BICYCLIC PYRIDINE AND PYRIMIDINE DERIVATIVES AS NEUROPEPTIDE Y RECEPTOR ANTAGONISTS

Background of the Invention

Neuropeptide Y ("NPY") is a 36 amino acid peptide related to and a member of the "PP" peptide family which includes peptide YY ("PYY") and pancreatic peptide ("PP") (See, Tatemoto, et al. Nature, 296, 659 (1982); Tatemoto, Proc. Natl. Acad. Sci USA, 79, 5485 (1982)). NPY is named for the presence of an N-terminal tyrosine and a C-terminal tyrosine amide and is the most abundant peptide neurotransmitter in the brain and central nervous system. NPY is found also in various parts of the peripheral nervous system. This peptide mediates several important biological activities through various receptors and receptor subtypes as discussed below.

In the brain, high NPY levels are found in the cerebral cortex, hippocampus, thalamus, hypothalamus and brainstem. Dense NPY staining occurs in the hypothalamic, brainstem and some limbic regions suggesting that NPY plays a role in somatic, sensory or cognitive brain function. Studies have suggested, also that NPY plays a role in the regulation of food intake, particularly in eating disorders including, for example, obesity, anorexia and bulimia, and memory retention and other cognitive functions, as well as anxiolysis and depression.
Additionally, NPY is found in both peripheral nerves and in the circulation. NPY appears to be a co-transmitter with norepinephrine, playing a role in vasoconstriction and hypertension, cardiac contractility, analgesia and hyperalgesia, as well as control of secretory activity in the intestine.

As noted, NPY and NPY analogs, mediate the noted biological functions through a family of closely related receptor and receptor subtypes. Presently, five receptor subtypes have been identified and are designated Y1 through Y5. Each receptor subtype generally is associated with different biological activities.

For example, the Y1 receptor is believed to be responsible for mediating many of the central and peripheral activities of NPY, including the anxiolytic and sedative effects, as well as the observed vasoconstrictive activities.

The Y2 receptor is predominant in the brain, particularly in the hippocampus. The Y2 receptor mediated effects are associated with inhibition of adenylate cyclase and inhibition of transmitter release. The Y2 receptor effects include vasoconstriction in some blood vessels, antisecretory effects in the intestine, enhanced memory retention, and inhibition of lipolysis.

The Y3 receptor effects are associated with inhibition of adenylate cyclase and elevation of intracellular calcium ion concentrations. Biological effects observed for Y3 include hypotension and bradycardia, inhibition of cardiac contractile force, inhibition of glutamate responsiveness and baroreceptor reflex, inhibition of catecholamine release and release of aldosterone.

The Y4 receptor (also referred to as "PPL" receptor) may be involved in pancreatic exocrine
secretion and hormonal control and may be important in diabetes or conditions associated with diabetes.

The most recently identified receptor is Y5 (sometimes referred to as "Y1-like" or "Feeding" receptor) (See, Gerald et al., Nature, 382, 168 (1996) and Hu et al., J. Biol. Chem., 271, 26315 (1996)). This receptor is associated with food intake and may mediate eating disorders such as obesity, bulimia and anorexia. Recently, Y5 has been implicated in the mediation of epileptic states and thus, NPY may be an endogenous anticonvulsant agent (See, e.g. Woldbye et al. Nat. Med., 3, 761 (1997)).

Because of the biological importance of NPY and the receptors with which it interacts, researchers have sought mediators, particularly antagonists, as novel therapeutic agents. A variety of peptide derivatives and analogs have been prepared in which amino acid modifications, substitutions, and deletions have been made relative to NPY. See, e.g., Hipskind, supra.

Although it would be preferable to have an easily synthesized, physically and metabolically stable and perhaps orally active NPY modulating compound, only a few non-peptide antagonists have been prepared. For example, a few non-peptidyl antagonists include the following:
Benextramine

Additionally, compounds of the following general structure, described in PCT publication, WO 97/34873 (published Sept. 25, 1997), are noted to be useful in the treatment of hyperphagia, obesity or diabetes:
Further, the following compound and related compounds are noted to be useful in NPY5 associated disorders and are disclosed in PCT publications, WO 97/20823, WO 97/20820, WO 97/20821, and WO 97/20822:

and WO 98/35944 and WO 98/35957 disclose substituted alkylamide NPY5 receptor antagonists.

Other published compounds include the following general formulae:

(See, respectively, PCT publication, WO 96/35689, published Nov. 14, 1996 - CRF1 receptor agonist or antagonist compounds useful for treating and diagnosis of stress related disorders; and PCT publication, WO 97/29110, published Aug. 14, 1997 - CRF receptor antagonist compounds useful for treating disorders relating to hypersecretion of CRF); and,
Obesity, defined as an excess of body fat relative to lean body mass, is associated with important psychological and medical morbidities, the latter including hypertension, elevated blood lipids, and Type II or non-insulin dependent diabetes mellitus ("NIDDM"). There are over 6 million individuals with NIDDM in the United States, including approximately 20% of the population 65 years or older. See, Harris et al., Int. J. Obes., 11, 275 (1987). Approximately 45% of males and 70% of females with NIDDM are obese, and their diabetes is substantially improved or eliminated by weight reduction. See, Harris, Diabetes Care, 14(3), 639 (1991).

The assimilation, storage and utilization of nutrient energy is a complex system central to survival of a warm-blooded animal. Among land-dwelling mammals, storage in adipose tissue of large quantities of metabolic fuel as triglycerides is crucial for surviving through periods of food deprivation. The need to maintain a fixed level of energy stores without continual alteration in the size and shape of an organism requires the achievement of a balance between energy intake and expenditure.

Models of obesity which use animals with mutations in the ob and db gene indicate that the animals have an altered metabolism of carbohydrates resembling Type II diabetes in humans. These animals show effects which resemble other aspects of obesity. In particular, mice with these mutations eat more food and expend less energy than lean control animals. The phenotype is
similar to that observed in animals with lesions of the ventromedial hypothalamus which indicates that the noted mutations may interfere with the ability to properly integrate or respond to nutritional information within the central nervous system. See, for example, Coleman, Diabetologia, 2, 294 (1973).

These studies and others related to NPY and NPY receptors show that there is an interaction of a variety of mechanisms involved in the development and maintenance of obesity, overeating and apparently related disease states such as diabetes, or even other NPY mediated disease states such as anxiety and depression. These may include a variety of genetic factors including modifications in the ob, db and NPY genes or receptors, or gene products which affect or modulate these receptors or gene products, including control mechanisms of these receptors or gene products, or control mechanisms of other receptors or targets either upstream or downstream in the signaling pathway from the noted genes, receptors or other target molecules.

Given the variety of clinical states associated with eating disorders, including hyperphagia, obesity, diabetes, and other disease states related to the various mechanisms involved including, for example, NPY pathways, a need exists for additional compounds capable of modulating such activities. In particular, there is a need to provide new approaches for the treatment or prophylaxis of obesity, overeating and diabetes and other diseases which are mediated by the same or related pathways associated with these diseases.

WO 98/06703 discloses that compounds of the general formula
wherein A, W, X, Y, Z, R₁, R₂, R₄ and R₅ are as defined therein, are monocyte chemoattractant protein 1 (MCP-1) receptor antagonists and are capable of inhibiting the binding of MCP-1 to its receptor. MCP-1, a chemokine (chemoattractant cytokine), appears to be involved in inflammation by acting on monocytes, activated memory T cells and on basophils. MCP-1 is a potent secretagogue of inflammatory mediators for monocytes and basophils and appears to have chemotactic activity for human monocytes and/or T cells. MCP-1 may also play a role in allergic hypersensitivity disease. Further, MCP-1 selectively activates the B1 integrin family of leukocyte adhesion molecule and may play a role in leukocyte interactions with the extracellular matrix. Thus, MCP-1 may not only trigger the initial arrest and adhesion of monocytes and T cells, but may also act to guide their migration in extravascular space.

WO 98/08847

wherein R₁, R₂, A, B, D, E, G, J and K are as defined therein, are corticotropin releasing factor (CRF) antagonists, corticotropin releasing factor hormone (CRH) binding protein inhibitors and are also useful in the treatment of inflammatory disorders. The CRF antagonists were reported to be effective in the treatment of stress-related illnesses, mood disorders
such as depression, major depressive disorder, single episode depression, recurrent depression, child abuse induced depression, postpartum depression, dysthemia, bipolar disorders and cyclothymia; chronic fatigue syndrome; eating disorders such as anorexia and bulimia nervosa; generalized anxiety disorder; panic disorder; phobias; obsessive-compulsive disorder, post-traumatic stress disorder, pain perception such as fibromyalgia; headache; gastrointestinal diseases; hemorrhagic stress; ulcers; stress-induced psychotic episodes; fever; diarrhea; post-operative ileus, colonic hypersensitivity; irritable bowel syndrome; Crohn's disease; spastic colon; inflammatory disorders such as rheumatoid arthritis and osteoarthritis; pain; asthma; psoriasis; allergies; osteoporosis; premature birth; hypertension, congestive heart failure; sleep disorders; neurodegenerative diseases such as Alzheimer's disease, senile dementia of the Alzheimer's type, multiinfarct dementia, Parkinson's disease, and Huntington's disease; head trauma; ischemic neuronal damage; excitotoxic neuronal damage; epilepsy; stroke; spinal cord trauma; psychosocial dwarfism; euthyroid sick syndrome; syndrome of inappropriate antidiuretic hormone; obesity; chemical dependencies and addictions; drug and alcohol withdrawal symptoms; cancer; infertility; muscular spasms; urinary incontinence; hypoglycemia and immune dysfunctions including stress induced immune dysfunctions, immune suppression and human immunodeficiency virus infections; and stress-induced infections in humans and animals. CRH binding protein inhibitors were reported to be effective in the treatment of Alzheimer's disease and obesity.

WO 98/08846
discloses that compounds of the general formula

wherein R₅, R₆, A, B, D, E, G and K are as defined therein, are CRF antagonists, CRH binding protein inhibitors and are also useful in the treatment of inflammatory disorders.

WO 98/07726
discloses that compounds of the general formula

wherein R, R₁, R₂, R₃, n and q are as defined therein, are protein tyrosine kinase inhibitors and/or inhibitors of protein serine/threonine kinases. The compounds were reported to inhibit the tyrosine kinase activity of the receptor for the epidermal growth
factor (EGF) and of c-erbB2 kinase. These receptor-specific enzyme activities play a key role in signal transmission in a large number of mammalian cells, including human cells, especially epithelial cells, cells of the immune system and cells of the central and peripheral nervous system. In various cell types, EGF-induced activation of receptor-associated protein tyrosine kinase (EGF-R-PTK) is a prerequisite for cell division and thus for the proliferation of the cell population. Inhibition of protein kinases, such as EGF-receptor-specific tyrosine kinase, inhibits the proliferation of the cells. The compounds were also reported to inhibit other protein tyrosine kinases that are involved in signal transmission mediated by trophic factors, for example abl kinase (such as v-abl kinase), kinases from the family of the src kinases (such as c-src kinase), lck, fyn, other kinases of the EGF family (such as c-erbB2 kinase (HER-2), c-erbB3 kinase, c-erbB4 kinase), members of the family of the PDGF receptor protein tyrosine kinases (such as PDGF receptor kinase, CSF-1 receptor kinase, Kit receptor kinase, VEGF receptor kinase and FGF receptor kinase), the receptor kinase of the insulin-like growth factor (IGF-1 kinase), and serine/threonine kinases (such as protein kinase C or cdc kinases), all of which play a part in growth regulation and transformation in mammalian cells, including human cells.

As one skilled in the art will appreciate such heterocyclic moieties may exist in several isomeric forms, all of which are to be encompassed by the present invention. For example, a 1,3,5-triazine moiety is isomeric to a 1,2,4-triazine group. Such positional isomers are to be considered within the scope of the present invention. Likewise, the heterocyclic or heteroaryl groups can be bonded to other moieties in the compounds of the invention. The point(s) of attachment to these other moieties is not to be construed as limiting on the scope of the invention. Thus, by way of example, a pyridyl moiety may be bound to other groups through the 2-, 3-, or 4-position of the pyridyl group. All such configurations are to be construed as within the scope of the present invention.

Examples of heterocyclic or heteroaryl moieties included in the scope of the present invention may include, but are not limited to, the following:
The term "halo" or "halogen" refers to a halogen atom which may include fluoro, chloro, bromo and iodo.

"Modulate" as used herein refers to the ability of a compound of this invention to interact with a receptor, target gene or other gene product to (a) up-regulate the activity of that receptor, target gene or other gene product or biological effect (for example, as an agonist) or (b) down-regulating the receptor, target gene or other gene product or other biological effect, particularly by acting as an antagonist for the receptor, target gene or other gene product.

Additionally, encompassed by "modulate" is the ability of a compound of the invention to effect a desired biological response, even if that response occurs upstream or downstream one or more steps in a signaling pathway from the receptor, target gene or other gene product in question. Thus, by way of example, the compounds of the invention may provide the desired effect by interacting with an NPY receptor, particularly an NPY5 receptor, to act as an agonist or antagonist to that receptor or at some point, either upstream or downstream, in the signaling pathway for the NPY receptor to effect the desired therapeutic or prophylactic response.

"Pharmaceutically acceptable salt", as used herein, refers to an organic or inorganic salt which is useful in the treatment of a warm-blooded animal. Such
salts can be acid or basic addition salts, depending on the nature of the compound of this invention. For examples of "pharmacologically acceptable salts," see Berge et al., J. Pharm. Sci. 66:1 (1977). As used herein, "warm blooded animal" includes a mammal, including a member of the human, equine, porcine, bovine, murine, canine or feline species.

In the case of an acidic moiety in a compound of this invention, a salt may be formed by treatment of a compound of this invention with a basic compound, particularly an inorganic base. Preferred inorganic salts are those formed with alkali and alkaline earth metals such as lithium, sodium, potassium, barium and calcium. Preferred organic base salts include, for example, ammonium, dibenzylammonium, benzylammonium, 2-hydroxyethylammonium, bis(2-hydroxyethyl)ammonium, phenylethylbenzylamine, dibenzyl-ethylenediamine, and the like salts. Other salts of acidic moieties may include, for example, those salts formed with procaine, quinine and N-methylglucosamine, plus salts formed with basic amino acids such as glycine, ornithine, histidine, phenylglycine, lysine and arginine. An especially preferred salt is a sodium or potassium salt of a compound of this invention.

With respect to basic moieties, a salt is formed by the treatment of a compound of this invention with an acidic compound, particularly an inorganic acid. Preferred inorganic salts of this type may include, for example, the hydrochloric, hydrobromic, hydroiodic, sulfuric, phosphoric or the like salts. Preferred organic salts of this type, may include, for example, salts formed with formic, acetic, succinic, citric, lactic, maleic, fumaric, palmitic, cholic, pamoic, mucic, d-glutamic, d-camphoric, glutaric, glycolic, phthalic, tartaric, lauric, stearic, salicylic, methanesulfonic, benzenesulfonic, para-toluenesulfonic,
sorbic, puric, benzoic, cinnamic and the like organic acids. An especially preferred salt of this type is a hydrochloride or sulfate salt of a compound of this invention.

Also encompassed in the scope of the present invention are pharmaceutically acceptable esters of a carboxylic acid or hydroxyl containing group, including a metabolically labile ester or a prodrug form of a compound of this invention. A metabolically labile ester is one which may produce, for example, an increase in blood levels and prolong the efficacy of the corresponding non-esterified form of the compound. A prodrug form is one which is not in an active form of the molecule as administered but which becomes therapeutically active after some in vivo activity or biotransformation, such as metabolism, for example, enzymatic or hydrolytic cleavage. For a general discussion of prodrugs involving esters see Svensson and Tunek Drug Metabolism Reviews 165 (1988) and Bundgaard Design of Prodrugs, Elsevier (1985). Amines have been masked as arylcarbonyloxyethyl substituted derivatives which are cleaved by esterases in vivo releasing the free drug and formaldehyde (Bundgaard J. Med. Chem. 2503 (1989)). Also, drugs containing an acidic NH group, such as imidazole, imide, indole and the like, have been masked with N-aclyloxyethyl groups (Bundgaard Design of Prodrugs, Elsevier (1985)). Hydroxy groups have been masked as esters and ethers. EP 039,051 (Sloan and Little, 4/11/81) discloses Mannich-base hydroxamic acid prodrugs, their preparation and use. Esters of a compound of this invention, may include, for example, the methyl, ethyl, propyl, and butyl esters, as well as other suitable esters formed between an acidic moiety and a hydroxyl containing moiety. Metabolically labile esters, may include, for example, methoxymethyl, ethoxymethyl, iso-
propoxymethyl, α-methoxyethyl, groups such as α-
((C₁-C₅)alkyloxy)ethyl; for example, methoxyethyl,
ethoxyethyl, propoxyethyl, iso-propanoxyethyl, etc.; 2-
oxo-1,3-dioxolen-4-ylmethyl groups, such as 5-methyl-2-
oxo-1,3-dioxolen-4-ylmethyl, etc.; C₁-C₅ alkylthiomethyl
groups, for example, methylthiomethyl, ethylthiomethyl,
isopropylthiomethyl, etc.; acyloxyethyl groups, for
example, pivaloyloxyethyl, α-acetoxyethyl, etc.;
ethoxycarbonyl-1-methyl; or α-acyloxy-α-substituted
methyl groups, for example α-acetoxyethyl.

Additionally, the compounds of the invention may
have one or more asymmetric carbon atoms and,
therefore, may exist in stereoisomeric forms. All
stereoisomers are intended to be included within the
scope of the present invention. As used,
"stereoisomer" or "stereoisomeric" refers to a compound
which has the same molecular weight, chemical
composition, and constitution as another, but with the
atoms grouped such that their orientation in three-
dimensional space is different. Such stereoisomers may
exist as enantiomeric mixtures, diastereomers or may be
resolved into individual stereoisomeric components
(e.g. specific enantiomers) by methods familiar to one
skilled in the art.

Likewise, the compounds of this invention may
exist as isomers, that is compounds of the same
molecular formula but in which the atoms, relative to
one another, are arranged differently. In particular,
the alkenylene substituents of the compounds of this
invention, are normally and preferably arranged and
inserted into the molecules as indicated in the
definitions for each of these groups, being read from
left to right. However, in certain cases, one skilled
in the art will appreciate that it is possible to
prepare compounds of this invention in which these
substituents are reversed in orientation relative to the other atoms in the molecule. That is, the substituent to be inserted may be the same as that noted above except that it is inserted into the molecule in the reverse orientation. One skilled in the art will appreciate that these isomeric forms of the compounds of this invention are to be construed as encompassed within the scope of the present invention.

Further, the compounds of the invention may exist as crystalline solids which can be crystallized from common solvents such as ethanol, N,N-dimethylformamide, water, or the like. Thus, crystalline forms of the compounds of the invention may exist as solvates and/or hydrates of the parent compounds or their pharmaceutically acceptable salts. All of such forms likewise are to be construed as falling within the scope of the invention.

While it may be possible to administer a compound of the invention alone, in the methods described, the compound administered normally will be present as an active ingredient in a pharmaceutical formulation. Thus, in one another embodiment of the invention, there is provided a formulation comprising a compound of this invention in combination with a pharmaceutically acceptable carrier, diluent or excipient therefor.

The composition used in the noted therapeutic methods can be in a variety of forms. These include, for example, solid, semi-solid and liquid dosage forms, such as tablets, pills, powders, liquid solutions or suspensions, liposomes, injectable and infusible solutions. The preferred form depends on the intended mode of administration and therapeutic application. Considerations for preparing appropriate formulations will be familiar to one skilled in the art and are described, for example, in Goodman and Gilman's: "The Pharmacological Basis of Therapeutics", 8th Ed.,
Pergamon Press, Gilman et al. eds. (1990); and "Remington's Pharmaceutical Sciences", 18th Ed., Mack Publishing Co., A. Gennaro, ed. (1990). Methods for administration are discussed therein, e.g. for oral, topical, intravenous, intraperitoneal, or intramuscular administration. pharmaceutically acceptable carriers, diluents, and excipients, likewise, are discussed therein. Typical carriers, diluents, and excipients may include water (for example, water for injection), buffers, lactose, starch, sucrose, and the like.

As noted, a compound of the invention can be administered orally, topically or parenterally (e.g. intravenously, intraperitoneally, intramuscularly, subcutaneously, etc.), or inhaled as a dry powder, aerosol, or mist, for pulmonary delivery. Such forms of the compounds of the invention may be administered by conventional means for creating aerosols or administering dry powder medications using devices such as for example, metered dose inhalers, nasal sprayers, dry powder inhaler, jet nebulizers, or ultrasonic nebulizers. Such devices optionally may be include a mouthpiece fitted around an orifice. In certain circumstances, it may be desirable to administer the desired compound of the invention by continuous infusion, such as through a continuous infusion pump, or using a transdermal delivery device, such as a patch.

The compounds of the invention may also be administered as an aerosol. The term "aerosol" includes any gas-borne suspended phase of a compound of the invention which is capable of being inhaled into the bronchioles or nasal passages. Specifically, aerosol includes a gas-borne suspension of droplets of the desired compound, as may be produced in a metered dose inhaler or nebulizer, or in a mist sprayer. Aerosol also includes a dry powder composition of a
compound of the instant invention suspended in air or other carrier gas, which may be delivered by insufflation from an inhaler device, for example.

For solutions used in making aerosols of the invention, the preferred range of concentration of the compounds of the invention is 0.1-100 milligrams (mg)/milliliter (mL), more preferably 0.1-30 mg/mL, and most preferably 1-10 mg/mL. Usually the solutions are buffered with a physiologically compatible buffer such as phosphate or bicarbonate. The usual pH range is from about 5 to about 9, preferably from about 6.5 to about 7.8, and more preferably from about 7.0 to about 7.6. Typically, sodium chloride is added to adjust the osmolarity to the physiological range, preferably within 10% of isotonic. Formulation of such solutions for creating aerosol inhalants is discussed, for example, in Remington's, supra; See also, Ganderton and Johens, "Drug Delivery to the Respiratory Tract, Ellis Horwood (1987); Gonda, "Critical Review in Therapeutic Drug Carrier Systems" 6 273-313 (1990); and Raeburn et al. J. Pharmacol. Toxicol. Methods. 27 143-159 (1992).

Solutions of a compound of the invention may be converted into aerosols by any of the known means routinely used for making aerosol inhalant pharmaceuticals. In general, such methods comprise pressurizing or providing a means of pressurizing a container of the solution, usually with an inert carrier gas, and passing the pressurized gas through a small orifice, thereby pulling droplets of the solution into the mouth and trachea of the animal to which the drug is to be administered. Typically, a mouthpiece is fitted to the outlet of the orifice to facilitate delivery into the mouth and trachea.

In one embodiment, devices of the present invention comprise solutions of the compounds of the
invention connected to or contained within any of the conventional means for creating aerosols in asthma medication, such as metered dose inhalers, jet nebulizers, or ultrasonic nebulizers. Optionally such devices may include a mouthpiece fitted around the orifice.

Further, there are provided a device which may comprise a solution of a compound of the instant invention in a nasal sprayer.

A dry powder comprising a compound of the invention, optionally with an excipient is another embodiment. This may be administered by a drug powder inhaler containing the described powder.

Powders may be formed with the aid of any suitable powder bases, for example, talc, lactose, starch and the like. Drops may be formulated with an aqueous base or non-aqueous base also comprising one or more dispersing agents, suspending agents solubilizing agents, and the like.

Any of the formulations of the invention may also include one or more preservatives or bacteriostatic agents, for example, methyl hydroxybenzoate, ethyl hydroxybenzoate, propyl hydroxybenzoate, chlorocresol, benzalkonium chlorides, and the like. Additionally, the formulations may contain other active ingredients.

The pharmaceutical formulations of the invention may be administered by parenteral or oral administration for prophylactic and/or therapeutic treatment. The pharmaceutical compositions can be administered in a variety of unit dosage forms depending on the method of administration. For example, unit dosage forms suitable for oral administration may include, powders, tablets, pills, capsules and dragees.

The pharmaceutical formulations can be administered intravenously. Therefore, the invention
further provides formulations for intravenous administration which comprise a compound of the invention dissolved or suspended in a pharmaceutically acceptable carrier or diluent therefor. A variety of aqueous carriers can be used, for example, water, buffered water or other buffer solutions, saline, and the like. The resulting aqueous solutions can be packaged for use as is, or lyophilized, the lyophilized preparation being combined with a sterile aqueous solution prior to administration. The sterile aqueous solution for the lyophilized product can be packaged as a kit for use with the lyophilized formulation. The compositions can contain pharmaceutically acceptable substances to aid in administration and more closely mimic physiological conditions. Such substances, can include, for example, pH adjusting substances such as acids, bases or buffering agents, tonicity adjusting agents, wetting agents and the like. Such substances may include but are not limited to, for example, sodium hydroxide, hydrochloric acid, sulfuric acid, sodium acetate, sodium lactate, sodium chloride, potassium chloride, calcium chloride, sorbitan monolaurate, triethanolamine oleate, and the like or any other means familiar to one skilled in the art for maintaining pH at a desired level.

For solid formulations, carriers, diluents, and excipients known to one skilled in the art may be used. Such carriers, diluents and excipients may include, for example, mannitol, lactose, starch magnesium stearate, sodium saccharin, talcum, cellulose, glucose, sucrose, or other solid polyol sugar, magnesium carbonate, and the like. For oral administration, a pharmaceutically acceptable formulation is prepared by admixing any of the usual carrier, diluents, and excipients, such as those noted, with from about 0.1 to about 95% of a compound of the invention.
The preferred dosage for use in the methods of the invention, however, is in the range of about 0.01 mg/kg to about 100 mg/kg of body weight, preferably from about .1 mg/kg to about 50 mg/kg, up to 4 times per day. Whatever the dosage form, one skilled in the art will recognize that the dosage administered will be adjusted to factors such as the age, weight, and condition of the patient involved. The skilled practitioner will be familiar with how to adjust the dosage to accommodate these and other factors.

To better understand the synthesis of the compounds of this invention, Fig. 1 outlines a general reaction scheme for the synthesis of pyrrolo[3,2-d]pyrimidines of the invention. Fig. 2 also outlines a general reaction scheme for the synthesis of pyrrolo[3,2-d]pyridines and pyrrolo[3,2-d] pyrimidines while Fig. 3 provides a general process for the synthesis of thiopheno-, furano-, and pyrrolo-[3,2-d]-pyrimidines and -pyridines of the invention. Further, Fig. 4 provides a general process for the synthesis of 5-hydrocyclopenta-[2,1-d]pyrimidines of the invention.

The reactions described in the figures may be carried out in any number of solvents in which the reactants may be mutually soluble, including, for example, tetrahydrofuran, benzene, toluene, chloroform, dichloromethane, N,N-dimethylformamide, ethyl ether, dioxane, water, acetonitrile, or the like. Generally the reaction is carried out at a temperature of between -80°C and 150°C, preferably, however, at room temperature. In certain cases, as noted in the examples provided herein, however, the temperature of the reaction may reach as high as or exceed about 360°C.

The product and intermediates may be isolated or purified using one or more standard purification techniques, including, for example, one or more of
simple solvent evaporation, recrystallization, distillation, sublimation, filtration, chromatography, including thin-layer chromatography, HPLC (e.g. reverse phase HPLC using, for example, dilute trifluoroacetic acid in water, acetonitrile, or methanol mixtures as eluent), column chromatography, flash chromatography, radial chromatography, trituration, and the like.

In the preparation of the compounds of the invention, one skilled in the art will understand that one may need to protect or block various reactive functionalities on the starting compounds or intermediates while a desired reaction is carried out on other portions of the molecule. After the desired reactions are complete, or at any desired time, normally such protecting groups will be removed by, for example, hydrolytic or hydrogenolytic means. Such protection and deprotection steps are conventional in organic chemistry. One skilled in the art is referred to "Protective Groups in Organic Chemistry," McOmie, Ed., Plenum Press, New York, New York; and "Protective Groups in Organic Synthesis," Greene, Ed., John Wiley & Sons, New York, NY (1981) for the teaching of protective groups which may be useful in the preparation of compounds of the present invention.

Alternate means beyond those described above for preparing the compounds of the invention will be apparent to one skilled in the art and the noted general procedures are not to be construed as limiting the invention. To more fully understand the invention, including methods of preparing compounds of the invention, the following non-limiting examples are provided. The reader will appreciate that starting materials not otherwise described herein are either available commercially or can be prepared by methods generally known in the art.
Unless otherwise noted, all materials were obtained from commercial suppliers and used without further purification. Anhydrous solvents such as dimethylformamide (DMF), tetrahydrofuran (THF), dichloromethane (CH₂Cl₂), and toluene, dioxane were obtained from Aldrich Chemical Company in Sure/Seal bottles. All reactions involving air- or moisture-sensitive compounds were performed under a N₂ atmosphere. Flash chromatography was performed using ICN Biomedicals (SiliTech*32-63D 60A). Thin-layer chromatography (TLC) was performed with Analtech* or Whatman* silica gel TLC plates (250 μm). Preparatory TLC was performed with Whatman* silica gel TLC plates (2000 μm). ¹H NMR spectra were determined with superconducting FT NMR spectrometers operating at 400 and 500 MHz. Chemical shifts are expressed in ppm downfield from internal tetramethylsilane. Significant ¹H NMR data are reported in the following order: multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; quin, quintet), number of protons, and coupling constants in Hz. Elemental analyses were performed by Atlantic Microlab, Inc., Norcross, GA. Melting points were determined with a Buchi*535 capillary melting point apparatus and are uncorrected. Low resolution mass spectra (MS) were determined on a Perkin Elmer-SCIEX API 165* mass spectrometer using APCI or ES ionization modes (positive or negative). High resolution mass spectra (HRMS) were performed by Mass Consortium, San Diego, CA using FAB ionization.

(a) Ethyl 2-(hydroxyimino)-3-oxybutyrate.

A solution of ethyl acetoacetate (Aldrich Chemical Company) (37.5 g, 0.279 mol) in acetic acid (55 mL) was cooled in an ice-water bath. A solution of sodium nitrite (26.5 g, 0.384 mol) in distilled H₂O (60 mL) was added to the cooled reaction mixture over a 0.5 h period via a pressure-equalizing addition funnel. Upon this addition, the colorless reaction mixture turned a red-orange color. The cold bath was removed and the solution was allowed to stir at room temperature for 2 h. The red solution was transferred to a separatory funnel and extracted with Et₂O (3 x 100 mL). The organic extracts were placed in a 1-L beaker equipped with a magnetic stirring bar. Saturated aqueous NaHCO₃ was added and the solution was stirred vigorously. Additional portions of solid NaHCO₃, were added to neutralize the solution. The aqueous layer was separated and extracted with ether. The organic layers were combined, washed with water and saturated NaCl, and dried over MgSO₄. The solution was filtered and concentrated with a rotary evaporator to give 42.5 g (95%) of the title compound as a pale yellow oil. ¹H NMR (CDCl₃, 500 MHz): δ 1.36 (t, 3, J = 7.1), 2.42 (s, 3), 4.39 (q, 2, J = 7.1), 9.05 (m, 1). MS m/z : 160 (M+1). This material was used without further purification.
(b) Ethyl 3-oxo-2-(phenylcarbonylamino)butanoate.

To a 1-L, round-bottomed flask was added ethyl 2-(hydroxyimino)-3-oxybutyrate (25.0 g, 0.157 mol), $\text{H}_2\text{SO}_4$ (30% w/v) (230 mL) and crushed ice (250 g). This solution was cooled in an ice-salt-water bath and the internal temperature was monitored with an alcohol thermometer. Powdered zinc (100 mesh - Aldrich Chemical Company) (30.0 g, 0.459 mol, 2.9 equiv) was added to this cooled solution portionwise via a powder addition funnel. The temperature of the reaction was maintained between 0-10 °C. After the addition of the zinc was complete the reaction mixture was allowed to stir at 0 °C for 0.5 h. The solution was filtered through a fritted funnel into a clean 1-L round-bottomed flask. This clear, colorless solution was cooled in an ice-water bath and sodium acetate trihydrate (Aldrich Chemical Company) (162.5 g, 1.19 mol) was added with stirring. Benzoyl chloride (Aldrich Chemical Company) (18.3 mL, 22.1 g, 0.157 mol) was slowly added to the resulting cloudy solution via a syringe. After the addition was complete, the cold bath was removed and the solution was allowed to stir at room temperature for 24 h. The yellow reaction mixture was extracted with $\text{CH}_2\text{Cl}_2$ (3 x 100 mL). The organic layers were washed with saturated aqueous $\text{NaHCO}_3$, dried over $\text{MgSO}_4$, filtered, and concentrated on a rotary evaporator to give 30.3 g of a yellow oil. This material was purified by flash chromatography on silica gel with 4:1 hexanes: EtOAc as eluant to give 20.0 g (51%) of the title compound as a viscous pale-

(c) 2,6-Dimethyl-4-hydroxy-5-benzamidopyrimidine.

Absolute EtOH (150 mL) was added to an oven-dried round-bottomed flask, and small pieces of sodium (4.95 g, 0.215 mol) were added portionwise. A reflux condenser was attached to the flask and the solution was allowed to stir at room temperature until all of the sodium was consumed. Acetamidine hydrochloride (Aldrich Chemical Company) (9.95 g, 0.105 mol) was added in one portion and the resulting creamy white solution was allowed to stir at room temperature for 0.5 h. In a separate flask ethyl 3-oxo-2-(phenyl carbonylamino)butanoate (23.8 g, 0.956 mol) was dissolved in absolute EtOH (30 mL). The acetamidine solution was filtered through a plug of celite into the ketoester solution. As this solution was added, the reaction mixture turned from an orange to a dark brown color. The mixture was placed under a N$_2$ atmosphere and allowed to stir at room temperature overnight. As the reaction proceeded solids precipitated out of solution to give a thick brown-orange mixture. The reaction mixture was filtered through a fritted funnel and the solids were washed with EtOH. The solids were dissolved in distilled H$_2$O and HCl (conc.) was added to acidify the solution to a pH of 4-5 (pH paper). Upon acidification solids precipitated out of solution. The solution was cooled in an ice-water bath, the solids
were filtered, washed with cold water and dried in a vacuum oven to give 7.59 g (33%) of the title compound as a white powder. The EtOH filtrate was concentrated with a rotary evaporator to give 13 g of a sticky orange oil. This material was purified by flash chromatography on silica gel with 95:5 CH₂Cl₂:MeOH as eluant to give an additional 2.61 g (11%) of the title compound as fluffy pale-yellow flakes (total yield 10.2 g (44%)). (d) 2-Methyl-6-phenylpyrrolo[3,2-d]pyrimidin-4-ol.

**Method A:** To an oven-dried, 250-mL, round-bottomed flask was added absolute EtOH (45 mL). Small pieces of sodium metal (2.87 g, 0.125 mol) were added portionwise. After all of the sodium was consumed, 2, 6-dimethyl-4-hydroxy-5-benzamidopyrimidine (10.1 g, 41.7 mol) was added in one portion via a powder addition funnel. An additional portion of EtOH (20 mL) was added to rinse the last portion of the amide from the funnel. The reaction mixture was heated at reflux for 0.25 h until all of the solids dissolved to give an orange solution. The condenser was replaced with a short-path distillation head and the EtOH was distilled off under a \(N_2\) atmosphere. The resulting solids were scraped off the sides of the flask with a spatula and heated with a heating mantle at 360 °C for 20 min. The
residue was allowed to cool to room temperature, dissolved in distilled H₂O (35 mL), and HCl (conc.) was added portionwise to adjust the pH of the solution to 4-5 (pH paper). The resulting precipitate was filtered and dried in a vacuum oven to give 6.38 g of a tan solid. This material was dissolved in 3 N NaOH (~30 mL), and the resulting dark brown solution was filtered through a fritted funnel. Acetic acid was added to the filtrate with stirring. The resulting solids were filtered, washed with distilled H₂O, recrystallized from EtOH and dried in a vacuum oven to give 1.45 g (15%) of the title compound as a tan powder. Mp: >280 °C (lit mp = 322 (dec.). K. Tanaka et al., Chem. Pharm. Bull. 1964, 12, 1024-1030). ¹H NMR (DMSO-d₆; 400 MHz):

**Method B:** To an oven-dried, 100-mL, round-bottomed flask equipped with a glass-covered magnetic stir bar was added absolute EtOH (35 mL). Small pieces of sodium metal (Aldrich Chemical Company) (1.89 g, 0.082 mol) where added portionwise. After all of the sodium was consumed, 2,6-dimethyl-4-hydroxy-5-benzamido pyrimidine (5.0 g, 0.02 mol) was added in one portion via a powder addition funnel. An additional portion of EtOH (2 mL) was added to rinse the last portion of the amide from the funnel. A reflux condenser was attached to the flask and the mixture was heated at reflux for 0.5 h until all of solid dissolved to give a yellow solution. The reflux condenser was replaced with a short-path distillation head and the EtOH was distilled off under a N₂ atmosphere. The resulting yellow solids were heated with a sand bath at 340 °C for 15-20 min.
The residue was allowed to cool to room temperature and dissolved in distilled water (50 mL). The resulting brown solution, which contained black pieces of solids, was filtered through a Buchner funnel into a round-bottomed flask. An additional portion of water (50 mL) was added to rinse the reaction flask. The dark-brown solution (pH = 12) was transferred to a 250-mL beaker. HCl (conc.) was added dropwise to adjust the pH of the solution to 4-5 (pH paper). Precipitate formed instantly upon acidification. The suspension was stirred for 2 h, filtered, washed by cold water and dried in a vacuum oven at 40 °C overnight to give 3.20 g (69%) of the title compound as a fine tan powder (98 % pure by HPLC). ¹H NMR of this material was identical to that obtained in Method A. This material was used without further purification.

The resulting dark-red solution was placed under N₂ and heated at reflux for 3 h. The solution was concentrated with a rotary evaporator to give a dark red oil. This material was cooled in an ice-water bath and distilled H₂O was added. The solution was filtered through a fritted funnel, and the filtrate was concentrated with a rotary evaporator to give a wet

The organic layer was dried over MgSO₄, filtered and concentrated with a rotary evaporator to give 0.98 g of an orange oil. This material was purified by flash chromatography on silica gel with 4:1 hexanes:EtOAc followed by 1:1 hexanes:EtOAc as eluant to give 0.24 g (44%) of the title compound as a tan solid. ¹H NMR (CDCl₃; 400 MHz) : δ 2.76 (s, 3), 6.90 (s, 1), 7.43 (m, 3), 7.80 (dm, 2, J = 6.5), 10.17 (br s, 1). MS m/z : 243 (M'), 208 (base).

Method B: Phosphorus oxychloride (Aldrich Chemical Company) (30 mL, 0.322 mol) was added to a 100-mL, oven-dried, round-bottomed flask containing a magnetic stir bar and 2-methyl-6-phenylpyrrolo[3,2-d]pyrimidin-4-ol (2.8 g, 0.012 mol). Stirring was continued for 12 h at room temperature. Water (100 mL) was added, and the resulting precipitate was collected by filtration and washed with H₂O. Recrystallization from H₂O followed by drying in the vacuum oven provided 20 g (68 %) of the title compound as a white crystalline solid. \(^1\)H NMR (DMSO-\(d_6\); 400 MHz): \(\delta\) 3.9 (s, 3). \(^13\)C NMR (DMSO-\(d_6\); 100.6 MHz): \(\delta\) 17.94, 118.0, 155.7, 161.7. (b) 2-Methyl-4,6-dichloro-5-nitropyrimidine.

To a round-bottomed flask equipped with a Dean-Stark trap, reflux condensor, pressure-equalized addition funnel, magnetic stirrer, heating mantel and internal temperature probe was added 2-methyl-4,6-dihydroxy-5-nitropyrimidine (Example 76(a)) (2.0 g, 11 mmol) and toluene (16 mL). The Dean-Stark trap was filled with toluene (12 mL). For 3 h, the reaction mixture was heated at reflux during which time water collected in the Dean-Stark trap. Heat was removed from the reaction vessel, and after 20 min, diisopropylethylamine (Aldrich Chemical Company) (2.8 mL, 16 mmol) was poured into the reaction mixture through the reflux condensor. The reaction mixture was heated at reflux again, and POCl₃ (Aldrich Chemical Company) (7 mL, 74 mmol) was added through the
addition funnel at such a rate as to maintain the internal temperature below 113 °C (8 min). Vigorous bubbling was observed during the addition of POCl₃. Following this addition, the reaction mixture was heated for an additional 3 h at reflux. Heat was then removed from the flask, and the reaction was stirred at room temperature for 18 h. The reaction mixture was then poured onto ice-water (100 mL), shaken in a separatory funnel, and filtered through a pad of Celite*. The organic layer was collected from the filtrate, and the aqueous layer was extracted twice with ether. All organic fractions were combined, dried over Na₂SO₄, and concentrated in vacuo. Heptane was added to the residue, the contents were filtered through a pad of Celite*, and concentrated in vacuo to give the title compound (1.1 g, 49%) as a brown rod-like crystals in sufficient purity for the next step. 'H NMR (DMSO-d₆; 400 MHz): δ 2.5 (s, 3). ¹³C NMR (DMSO-
d₆; 100.6 MHz): δ 27.04, 127.0, 153.6, 170.8.

When $R^3 = H$ or $OH$, the compounds of Formula I can be modified further to give alternative $R^3$ groups e.g.:

- $R^3 = OH$
- $R^3 = \text{halogen or OTf}$
- $R^3 = H$
- $R^3 = \text{B(OMe)$_2$}$

Followed by coupling reactions (e.g., Suzuki, Stille coupling)
