered prior to the second compound. In yet other embodiments, the first compound is administered subsequent to the second compound.

[0039] In yet another aspect, the present invention relates to a method of suppressing the appetite of an individual comprising identifying an individual in need thereof and treating that individual by administering to the individual a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is an anticonvulsant.

[0040] In some embodiments the first compound and the second compound are administered nearly simultaneously. In other embodiments the first compound is administered prior to the second compound. In yet other embodiments, the first compound is administered subsequent to the second compound.

[0041] In certain embodiments, the first compound is zonisamide and the second compound is mirtazapine. In other embodiments, the first compound is bupropion and the second compound is mirtazapine. In further embodiments, the first compound is zonisamide and the second compound is setiptiline. In other embodiments, the first compound is bupropion and the second compound is setiptiline. In additional embodiments, the first compound is a combination of zonisamide and bupropion and the second compound is mirtazapine. In yet other embodiments, the first compound is a combination of zonisamide and bupropion and the second compound is setiptiline.

[0042] In another aspect, the present invention relates to a method of increasing energy expenditure in an individual comprising identifying an individual in need thereof and treating that individual by administering to the individual a first compound and a second compound, where the first compound is a psychotherapeutic agent and the second compound is an anticonvulsant.
In some embodiments the first compound and the second compound are administered nearly simultaneously. In other embodiments the first compound is administered prior to the second compound. In yet other embodiments, the first compound is administered subsequent to the second compound.

In certain embodiments disclosed herein, an individual is given a pharmaceutical composition comprising a combination of two or more compounds to affect weight loss. In some of these embodiments, each compound is a separate chemical entity. However, in other embodiments, the two compounds are joined together by a chemical linkage, such as a covalent bond, so that the two different compounds form separate parts of the same molecule. The chemical linkage is selected such that after entry into the body, the linkage is broken, such as by enzymatic action, acid hydrolysis, base hydrolysis, or the like, and the two separate compounds are then formed.

Aspects of the present invention also relate to methods of reducing the risk of weight gain associated with the administration of antidepressants, antihistamines, or serotonin receptor antagonists. Other aspects of the invention further relate to methods of minimizing metabolic risk factors associated with weight gain, such as hypertension, diabetes and dyslipidaemia. In one embodiment, the methods comprise administering to a mammal receiving an antidepressant an amount of zonisamide, or other weight-loss promoting anticonvulsant, sufficient to reduce the weight gain risk associated with the antidepressant. In an alternative embodiment, the methods comprise administering to mammal receiving an antidepressant a combination of zonisamide or topiramate, or other weight-loss promoting anticonvulsant (including agents that block kainate/AMPA (D,L-alpha-amino-3-hydroxy-5-methyl-isoxazolepropionic acid) subtype glutamate receptors), and bupropion, or other compound that enhances the activity of norepinephrine and/or dopamine via uptake inhibition or other mechanism, in an amount sufficient to reduce the weight gain risk associated with the antidepressant.

In certain embodiments, methods of the present invention are directed to reducing the risk of weight gain in an individual who already is on antidepressant therapy, or is about to begin antidepressant therapy. In these embodiments, in addition to the antidepressant, the individual is administered a composition comprising an anticonvulsant and a psychotherapeutic drug, as described herein, where the psychotherapeutic drug is not an antidepressant. Thus, in some embodiments, the individual who is taking mirtazapine or setipiline is administered a composition comprising zonisamide or a composition
comprising zonisamide and bupropion. In other embodiments, the individual who is taking mirtazapine or setipiline is administered a composition comprising zonisamide or a composition comprising zonisamide and valproate. In further embodiments, the individual who is taking mirtazapine or setipiline is administered a composition comprising zonisamide or a composition comprising zonisamide and venlafaxine.

[0047] In certain embodiments, the weight gain risk-reducing agents for use in the methods of the present invention include zonisamide or topiramate (and pharmaceutically acceptable salts thereof). In other embodiments, other methanesulfonamide derivatives, such as those described in U.S. Patent 4,172,896, or other sulfamates (including sulfamate-substituted monosaccharides), such as those described in U.S. Patent 4,513,006, incorporated by reference herein in its entirety, are used.

[0048] In further embodiments, the weight gain risk-reducing agent is bupropion; while in other embodiments, compounds disclosed in U.S. Patent 3,819,706 and 3,885,046, both of which are incorporated by reference herein in their entirety, are used. In additional embodiments, the weight gain risk-reducing agent is a compound that enhances the activity of norepinephrine and/or dopamine, such as by reuptake inhibition or other mechanism. All of the above-mentioned U.S. patents are.

[0049] Compounds that enhance the activity of norepinephrine and/or dopamine include norepinephrine agonists, such as phenyltrimetacrine and benphentamine; norepinephrine reuptake inhibitors such as atomoxetine, bupropion, radafaxine, thionoxetine, and reboxetine; dopamine agonists, such as cabergoline, amantadine, lisuride, pergolide, ropinirole, pramipexole, and bromocriptine; norepinephrine releasers, for example diethylpropion; a mixed dopamine/norepinephrine reuptake inhibitor, for example, bupropion; a combination of a dopamine reuptake inhibitor and a norepinephrine reuptake inhibitor, e.g., bupropion and marindol; or a combination of a selective serotonin reuptake inhibitor (SSRI) and a norepinephrine reuptake inhibitor, such as sibutramine, venlafaxine, and duloxetine.

[0050] Mammals suitable for treatment in accordance with the instant invention can be receiving any antidepressant associated with weight gain. Typically, however, the antidepressant is a newer generation antidepressant (e.g., a selective serotonin uptake inhibitor (e.g., fluoxetine, fluvoxamine, sertraline, paroxetine, citalopram, and escitalopram), venlafaxine, nefazodone, and mirtazapine), particularly, paroxetine or mirtazapine.
The amount of weight gain risk-reducing agent(s) administered in the pharmaceutical compositions described herein can vary with the patient, the antidepressant that the patient is receiving, the route of administration and the result sought. Optimum dosing regimen for particular patients can be readily determined by one skilled in the art.

In accordance with the invention, the combination of, for example, zonisamide or topiramate and bupropion (including sustained release preparations) provides an effective means of minimizing metabolic risks associated with weight gain and/or antidepressant use (e.g., type II diabetes). The combination can be more effective than, for example, zonisamide or topiramate treatment alone and with fewer side effects. Neuropharmacologically, all three major nerve transmitters that regulate appetite and weight, i.e., serotonin, norepinephrine and dopamine, are targeted with the combination of, for example, bupropion and zonisamide or topiramate. Side effects of, for example, zonisamide or topiramate (such as somnolence, psychomotor slowing, cognitive impairment, fatigue and depression) can be offset by insomnia, activation, psychomotor agitation and antidepressant effects of, for example, bupropion. On the other hand, zonisamide or topiramate, for example, can reduce the seizure risk associated with, for example, bupropion. Lower doses of both types of medication can be used in the combination treatment, thereby further reducing the overall side effect burden.

With regard to the pharmacokinetics of zonisamide, its renal excretion and minimal potential for inhibition or induction of hepatic microsomal enzymes, are favorable qualities in the concept of combination use with antidepressants, particularly newer generation antidepressants.

In another aspect, the invention relates to a pharmaceutical composition comprising a combination of a psychotherapeutic agent and an anticonvulsant, as described above, or comprising a linked molecule, as described herein, and a physiologically acceptable carrier, diluent, or excipient, or a combination thereof.

Details of some embodiments of the appropriate routes of administration and compositions suitable for same can be found in, for example, U.S. Patent Nos. 6,110,973, 5,763,493, 5,731,000, 5,541,231, 5,427,798, 5,358,970 and 4,172,896, as well as in patents cited therein, all of which are incorporated by reference herein in their entirety, including any drawings.

The term “pharmaceutical composition" refers to a mixture of a compound of the invention with other chemical components, such as diluents or carriers.
The pharmaceutical composition facilitates administration of the compound to an organism. Multiple techniques of administering a compound exist in the art including, but not limited to, oral, injection, aerosol, parenteral, and topical administration. Pharmaceutical compositions can also be obtained by reacting compounds with inorganic or organic acids such as hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid, methanesulfonic acid, ethanesulfonic acid, p-toluene sulfonic acid, salicylic acid and the like.

[0057] The term “carrier” defines a chemical compound that facilitates the incorporation of a compound into cells or tissues. For example dimethyl sulfoxide (DMSO) is a commonly utilized carrier as it facilitates the uptake of many organic compounds into the cells or tissues of an organism.

[0058] The term “diluent” defines chemical compounds diluted in water that will dissolve the compound of interest as well as stabilize the biologically active form of the compound. Salts dissolved in buffered solutions are utilized as diluents in the art. One commonly used buffered solution is phosphate buffered saline because it mimics the salt conditions of human blood. Since buffer salts can control the pH of a solution at low concentrations, a buffered diluent rarely modifies the biological activity of a compound.

[0059] The term “physiologically acceptable” defines a carrier or diluent that does not abrogate the biological activity and properties of the compound.

[0060] The pharmaceutical compositions described herein can be administered to a human patient per se, or in pharmaceutical compositions where they are mixed with other active ingredients, as in combination therapy, or suitable carriers or excipient(s). Techniques for formulation and administration of the compounds of the instant application may be found in “Remington’s Pharmaceutical Sciences,” Mack Publishing Co., Easton, PA, 18th edition, 1990.

[0061] Suitable routes of administration may, for example, include oral, rectal, transmucosal, or intestinal administration; parenteral delivery, including intramuscular, subcutaneous, intravenous, intramedullary injections, as well as intrathecal, direct intraventricular, intraperitoneal, intranasal, or intraocular injections.

[0062] Alternatively, one may administer the compound in a local rather than systemic manner, for example, via injection of the compound directly in the renal or cardiac area, often in a depot or sustained release formulation. Furthermore, one may administer the drug in a targeted drug delivery system, for example, in a liposome coated with a
tissue-specific antibody. The liposomes will be targeted to and taken up selectively by the organ.

[0063] The pharmaceutical compositions of the present invention may be manufactured in a manner that is itself known, e.g., by means of conventional mixing, dissolving, granulating, dragee-making, levigating, emulsifying, encapsulating, entrapping or tabletting processes.

[0064] Pharmaceutical compositions for use in accordance with the present invention thus may be formulated in conventional manner using one or more physiologically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically. Proper formulation is dependent upon the route of administration chosen. Any of the well-known techniques, carriers, and excipients may be used as suitable and as understood in the art; e.g., in Remington’s Pharmaceutical Sciences, above.

[0065] For injection, the agents of the invention may be formulated in aqueous solutions, preferably in physiologically compatible buffers such as Hanks’s solution, Ringer’s solution, or physiological saline buffer. For transmucosal administration, penetrants appropriate to the barrier to be permeated are used in the formulation. Such penetrants are generally known in the art.

[0066] For oral administration, the compounds can be formulated readily by combining the active compounds with pharmaceutically acceptable carriers well known in the art. Such carriers enable the compounds of the invention to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions and the like, for oral ingestion by a patient to be treated. Pharmaceutical preparations for oral use can be obtained by mixing one or more solid excipient with pharmaceutical combination of the invention, optionally grinding the resulting mixture, and processing the mixture of granules, after adding suitable auxiliaries, if desired, to obtain tablets or dragee cores. Suitable excipients are, in particular, fillers such as sugars, including lactose, sucrose, mannitol, or sorbitol; cellulose preparations such as, for example, maize starch, wheat starch, rice starch, potato starch, gelatin, gum tragacanth, methyl cellulose, hydroxypropylmethyl-cellulose, sodium carboxymethylcellulose, and/or polyvinylpyrrolidone (PVP). If desired, disintegrating agents may be added, such as the cross-linked polyvinyl pyrrolidone, agar, or alginic acid or a salt thereof such as sodium alginate.
Dragee cores are provided with suitable coatings. For this purpose, concentrated sugar solutions may be used, which may optionally contain gum arabic, talc, polyvinyl pyrrolidone, carbopol gel, polyethylene glycol, and/or titanium dioxide, lacquer solutions, and suitable organic solvents or solvent mixtures. Dyestuffs or pigments may be added to the tablets or dragee coatings for identification or to characterize different combinations of active compound doses.

Pharmaceutical preparations which can be used orally, including sublingually, which include include push-fit capsules made of gelatin, as well as soft, sealed capsules made of gelatin and a plasticizer, such as glycerol or sorbitol. The push-fit capsules can contain the active ingredients in admixture with filler such as lactose, binders such as starches, and/or lubricants such as talc or magnesium stearate and, optionally, stabilizers. In soft capsules, the active compounds may be dissolved or suspended in suitable liquids, such as fatty oils, liquid paraffin, or liquid polyethylene glycols. In addition, stabilizers may be added. All formulations for oral administration should be in dosages suitable for such administration.

For buccal administration, the compositions may take the form of tablets or lozenges formulated in conventional manner.

For administration by inhalation, the compounds for use according to the present invention are conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebulizer, with the use of a suitable propellant, e.g., dichlorodifluoromethane, dichlorotetrafluoroethane, carbon dioxide, or other suitable gas. In the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of, e.g., gelatin for use in an inhaler or insufflator may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

The compounds may be formulated for parenteral administration by injection, e.g., by bolus injection or continuous infusion. Formulations for injection may be presented in unit dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain further agents such as suspending, stabilizing and/or dispersing agents.

Pharmaceutical formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form. Additionally,
suspensions of the active compounds may be prepared as appropriate oily injection suspensions. Suitable lipophilic solvents or vehicles include fatty oils such as sesame oil, or synthetic fatty acid esters, such as ethyl oleate or triglycerides, or liposomes. Aqueous injection suspensions may contain substances which increase the viscosity of the suspension, such as sodium carboxymethyl cellulose, sorbitol, or dextran. Optionally, the suspension may also contain suitable stabilizers or agents which increase the solubility of the compounds to allow for the preparation of highly concentrated solutions.

[0073] Alternatively, the active ingredient may be in powder form for coadministration with a suitable vehicle, e.g., sterile pyrogen-free water, before use.

[0074] The compounds may also be formulated in rectal compositions such as suppositories or retention enemas, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

[0075] In addition to the formulations described previously, the compounds may also be formulated as a depot preparation. Such long acting formulations may be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compounds may be formulated with suitable polymeric or hydrophobic materials (for example as an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

[0076] A pharmaceutical carrier for the hydrophobic compounds of the invention is a cosolvent system comprising benzyl alcohol, a nonpolar surfactant, a water-miscible organic polymer, and an aqueous phase. A common cosolvent system used is the VPD co-solvent system, which is a solution of 3% v/w benzyl alcohol, 8% v/w of the nonpolar surfactant Polysorbate 80® and 65% w/v polyethylene glycol 300, made up to volume in absolute ethanol. Naturally, the proportions of a co-solvent system may be varied considerably without destroying its solubility and toxicity characteristics. Furthermore, the identity of the co-solvent components may be varied: for example, other low-toxicity nonpolar surfactants may be used instead of POLYSORBATE 80®; the fraction size of polyethylene glycol may be varied; other bio compatible polymers may replace polyethylene glycol, e.g., polyvinyl pyrrolidone; and other sugars or polysaccharides may substitute for dextrose.

[0077] Alternatively, other delivery systems for hydrophobic pharmaceutical compounds may be employed. Liposomes and emulsions are well known examples of
delivery vehicles or carriers for hydrophobic drugs. Certain organic solvents such as dimethylsulfoxide also may be employed, although usually at the cost of greater toxicity. Additionally, the compounds may be delivered using a sustained-release system, such as semipermeable matrices of solid hydrophobic polymers containing the therapeutic agent. Various sustained-release materials have been established and are well known by those skilled in the art. Sustained-release capsules may, depending on their chemical nature, release the compounds for a few weeks up to over 100 days. Depending on the chemical nature and the biological stability of the therapeutic reagent, additional strategies for protein stabilization may be employed.

[0078] Many of the compounds used in the pharmaceutical combinations of the invention may be provided as salts with pharmaceutically compatible counterners. Pharmaceutically compatible salts may be formed with many acids, including but not limited to hydrochloric, sulfuric, acetic, lactic, tartaric, malic, succinic, etc. Salts tend to be more soluble in aqueous or other protonic solvents than are the corresponding free acid or base forms.

[0079] Pharmaceutical compositions suitable for use in the present invention include compositions where the active ingredients are contained in an amount effective to achieve its intended purpose. More specifically, a therapeutically effective amount means an amount of compound effective to prevent, alleviate or ameliorate symptoms of disease or prolong the survival of the subject being treated. Determination of a therapeutically effective amount is well within the capability of those skilled in the art, especially in light of the detailed disclosure provided herein.

[0080] The exact formulation, route of administration and dosage for the pharmaceutical compositions of the present invention can be chosen by the individual physician in view of the patient's condition. (See e.g., Fingl et al. 1975, in “The Pharmacological Basis of Therapeutics”, Ch. 1 p. 1). Typically, the dose range of the composition administered to the patient can be from about 0.5 to 100 mg/kg of the patient’s body weight. The dosage may be a single one or a series of two or more given in the course of one or more days, as is needed by the patient. Note that for almost all of the specific compounds mentioned in the present disclosure, human dosages for treatment of at least some condition have been established. Thus, in most instances, the present invention will use those same dosages, or dosages that are between about 0.1% and 500%, more preferably between about 25% and 250% of the established human dosage. Where no
human dosage is established, as will be the case for newly-discovered pharmaceutical compounds, a suitable human dosage can be inferred from ED$_{50}$ or ID$_{50}$ values, or other appropriate values derived from in vitro or in vivo studies, as qualified by toxicity studies and efficacy studies in animals.

[0081] Although the exact dosage will be determined on a drug-by-drug basis, in most cases, some generalizations regarding the dosage can be made. The daily dosage regimen for an adult human patient may be, for example, an oral dose of between 0.1 mg and 6000 mg of each ingredient, preferably between 1 mg and 5000 mg, e.g. 25 to 5000 mg or an intravenous, subcutaneous, or intramuscular dose of each ingredient between 0.01 mg and 100 mg, preferably between 0.1 mg and 60 mg, e.g. 1 to 40 mg of each ingredient of the pharmaceutical compositions of the present invention or a pharmaceutically acceptable salt thereof calculated as the free base, the composition being administered 1 to 4 times per day. Alternatively the compositions of the invention may be administered by continuous intravenous infusion, preferably at a dose of each ingredient up to 400 mg per day. Thus, the total daily dosage by oral administration of each ingredient will typically be in the range 1 to 2500 mg and the total daily dosage by parenteral administration will typically be in the range 0.1 to 400 mg. Suitably the compounds will be administered for a period of continuous therapy, for example for a week or more, or for months or years.

[0082] In some embodiments, the dosage range for lithium carbonate, for an oral dose, will result in blood levels of lithium being between about 0.5 and about 1.5 meq/l. In a preferred embodiment, the lithium carbonate dosage range, for an oral dose, will be about 900 mg/day.

[0083] In certain embodiments, the dosage range for valproate, for an oral dose, is in the range of about 250 to about 5000 mg/day. In a preferred embodiment, the valproate dosage range, for an oral dose, will be about 1500 mg/day.

[0084] In further embodiments, the dosage range for zonisamide, for an oral dose, is in the range of about 25 to about 600 mg per day. In some embodiments, the dosage is 25 mg per day. In other embodiments, the dosage is 50 mg per day. In yet other embodiments, the dosage is 100 mg per day.

[0085] In further embodiments, the dosage range for mitrazapine, for an oral dose, is in the range of about 5 to about 500 mg per day. In some embodiments, the dosage is 8 mg per day. In other embodiments, the dosage is 16 mg per day. In yet other embodiments, the dosage is 32 mg per day. In some embodiments, the dosage is 15 mg per
day. In other embodiments, the dosage is 30 mg per day. In yet other embodiments, the dosage is 45 mg per day.

[0086] In other embodiments, the dosage range for venlafaxine venlafaxin XR, for an oral dose, is in the range of about 20 mg to about 600 mg per day. In some embodiments, the dosage is 25 mg per day. In other embodiments, the dosage is 37.5 mg per day. In yet other embodiments, the dosage is 50 mg per day. In some embodiments, the dosage is 75 mg per day. In other embodiments, the dosage is 100 mg per day. In yet other embodiments, the dosage is 150 mg per day.

[0087] Dosage amount and interval may be adjusted individually to provide plasma levels of the active moiety which are sufficient to maintain the modulating effects, or minimal effective concentration (MEC). The MEC will vary for each compound but can be estimated from in vitro data. Dosages necessary to achieve the MEC will depend on individual characteristics and route of administration. However, HPLC assays or bioassays can be used to determine plasma concentrations.

[0088] Dosage intervals can also be determined using MEC values. Compositions should be administered using a regimen that maintains plasma levels above the MEC for 90-90% of the time, preferably between 90-90% and most preferably between 50-90%.

[0089] In cases of local administration or selective uptake, the effective local concentration of the drug may not be related to plasma concentration.

[0090] The amount of composition administered will, of course, be dependent on the subject being treated, on the subject’s weight, the severity of the affliction, the manner of administration and the judgment of the prescribing physician.

[0091] The compositions may, if desired, be presented in a pack or dispenser device which may contain one or more unit dosage forms containing the active ingredient. The pack may for example comprise metal or plastic foil, such as a blister pack. The pack or dispenser device may be accompanied by instructions for administration. The pack or dispenser may also be accompanied with a notice associated with the container in form prescribed by a governmental agency regulating the manufacture, use, or sale of pharmaceuticals, which notice is reflective of approval by the agency of the form of the drug for human or veterinary administration. Such notice, for example, may be the labeling approved by the U.S. Food and Drug Administration for prescription drugs, or the approved product insert. Compositions comprising a compound of the invention formulated in a
compatible pharmaceutical carrier may also be prepared, placed in an appropriate container, and labeled for treatment of an indicated condition.

[0092] It will be understood by those of skill in the art that numerous and various modifications can be made without departing from the spirit of the present invention. Therefore, it should be clearly understood that the forms of the present invention are illustrative only and are not intended to limit the scope of the present invention.

[0093] All documents and other information sources cited above are hereby incorporated in their entirety by reference, as are Gadde et al., Obesity Res. 9:544-551 (2001) and Gadde et al., JAMA 289:1820-1825 (2003).

Some Embodiments of the Invention

[0094] Some of the embodiments of the present invention are as follows:

[0095] In the first embodiment, the invention relates to a composition for affecting weight loss comprising a first compound and a second compound, wherein said first compound is a psychotherapeutic agent and said second compound is an anticonvulsant.

[0096] In the second embodiment, the invention relates to the composition of the first embodiment, wherein said psychotherapeutic agent is selected from the group consisting of lithium carbonate, lithium citrate, valproate, mixtures thereof, and pharmaceutically acceptable salts or prodrugs thereof.

[0097] In the third embodiment, the invention relates to the composition of the first embodiment, wherein said second compound is selected from the group consisting of a barbiturate, benzodiazepine, GABA analogue, hydantoins, anticonvulsant, phenytoin, triazine, succinimide, pharmaceutically acceptable salts or prodrugs thereof, and combinations thereof.

[0098] In the fourth embodiment, the invention relates to the composition of the third embodiment, wherein said barbiturate is pentobarbital or pharmaceutically acceptable salts or prodrugs thereof.

[0099] In the fifth embodiment, the invention relates to the composition of the third embodiment, wherein said benzodiazepine is selected from the group consisting of clonazepam, alprazolam, chlordiazepoxide, lorazepam, diazepam, halazepam, lorazepam, oxazepam, prazepam, flurazepam, temazepam, triazolam, pharmaceutically acceptable salts or prodrugs thereof, and combinations thereof.
In the sixth embodiment, the invention relates to the composition of the third embodiment, wherein said GABA analogue is selected from the group consisting of tiagabine, gabapentin, pregabalin, pharmaceutically acceptable salts or prodrugs thereof, and combinations thereof.

In the seventh embodiment, the invention relates to the composition of the third embodiment, wherein said hydantoïne is selected from the group consisting of fosphenytoïne, phenytoïne, 5,5-Diphenylhydantoin, pharmaceutically acceptable salts or prodrugs thereof, and combinations thereof.

In the eighth embodiment, the invention relates to the composition of the third embodiment, wherein said miscellaneous anticonvulsant is selected from the group consisting of carbamazepine, valproate, valproic acid, divalproex, felbamate, levetiracem, carbamazepine, topiramate, oxcarbazepine, zonisamide, pharmaceutically acceptable salts or prodrugs thereof, and combinations thereof.

In the ninth embodiment, the invention relates to the composition of the third embodiment, wherein said phenyltiniracin is lamotrigine.

In the tenth embodiment, the invention relates to the composition of the third embodiment, wherein said succinimid is selected from the group consisting of meloxaminide, ethosuximid, and combinations thereof.

In the eleventh embodiment, the invention relates to the composition of the first embodiment, wherein said first compound is a psychotherapeutic agent and said second compound is a zonisamide.

In the twelfth embodiment, the invention relates to the composition of the first embodiment, wherein said first compound is lithium carbonate or lithium citrate and said second compound is zonisamide.

In the thirteenth embodiment, the invention relates to the composition of the first embodiment, wherein said first compound is valproate and said second compound is zonisamide.

In the fourteenth embodiment, the invention relates to the composition of the twelfth or thirteenth embodiment, wherein the zonisamide is in a time-release formulation.

In the fifteenth embodiment, the invention relates to a method of affecting weight loss, comprising identifying an individual in need thereof and treating that individual with a psychotherapeutic agent and an anticonvulsant.

-22-

-25-
[0110] In the sixteenth embodiment, the invention relates to the method of the fifteenth embodiment, wherein said individual has a body mass index greater than 25.

[0111] In the seventeenth embodiment, the invention relates to the method of the fifteenth embodiment, wherein the psychotherapeutic agent is selected from the group consisting of lithium carbonate, lithium citrate, and valproate, extended release formulations of the above drugs, and combinations of the above drugs.

[0112] In the eighteenth embodiment, the invention relates to the method of the fifteenth embodiment, wherein the anticonvulsant is selected from the group consisting of barbiturates, benzodiazepines, GABA analogues, hydantoins phenytoins, and succinimides, and pharmaceutically acceptable salts or prodrugs thereof.

[0113] In the nineteenth embodiment, the invention relates to the method of the fifteenth embodiment, wherein the anticonvulsant is selected from the group consisting of phenobarbital, clonazepam, clonazepate, benzodiazepine, diazepam, tiagabine, gabapentin, pregabalin, fosphenytoin, phenytoin, phenytoin, 5,5-Diphenylhydantoin, carbamazepine, valproate, valproic acid, divalproex, felbamate, levetiracetam, carbamazepine, topiramate, oxcarbazepine, zonisamide, lamotrigine, ethosuximide, ethosuximide, extended release formulations of the above drugs, and combinations of the above drugs.

[0114] In the twentieth embodiment, the invention relates to the method of the fifteenth embodiment, wherein said first compound and said second compound are administered nearly simultaneously.

[0115] In the twenty first embodiment, the invention relates to the method of the fifteenth embodiment, wherein said first compound is administered prior to said second compound.

[0116] In the twenty second embodiment, the invention relates to the method of the fifteenth embodiment, wherein said first compound is administered subsequent to said second compound.

[0117] In the twenty third embodiment, the invention relates to a method of increasing safety in an individual comprising identifying an individual in need thereof and treating that individual with a first compound and a second compound, wherein said first compound is a psychotherapeutic agent and said second compound is a anticonvulsant.

[0118] In the twenty fourth embodiment, the invention relates to the method of the twenty third embodiment, wherein said first compound and said second compound are administered nearly simultaneously.
[0119] In the twenty fifth embodiment, the invention relates to the method of the twenty third embodiment, wherein said first compound is administered prior to said second compound.

[0120] In the twenty sixth embodiment, the invention relates to the method of the twenty third embodiment, wherein said first compound is administered subsequent to said second compound.

[0121] In the twenty seventh embodiment, the invention relates to a method of increasing energy expenditure in an individual comprising identifying an individual in need thereof and treating that individual with a first compound and a second compound, wherein said first compound is a psychotherapeutic agent and said second compound is an anticonvulsant.

[0122] In the twenty eighth embodiment, the invention relates to the method of the twenty seventh embodiment, wherein said first compound and said second compound are administered nearly simultaneously.

[0123] In the twenty ninth embodiment, the invention relates to the method of the twenty seventh embodiment, wherein said first compound is administered prior to said second compound.

[0124] In the thirtieth embodiment, the invention relates to the method of the twenty seventh embodiment, wherein said first compound is administered subsequent to said second compound.

[0125] In the thirty first embodiment, the invention relates to a method of suppressing the appetite of an individual comprising identifying an individual in need thereof and treating that individual with a first compound and a second compound, wherein said first compound is a psychotherapeutic agent and said second compound is an anticonvulsant.

[0126] In the thirty second embodiment, the invention relates to the method of the thirty first embodiment, wherein said first compound and said second compound are administered nearly simultaneously.

[0127] In the thirty third embodiment, the invention relates to the method of the thirty first embodiment, wherein said first compound is administered prior to said second compound.
In the thirty fourth embodiment, the invention relates to the method of
the thirty first embodiment, wherein said first compound is administered subsequent to said
second compound.

In the thirty fifth embodiment, the invention relates to a method of
affecting weight loss in an individual comprising identifying an individual in need thereof
and treating that individual with a combination of lithium carbonate and zonisamide.

In the thirty sixth embodiment, the invention relates to a method of
affecting weight loss in an individual comprising identifying an individual in need thereof
and treating that individual with a combination of valproate and zonisamide.

In the thirty seventh embodiment, the invention relates to the method of
the thirty fifth or thirty sixth embodiments, wherein the individual has a BMI greater than
30.

In the thirty eighth embodiment, the invention relates to the method of
the thirty fifth or thirty sixth embodiments, wherein the individual has a BMI greater than
25.

In the thirty ninth embodiment, the invention relates to the method of the
thirty fifth or thirty sixth embodiments, wherein the lithium carbonate or valproate is in a
time-release formulation.

In the fortieth embodiment, the invention relates to the method of the
thirty fifth or thirty sixth embodiments, wherein the plasma concentration level of both the
lithium carbonate or valproate and zonisamide follow a similar concentration profile.

In the forty first embodiment, the invention relates to the method of the
thirty ninth embodiment, wherein the lithium carbonate or valproate and the zonisamide are
administered substantially simultaneously.

In the forty second embodiment, the invention relates to the method of
the thirty ninth embodiment, wherein the lithium carbonate or valproate is administered
prior to the zonisamide.

In the forty third embodiment, the invention relates to the method of the
thirty ninth embodiment, wherein the lithium carbonate or valproate is administered
subsequent to the zonisamide.

Examples

The examples below are non-limiting and are merely representative of
various aspects of the invention.
Example 1: Use of zonisamide alone:

[0139] Individuals taking an antidepressant, or about to take an antidepressant, who have gained weight as the result of the use of the antidepressant, or are susceptible to gain weight as the result of the use of the antidepressant, are identified. Each individual is instructed to take one 25 mg tablet of zonisamide on a daily basis, in addition to the antidepressant therapy.

[0140] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual’s particular needs.

[0141] The dosage of zonisamide can be from about 25 mg to about 800 mg per day, generally given once per day or divided (e.g., equally) into multiple doses. Preferably, the dose is from about 100 mg to about 600 mg per day, more preferably, the dose is from about 200 mg to about 400 mg per day. However, it may be necessary to use dosages outside these ranges. Zonisamide tablets are usually made and marketed in 25 mg, 50 mg, and 100 mg doses. Individual tablets, or combination of tablets can be used to achieve the desired dosing.

Example 2: Use of topiramate alone:

[0142] Individuals taking an antidepressant, or about to take an antidepressant, who have gained weight as the result of the use of the antidepressant, or are susceptible to gain weight as the result of the use of the antidepressant, are identified. Each individual is instructed to take one 25 mg tablet of topiramate on a daily basis, in addition to the antidepressant therapy.

[0143] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual’s particular needs.

[0144] The dosage of topiramate can be from about 25 mg to about 1600 mg, preferably from about 50 mg to about 600 mg, more preferably from about 100 mg to about 400 mg. However, it may be necessary to use dosages outside these ranges.

Example 3: Combination of zonisamide and mitrazapine:

[0145] Individuals having a BMI of greater than 25 are identified. Each individual is instructed to take one tablet of zonisamide on a daily basis, in addition to one
tablet of mitrazepine on a daily basis. Initially, the drugs are administered as follows: 8 mg mitrazepine and 64 mg zonisamide; or 16 mg mitrazepine and 128 mg zonisamide; or 32 mg mitrazepine and 252 mg zonisamide; generally with an mitrazepine/zonisamide ratio of 1:8.

[0146] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual’s particular needs.

[0147] If the initial dosages are not effective, they can be increased.

Example 4: Combination of zonisamide and paroxetine:

[0148] Individuals having a BMI of greater than 25 are identified. Each individual is instructed to take one tablet of zonisamide on a daily basis, in addition to one tablet of paroxetine on a daily basis. Initially, the drugs are administered as follows: 10 mg paroxetine and 60 mg zonisamide; or 20 mg paroxetine and 120 mg zonisamide; or 30 mg paroxetine and 180 mg zonisamide; or 40 mg paroxetine and 240 mg zonisamide; generally with a paroxetine/zonisamide ratio of 1:6.

[0149] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual’s particular needs.

[0150] If the initial dosages are not effective, they can be increased.

Example 5: Combination of zonisamide and lithium carbonate:

[0151] Individuals having a BMI of greater than 25 are identified. Each individual is instructed to take one 25 mg tablet of zonisamide on a daily basis, in addition to one 300 mg tablet of lithium carbonate on a daily basis.

[0152] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual’s particular needs.

[0153] If the initial dosage is not effective, then the zonisamide dosage can be increased by approximately 25 mg per day. If the initial dosage results in a more rapid weight loss than the above rate, the dosage of each of zonisamide or lithium carbonate can be reduced.
In some cases, it is beneficial to administer one dose ofzonisamide per
day in conjunction with two or three or more doses of lithium carbonate throughout the day.
Lithium carbonate may also be in a time-release formulation where the dose is administered
once a day, but lithium carbonate gradually enters the blood stream throughout the day, or
in the course of a 12 hour period.

The above procedure can be followed using lithium citrate, or any other
pharmaceutically acceptable salt of lithium, instead of lithium carbonate.

Example 6: Combination of zonisamide and lithium carbonate:

Individuals having a BMI of greater than 25 are identified. Each
individual is instructed to take one 25 mg tablet of zonisamide on a daily basis. In addition,
each individual is instructed to take one 300 mg tablet of lithium carbonate on a daily basis.

The individuals are monitored for a period of months. It is
recommended that the dosage be adjusted so that each individual loses weight at a rate of
10% of initial weight every 6 months. However, the rate of weight loss for each individual
may be adjusted by the treating physician based on the individual's particular needs. It is
recommended that serum creatinine be checked periodically.

If the initial dosage is not effective, then the lithium carbonate dosage
can be increased so as to achieve blood levels of 0.5 to 1.5 meq/l. If the initial dosage
results in a more rapid weight loss than the above rate, the dosage of each of zonisamide or
lithium carbonate can be reduced.

The above procedure can be followed using lithium citrate, or any other
pharmaceutically acceptable salt of lithium, instead of lithium carbonate.

Example 7: Combination of zonisamide and valproate:

Individuals having a BMI of greater than 25 are identified. Each
individual is instructed to take one 50 mg tablet of zonisamide on a daily basis, in addition
to one 500 mg tablet of valproate on a daily basis.

The individuals are monitored for a period of months. It is
recommended that the dosage be adjusted so that each individual loses weight at a rate of
10% of initial weight every 6 months. However, the rate of weight loss for each individual
may be adjusted by the treating physician based on the individual's particular needs.

If the initial dosage is not effective, then the zonisamide dosage can be
increased by approximately 30 mg per day, though not exceeding 600 mg total per day. If
the initial dosage results in a more rapid weight loss than the above rate, the dosage of each of zonisamide or valproate can be reduced.

[0163] In some cases, it is beneficial to administer one dose of zonisamide per day in conjunction with two or three or more doses of valproate throughout the day. Valproate may also be in a time-release formulation where the dose is administered once a day, but valproate gradually enters the bloodstream throughout the day, or in the course of a 12 hour period.

[Example 8: Combination of zonisamide and valproate]

[0164] Individuals having a BMI of greater than 25 are identified. Each individual is instructed to take one 50 mg tablet of zonisamide on a daily basis. In addition, each individual is instructed to take one 250 mg tablet of valproate on a daily basis.

[0165] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual's particular needs.

[0166] If the initial dosage is not effective, then the valproate dosage can be increased by 20 mg intervals up to 3000 mg per day. If the initial dosage results in a more rapid weight loss than the above rate, the dosage of each of zonisamide or valproate can be reduced.

[Example 9: Combination of zonisamide and olanzapine]

[0167] Individuals having a BMI of greater than 25 are identified. Each individual is instructed to take one tablet of zonisamide on a daily basis, in addition to one tablet of olanzapine on a daily basis. Initially, the drugs are administered as follows: 5 mg olanzapine and 60 mg zonisamide, or 10 mg olanzapine and 120 mg zonisamide; generally with an olanzapine/zonisamide ratio of 1:12.

[0168] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual's particular needs.

[0169] If the initial dosages are not effective, they can be increased.

[Example 10: Combination of zonisamide and risperidone]

[0170] Individuals having a BMI of greater than 25 are identified. Each individual is instructed to take one tablet of zonisamide on a daily basis, in addition tablet
of risperidone on a daily basis. Initially, the drugs are administered as follows: 0.5 mg risperidone and 30 mg zonisamide, 1 mg risperidone and 60 mg zonisamide, or 2 mg risperidone and 120 mg zonisamide; generally with an olanzapine/zonisamide ratio of 1:60.

[0071] The individuals are monitored for a period of months. It is recommended that the dosage be adjusted so that each individual loses weight at a rate of 10% of initial weight every 6 months. However, the rate of weight loss for each individual may be adjusted by the treating physician based on the individual’s particular needs.

[0072] If the initial dosages are not effective, they can be increased.

Example 11: Zonisamide and/or Bupropion prevent the weight gain associated with Mirtazapine or Setiptiline treatment.

Background

[0073] Mirtazapine shows considerable promise as a therapy for sleep apnea, but it causes weight gain in some patients. This weight gain limits the use of mirtazapine as a therapy for sleep apnea or as an antidepressant. Addition of zonisamide, or bupropion, or zonisamide plus bupropion, to concomitant mirtazapine treatment decreases the weight gain associated with mirtazapine, in a rodent model of mirtazapine-induced weight gain.

[0074] The melanocortin system controls energy balance. Mirtazapine and setiptiline change the activity of melanocortin circuits. Zonisamide, or bupropion, or zonisamide plus bupropion reverse this change in neuronal activity.

[0075] The melanocortin system consists of Proopiomelanocortin (POMC) neurons, the cognate melanocortin receptors (MC4 R) and the agouti-related peptide neurons in the arcuate nucleus of the hypothalamus. It is well established in humans and animals that the melanocortin system controls energy balance and the most common genetic cause of obesity in humans is congenital lack of MC4 R.

[0076] It has recently been shown that many compounds that influence energy balance modify the activity of melanocortin circuits. In particular, it has been shown that bupropion and zonisamide increase the electrophysiological activity of POMC neurons. As part of this research some of the receptors that can regulate the activity of POMC neurons have been identified; specifically it has been shown that 5-HT2C and 5-HT1B receptors increase the activity of POMC neurons as does dopamine D2 R. The clear role of 5-HT2CR in regulating the activity of POMC neurons suggests that compounds like mirtazapine,
which is an antagonist at this receptor, modify energy balance to induce an anabolic state, favoring weight gain.

**In vivo pharmacology**

[0177] We have developed a model to pre-clinically test the effects of mirtazapine on body weight gain. Dose-ranging studies are performed to determine the dose that best demonstrates the weight gain caused by mirtazapine or by setiptiline in the "rat-weight gain assay". Zonisamide, or bupropion, or zonisamide plus bupropion are tested to decrease the weight gain seen in response to concomitant mirtazapine or setiptiline therapy. Initially, a dose of 30mg/kg of zonisamide (bid) is used, but the dose in the experiment ranges from 20 mg/kg to 90 mg/kg (bid). Bupropion is used initially at a dose of 150 mg/kg/day, the dose in the experiment ranges from 50-190 mg/kg/day. Mirtazapine or setiptiline are used as solutions in minipumps. The concentration of the solution ranges between 0.1 μM to 10 mM. In some experiments, the concentration is calculated to provide a dose of about 1 mg/kg/day. In certain experiments, the concentration is 10 μM.

[0178] In a 4X3 design rats receive implants that acerate mirtazapine, or setiptiline, or vehicle. Some rats also receive co-treatment with saline, some receive zonisamide, some receive bupropion, and others receive co-treatment with zonisamide plus bupropion. In this way cohorts of 10 rats receive all possible combinations of the weight loss drug(s) with mirtazapine or setiptiline.

**Electrophysiology**

[0179] The electrophysiological response of POMC neurons to mirtazapine and to setiptiline is determined. It is then determined if co-treatment with zonisamide, or bupropion, or zonisamide plus bupropion prevents the expected decrease in POMC activity due to mirtazapine or setiptiline.

[0180] Preliminary data show that sub-threshold doses of zonisamide and bupropion synergistically inhibit acute food intake in mice, which is further evidence of
powerful synergy between zonisamide and bupropion to inhibit food intake in mice after a 16 hr fast.

[0181] In other preclinical experiments it has been shown that zonisamide and bupropion each inhibit food intake. These effects had faded by 4 hours, but the combination was effective when each compound alone was ineffective. The weight reducing effects of zonisamide and bupropion have also been well demonstrated in humans (Gadde et al, 2003; Gadde et al, 2001).

[0182] It has also been shown that zonisamide in combination with bupropion strongly increases the electrophysiological activity of POMC neurons in brain slices from POMC-EGFP mice. It has been shown that a large increase in rate of spontaneous action potentials in POMC neurons would be expected to stimulate significant secretion of α-MSH from POMC neurons, and consequent activation of MC4R — to inhibit food intake and decrease body weight gain.

Procedures
In vivo pharmacology

[0183] Female Sprague-Dawley rats weighing about 300 grams at the start of the experiment are used. Under isoflurane anesthesia, Alzet osmotic minipumps (2mL) are implanted subcutaneously between the shoulder blades. The rats are returned to their home cages after recovery. The minipumps deliver 5 μL per hour for 14 days. A range of doses of mirtazapine (from 0.1 to 20mg/kg/day dissolved in DMSO/saline) are used. Animals are housed individually and supplied with standard laboratory chow. Food consumed and animal weights are recorded every 3 days, to minimize disruption of the animals.

[0184] We have already shown in mice that bupropion, zonisamide, and zonisamide plus bupropion have pronounced effects on food intake after intra-peritoneal injection. We will develop chronic infusion methods to test the effects of bupropion, or zonisamide and zonisamide plus bupropion on weight gain over 14 days using the following groups:

[0185] 7 groups of 6 rats (6 doses of mirtazapine (0.1, 0.5, 1, 5, 10, 20 mg/kg), + saline)

[0186] The doses of zonisamide, and bupropion, and zonisamide plus bupropion that cause weight loss in this rat model in the preliminary studies are determined; the co-treatment experiments (mirtazapine plus zonisamide plus bupropion) are then performed.
Electrophysiology

[0187] The electrophysiological activity of Proopiomelanocortin (POMC) neurons in brain slices from POMC-EGFP mice are recorded. The POMC neurons in these mice are identified by the expression of green fluorescent protein (EGFP) in these, and only these, cells. The frequency of action potentials in these neurons are recorded using standard electrophysiological techniques. In particular, loose cell attached patch configuration is used to determine action potential frequency, whilst minimally disturbing the cells.

[0188] It has been shown that zonisamide, or bupropion, or zonisamide plus bupropion increase the activity of POMC neurons. The basal activity is recorded, and then mirtazapine or sertraline is added to the tissue bath to determine the effect of the antidepressant on the activity of POMC neurons. If mirtazapine or sertraline inhibits the activity of POMC neurons, the increase in neuronal activity by treating the brain slices with bupropion, or zonisamide or zonisamide plus bupropion is tested.

Example 11: Zonisamide plus bupropion prevent the weight gain associated with olanzapine treatment.

Background

[0189] In this experiment, the effect of co-treatment with drug combinations on the weight gain associated with olanzapine use is tested. Specifically, addition of zonisamide or zonisamide plus bupropion to concomitant olanzapine treatment is shown to decrease the weight gain associated with olanzapine, in a validated rodent model of olanzapine-induced weight gain.

[0190] The melanocortin system consists of Proopiomelanocortin (POMC) neurons, the cognate melanocortin receptors (MC4 R) and the agouti-related peptide neurons in the arcuate nucleus of the hypothalamus. It is well established in humans and animals that the melanocortin system controls energy balance, and the most common genetic cause of obesity in humans is congenital lack of MC4 R. It has recently been shown that many compounds that influence energy balance modify the activity of melanocortin circuits. In particular, it has been shown that bupropion and zonisamide increase the electrophysiological activity of POMC neurons. It has also been shown that cannabinoid antagonists activate this same circuitry. We have identified some of the receptors that can regulate the activity of POMC neurons; in particular we have shown that 5-HT 2C and 5-HT 1 B receptors increase the activity of POMC neurons as does dopamine D2 R. The

-33-

-36-
clear role of D2, R and 5-HT 2CR in regulating the activity of POMC neurons shows that compounds like olanzapine, which is an antagonist at both these receptors, modify energy balance to induce an anabolic state, favoring weight gain.

Study design
In vivo pharmacology

[0191] Rats receive implants that secrete olanzapine (or vehicle in control groups). Some also receive co-treatment with zonisamide; others get co-treatment with zonisamide plus bupropion. Initially, a dose of 30mg/kg of zonisamide (bid) is used, but the dose in the experiment ranges from 20 mg/kg to 90 mg/kg (bid). Bupropion is used initially at a dose of 190 mg/kg/day, the dose in the experiment ranges from 50-190 mg/kg/day. Olanzapine is used as a solution in minipumps. The concentration of the solution ranges between 0.1 µM to 10 mM. In some experiments, the concentration is calculated to provide a dose of about 1.75 mg/kg/day. In certain experiments, the concentration is 10 µM.

[0192] Preliminary data on the effect of zonisamide combined with bupropion on electrophysiological activity of POMC neurons in brain slices from POMC-EGFP mice show the increase in rate of spontaneous action potentials in POMC neurons. This large increase stimulates significant secretion of α-MSH from POMC neurons, and consequently activates MC4R— to inhibit food intake and decrease body weight gain.

Procedures
In vivo pharmacology

[0193] Female Sprague-Dawley rats weighing about 300 grams at the start of the experiment are used. Under isoflurane anesthesia, Alzet osmotic minipumps (2ml/2) are implanted subcutaneously, between the shoulder blades. The rats are returned to their home cages after recovery. The minipumps deliver 5 µL per hour for 14 days. Olanzapine is dissolved in dH2O + 10% dilute lactic acid. A pH of about 3.5 enables the olanzapine to dissolve completely and produce a golden solution. This pH level has no effect on the
animals in either the drug groups or the vehicle group. The animals are housed individually and are supplied with standard laboratory chow. Food consumed and animal weights are recorded every 3 days, to minimize disruption of the animals.

[0194] It has been shown in mice that zonisamide and zonisamide plus bupropion have pronounced effects on food intake over 24 hrs after intra-peritoneal injection. Similar mini-pump based methods are developed to test the effects of zonisamide and zonisamide plus bupropion on weight gain over 14 days using the following groups:

[0195] 7 groups of 6 rats (6 doses of zonisamide, + saline)
[0196] 7 groups of 6 rats (6 doses of bupropion, + saline)

[0197] The doses of zonisamide and bupropion that cause weight loss in this rat model are determined in smaller preliminary studies. The co-treatment experiments (olanzapine plus zonisamide plus bupropion) are then performed. Total animals tested are: 60+42+42 = 144 rats. The experiments are run three times to confirm the results.

Electrophysiology

[0198] The electrophysiological activity of Proopiomelanocortin (POMC) neurons in brain slices from POMC-EGFP mice are recorded. The POMC neurons in these mice are identified by the expression of green fluorescent protein (EGFP) in these, and only these, cells. The frequency of action potentials in these neurons are recorded using standard electrophysiological techniques. In particular, loose cell attached patch configuration is used to determine action potential frequency, whilst minimally disturbing the cells.

[0199] It has been shown that zonisamide and zonisamide plus bupropion increase the activity of POMC neurons. The basal activity is recorded, and then olanzapine is added to the tissue bath to determine the effect of olanzapine on the activity of POMC neurons. Pharmacological data show that olanzapine decreases the activity of POMC neurons. Then the increase in neuronal activity is tested again by treating the brain slices with zonisamide or zonisamide plus bupropion.

Example 12: Case study of combination of zonisamide, lamotrigine, and clonazepam

[0200] A 49 year-old woman having biopolar disorder, Type I, had been treated for just over year by her psychiatrist using clonazepam 1mg QHS, fluoxetine 20 mg qd, and lamotrigine 300 mg qD. One particular complaint was that she had "constant thoughts of..."
eating". Her psychiatrist started her on zonisamide 100 mg qD. She reported that the zonisamide significantly reduced her craving for food and prevented weight gain. The dose was continued and despite multiple stressors at home, she continued to do well on the treatment regimen.

Example 13: Case study of combination of zonisamide, paroxetine, and risperidone

[0201] A 45 year old female patient with social phobia and schizoaffective disorder was treated with paroxetine augmented with risperidone. She had marked increase in appetite and gained 40 pounds. A trial of bupropion alone did not cause significant weight loss. She was therefore started on zonisamide 100 mg, increased to 200mg. In 3 weeks she lost 12 pounds. The dose was then increased to 300 mg and then to 600 mg. In 5 months her weight returned to baseline. The psychiatric symptoms also improved.

Example 14: Case study of combination of zonisamide, olanzapine, valproate, and bupropion

[0202] A 30 year-old female patient with a diagnosis of bipolar disorder gained 56 lbs while receiving olanzapine and valproate over 5 years. Despite significant weight gain, her mental illness was effectively controlled, these medications were continued. She was clinically obese with a BMI of 33.8 kg/m². In an effort to assist in weight reduction, bupropion was added at 150 mg/day while olanzapine and valproate were continued. When bupropion dose was raised to 300 mg/day, the patient reported feeling hyperactive, hence, the dose was reduced back to 150 mg/day. After 6 months, the patient lost 23.6 lbs. However, while continuing to receive bupropion, the patient regained 10.6 lbs over the next 10 months. At this point, zonisamide was added to her medication regimen at 100 mg/day and the dose was increased to 200 mg/day after two weeks. The patient lost 15 lbs over the next 4 months and reported no adverse effects. She remained free of bipolar disorder symptoms.

[0203] The case illustrates two advantages of the combination therapy of bupropion and zonisamide. 1) Although bupropion helped in decreasing weight gain resulting from olanzapine and valproate, the patient could not take a higher dose (300-400 mg/day) of bupropion because of precipitation of hypomanic symptoms. The risk of induction of manic or hypomanic symptoms with use of antidepressant medications in susceptible patients is well documented. 2) Zonisamide helped in further offsetting weight gain associated with olanzapine and valproate after the patient lost weight initially with bupropion and regained some of weight lost.
The claims defining the invention are as follows:

1. A pharmaceutical composition for the reduction of weight gain associated with the use of a psychotherapeutic agent, said pharmaceutical composition comprising: a first compound, wherein said first compound is an atypical antipsychotic selected from the group consisting of olanzapine, clozapine, risperidone, quetiapine, aripiprazole, ziprasidone, and pharmaceutically acceptable salts thereof; a second compound, wherein said second compound is zonisamide or a pharmaceutically acceptable salt thereof; and a physiologically acceptable carrier diluent, or excipient, or a combination thereof, wherein said pharmaceutical composition is in a single oral dosage form.

2. The pharmaceutical composition of claim 1, wherein said first compound is olanzapine or a pharmaceutically acceptable salt thereof.

3. The pharmaceutical composition of claim 1, wherein said first compound is clozapine or a pharmaceutically acceptable salt thereof.

4. The pharmaceutical composition of claim 1, wherein said first compound is risperidone or a pharmaceutically acceptable salt thereof.

5. The pharmaceutical composition of claim 1, wherein said first compound is quetiapine or a pharmaceutically acceptable salt thereof.

6. The pharmaceutical composition of claim 1, wherein said first compound is aripiprazole or a pharmaceutically acceptable salt thereof.

7. The pharmaceutical composition of claim 1, wherein said first compound is ziprasidone or a pharmaceutically acceptable salt thereof.

8. A method of reducing weight gain associated with the use of a psychotherapeutic agent, comprising identifying an individual in need thereof and administering to said individual the composition of claim 1.

9. The method of claim 8, wherein said antipsychotic is olanzapine or a pharmaceutically acceptable salt thereof.
10. The method of claim 8, wherein said antipsychotic is clozapine or a pharmaceutically acceptable salt thereof.

11. The method of claim 8, wherein said antipsychotic is risperidone or a pharmaceutically acceptable salt thereof.

12. The method of claim 8, wherein said antipsychotic is quetiapine or a pharmaceutically acceptable salt thereof.

13. The method of claim 8, wherein said antipsychotic is aripiprazole or a pharmaceutically acceptable salt thereof.

14. The method of claim 8, wherein said antipsychotic is ziprasidone or a pharmaceutically acceptable salt thereof.

15. The pharmaceutical composition of claim 1, wherein said single oral dosage form is a tablet, pill, or capsule.

16. The pharmaceutical composition of claim 1, wherein said single oral dosage form comprises from about 25 mg to about 600 mg of zonisamide or a pharmaceutically acceptable salt thereof.

17. The pharmaceutical composition of claim 2, wherein said single oral dosage form comprises from about 25 mg to about 600 mg of zonisamide or a pharmaceutically acceptable salt thereof.

18. The pharmaceutical composition of claim 2, wherein said single oral dosage form comprises from about 1 mg to about 5000 mg of said olanzapine or pharmaceutically acceptable salt thereof.

19. The pharmaceutical composition of claim 2, wherein said single oral dosage form comprises 5 mg or 10 mg of said olanzapine or pharmaceutically acceptable salt thereof.

20. The pharmaceutical composition of claim 17, wherein said dosage form comprises 5 mg or 10 mg of said olanzapine or pharmaceutically acceptable salt thereof.

21. The pharmaceutical composition of claim 1, wherein said zonisamide or pharmaceutically acceptable salt thereof is a sustained release formulation.
22. The pharmaceutical composition of claim 2, wherein said zonisamide or pharmaceutically acceptable salt thereof is a sustained release formulation.

23. The pharmaceutical composition of claim 17 wherein said zonisamide or pharmaceutically acceptable salt thereof is a sustained release formulation.

24. The pharmaceutical composition of claim 18, wherein said zonisamide or pharmaceutically acceptable salt thereof is a sustained release formulation.

25. The pharmaceutical composition of claim 19, wherein said zonisamide or pharmaceutically acceptable salt thereof is a sustained release formulation.

26. The pharmaceutical composition of claim 20, wherein said zonisamide or pharmaceutically acceptable salt thereof is a sustained release formulation.

Dated: 1 October 2008
