TITLE OF THE INVENTION

FACTOR XIa INHIBITORS

BACKGROUND OF THE INVENTION

5 Factor XIa is a plasma serine protease involved in the regulation of blood coagulation. While blood coagulation is a necessary and important part of the regulation of an organism's homeostasis, abnormal blood coagulation can also have deleterious effects. For instance, thrombosis is the formation or presence of a blood clot inside a blood vessel or cavity of the heart. Such a blood clot can lodge in a blood vessel, blocking circulation and inducing a heart attack or stroke. Thromboembolic disorders are the largest cause of mortality and disability in the industrialized world.

Blood clotting is a process of control of the blood stream essential for the survival of mammals. The process of clotting, and the subsequent dissolution of the clot after wound healing has taken place, commence after vascular damage, and can be divided into four phases. 15 The first phase, vasoconstriction or vasocontraction, can cause a decrease in blood loss in the damaged area. In the next phase, platelet activation by thrombin, platelets attach to the site of the vessel wall damage and form a platelet aggregate. In the third phase, formation of clotting complexes leads to massive formation of thrombin, which converts soluble fibrinogen to fibrin by cleavage of two small peptides. In the fourth phase, after wound healing, the thrombus is dissolved by the action of the key enzyme of the endogenous fibrinolysis system, plasmin. 20

Two alternative pathways can lead to the formation of a fibrin clot, the intrinsic and the extrinsic pathway. These pathways are initiated by different mechanisms, but in the later phase they converge to give a common final path of the clotting cascade. In this final path of clotting, clotting factor X is activated. The activated factor X is responsible for the formation of thrombin from the inactive precursor prothrombin circulating in the blood. The formation of a thrombus on the bottom of a vessel wall abnormality without a wound is the result of the intrinsic pathway. Fibrin clot formation as a response to tissue damage or an injury is the result of the extrinsic pathway. Both pathways comprise a relatively large number of proteins, which are known as clotting factors. The intrinsic pathway requires the clotting factors V, VIII, IX, X, 25 XI and XII and also prekallikrein, high molecular weight kininogen, calcium ions and phospholipids from platelets. The activation of factor XIa is a central point of intersection between the two pathways of activation of clotting. Factor XIa has an important role in blood clotting. 30

Coagulation is initiated when blood is exposed to artificial surfaces (e.g., during

hemodialysis, "on-pump" cardiovascular surgery, vessel grafts, bacterial sepsis), on cell surfaces, cellular receptors, cell debris, DNA, RNA, and extracellular matrices. This process is also termed contact activation. Surface absorption of factor XII leads to a conformational change in the factor XII molecule, thereby facilitating activation to proteolytic active factor XII molecules (factor XIIa and factor XIIif). Factor XIIa (or XIIif) has a number of target proteins, including plasma prekallikrein and factor XI. Active plasma Kallikrein further activates factor XII, leading to an amplification of contact activation. Alternatively, the serine protease polylcarboxylpeptidase can activate plasma Kallikrein complexed with high molecular weight kininogen in a multiportion complex formed on the surface of cells and matrices (Shariat-Madar et al., Blood, 108:192-199 (2006)). Contact activation is a surface mediated process responsible in part for the regulation of thrombosis and inflammation, and is mediated, at least in part, by fibrinolytic-, complement-, kininogen/kinin-, and other humoral and cellular pathways (for review, Coleman, R., "Contact Activation Pathway", Hemostasis and Thrombosis, pp. 103-122, Lippincott Williams & Wilkins (2001); Schmaier, A.H., "Contact Activation", Thrombosis and Hemorrhage, pp. 105-128 (1998)). The biological relevance of the contact activation system for thromboembolic diseases is supported by the phenotype of factor XII deficient mice. More specifically, factor XII deficient mice were protected from thrombotic vascular occlusion in several thrombosis models as well as stroke models and the phenotype of the XII deficient mice was identical to XI deficient mice (Renne et al., J Exp. Med., 202:271-281 (2005); Kleinschmitz et al., J Exp. Med., 203:513-518 (2006)). The fact that factor XI is downstream from factor XIIa, combined with the identical phenotype of the XII and XI deficient mice suggest that the contact activation system could play a major role in factor XI activation in vivo.

Plasma Kallikrein is a zymogen of a trypsin-like serine protease and is present in plasma. The gene structure is similar to that of factor XI. Overall, the amino acid sequence of plasma Kallikrein has 58% homology to factor XI. Proteolytic activation by factor XIIa at an internal I 389-R390 bond yields a heavy chain (371 amino acids) and a light chain (248 amino acids). The active site of plasma Kallikrein is contained in the light chain. The light chain of plasma Kallikrein reacts with protease inhibitors, including alpha 2 macroglobulin and C1-inhibitor. Interestingly, heparin significantly accelerates the inhibition of plasma Kallikrein by antithrombin III in the presence of high molecular weight kininogen (HMWK). In blood, the majority of plasma Kallikrein circulates in complex with HMWK. Plasma Kallikrein cleaves HMWK to liberate bradykinin. Bradykinin release results in increase of vascular permeability and vasodilation (for review, Coleman, R., "Contact Activation Pathway", Hemostasis and Thrombosis, pp. 103-122, Lippincott Williams & Wilkins (2001); Schmaier A.H., "Contact

Activation", Thrombosis and Hemorrhage, pp. 105-128 (1998)).

Patients presenting genetic deficiency on C1-esterase inhibitor suffer from hereditary angioedema (HAE), a lifelong disease that results in intermittent swelling throughout the body, including the hands, feet, face, throat, genitals and gastrointestinal tract. Analysis of blisters arising from acute episodes have been shown to contain high levels of plasma Kallikrein, and treatment with a protein-based reversible plasma Kallikrein inhibitor, Ecallantide (Kalbitor), has been approved by the FDA for the treatment of acute attacks of HAE (Schneider, L, *et al.*, J.Allergy Clin.Immunol., 120: p.416 (2007)).

Additionally, the plasma Kallikrein-kinin system is abnormally abundant in patients diagnosed with advanced diabetic macular edema (DME). Recent publications have shown that plasma Kallikrein contributes to observed retinal vascular leakage and dysfunction in diabetic rodent models (A. Clermont, *et al.*, Diabetes, 60:1590 (2011)), and that treatment with a small molecule plasma Kallikrein inhibitor ameliorated the observed retinal vascular permeability and other abnormalities related to retinal blood flow.

Factor XIa inhibitor compounds are described in WO2014160592, WO2013022814, WO 2013022814, WO 2013022818, WO 2013055984, WO2013056034, WO2013056060, WO2013118805, WO2013093484, WO2002042273, WO2002037937, WO2002060894, WO2003015715, WO2004002405, US20040180855, WO2004080971, WO2004094372, US20050228000, US20050282805, WO2005123680, US20090036438, US20120088758, US20060074103, WO2006062972, WO2006076246, US20060154915, US20090062287, US20060183771, WO2007070818, WO2007070816, WO2007070826, WO2008076805, WO2008157162, WO2009114677, WO2011100402, and WO2011100401.

The compounds of the present invention may be administered in the form of a pharmaceutically acceptable salt. The term "pharmaceutically acceptable salt" refers to salts prepared from pharmaceutically acceptable non-toxic bases or acids including inorganic or organic bases and inorganic or organic acids. Salts of basic compounds encompassed within the term "pharmaceutically acceptable salt" refer to non-toxic salts of the compounds of this invention which are generally prepared by reacting the free base with a suitable organic or inorganic acid. These salts can be obtained by known methods, for example, by mixing a compound of the present invention with an equivalent amount and a solution containing a desired acid, base, or the like, and then collecting the desired salt by filtering the salt or distilling 15 off the solvent. The compounds of the present invention and salts thereof may form solvates with a solvent such as water, ethanol, or glycerol. The compounds of the present invention may form an acid addition salt and a salt with a base at the same time according to the type of substituent of the side chain.

If the compounds of Formula I, Formula Ia or Formula Ib simultaneously contain 20 acidic and basic groups in the molecule the invention also includes, in addition to the salt forms mentioned, inner salts or betaines (zwitterions).

The present invention encompasses all stereoisomeric forms of the compounds of Formula I, Formula Ia and Formula Ib. Unless a specific stereochemistry is indicated, the present invention is meant to comprehend all such isomeric forms of these compounds. Centers of 25 asymmetry that are present in the compounds of Formula I, Formula Ia and Formula Ib can all independently of one another have (R) configuration or (S) configuration. When bonds to the chiral carbon are depicted as straight lines in the structural Formulas of the invention, it is understood that both the (R) and (S) configurations of the chiral carbon, and hence both enantiomers and mixtures thereof, are embraced within the Formula. When a particular 30 configuration is depicted, that enantiomer (either (R) or (S), at that center) is intended. Similarly, when a compound name is recited without a chiral designation for a chiral carbon, it is understood that both the (R) and (S) configurations of the chiral carbon, and hence individual enantiomers and mixtures thereof, are embraced by the name. The production of specific stereoisomers or mixtures thereof may be identified in the Examples where such stereoisomers or

mixtures were obtained, but this in no way limits the inclusion of all stereoisomers and mixtures thereof from being within the scope of this invention.

The invention includes all possible enantiomers and diastereomers and mixtures of two or more stereoisomers, for example mixtures of enantiomers and/or diastereomers, in all ratios. Thus, enantiomers are a subject of the invention in enantiomerically pure form, both as
5 levorotatory and as dextrorotatory antipodes, in the form of racemates and in the form of mixtures of the two enantiomers in all ratios. In the case of a cis/trans isomerism the invention includes both the cis form and the transform as well as mixtures of these forms in all ratios. The preparation of individual stereoisomers can be carried out, if desired, by separation of a mixture
10 by customary methods, for example by chromatography or crystallization, by the use of stereochemically uniform starting materials for the synthesis or by stereoselective synthesis. Optionally a derivatization can be carried out before a separation of stereoisomers. The separation of a mixture of stereoisomers can be carried out at an intermediate step during the synthesis of a compound of Formula I, Formula Ia or Formula Ib or it can be done on a final
15 racemic product. Absolute stereochemistry may be determined by X-ray crystallography of crystalline products or crystalline intermediates which are derivatized, if necessary, with a reagent containing a stereogenic center of known configuration. Where compounds of this invention are capable of tautomerization, all individual tautomers as well as mixtures thereof are included in the scope of this invention. The present invention includes all such isomers, as well
20 as salts, solvates (including hydrates) and solvated salts of such racemates, enantiomers, diastereomers and tautomers and mixtures thereof.

In the compounds of the invention, the atoms may exhibit their natural isotopic abundances, or one or more of the atoms may be artificially enriched in a particular isotope having the same atomic number, but an atomic mass or mass number different from the atomic
25 mass or mass number predominantly found in nature. The present invention is meant to include all suitable isotopic variations of the specifically and generically described compounds. For example, different isotopic forms of hydrogen (H) include protium (^1H) and deuterium (^2H). Protium is the predominant hydrogen isotope found in nature. Enriching for deuterium may afford certain therapeutic advantages, such as increasing *in vivo* half-life or reducing dosage
30 requirements, or may provide a compound useful as a standard for characterization of biological samples. Isotopically-enriched compounds can be prepared without undue experimentation by conventional techniques well known to those skilled in the art or by processes analogous to those described in the general process schemes and examples herein using appropriate isotopically-enriched reagents and/or intermediates.

When any variable (e.g. R^4 , etc.) occurs more than one time in any constituent, its definition on each occurrence is independent at every other occurrence. Also, combinations of substituents and variables are permissible only if such combinations result in stable compounds. Lines drawn into the ring systems from substituents represent that the indicated bond may be attached to any of the substitutable ring atoms. If the ring system is bicyclic, it is intended that the bond be attached to any of the suitable atoms on either ring of the bicyclic moiety.

It is understood that one or more silicon (Si) atoms can be incorporated into the compounds of the instant invention in place of one or more carbon atoms by one of ordinary skill in the art to provide compounds that are chemically stable and that can be readily synthesized by techniques known in the art from readily available starting materials. Carbon and silicon differ in their covalent radius leading to differences in bond distance and the steric arrangement when comparing analogous C-element and Si-element bonds. These differences lead to subtle changes in the size and shape of silicon-containing compounds when compared to carbon. One of ordinary skill in the art would understand that size and shape differences can lead to subtle or dramatic changes in potency, solubility, lack off-target activity, packaging properties, and so on. (Diass, J. O. *et al.* *Organometallics* (2006) 5:1188-1198; Showell, G.A. *et al.* *Bioorganic & Medicinal Chemistry Letters* (2006) 16:2555-2558).

It is understood that substituents and substitution patterns on the compounds of the instant invention can be selected by one of ordinary skill in the art to provide compounds that are chemically stable and that can be readily synthesized by techniques known in the art, as well as those methods set forth below, from readily available starting materials. If a substituent is itself substituted with more than one group, it is understood that these multiple groups may be on the same carbon or on different carbons, so long as a stable structure results. The phrase “optionally substituted” (with one or more substituents) should be understood as meaning that the group in question is either unsubstituted or may be substituted with one or more substituents.

Furthermore, compounds of the present invention may exist in amorphous form and/or one or more crystalline forms, and as such all amorphous and crystalline forms and mixtures thereof the compounds of Formula I, Formula Ia and Formula Ib are intended to be included within the scope of the present invention. In addition, some of the compounds of the instant invention may form solvates with water (i.e., a hydrate) or common organic solvents. Such solvates and hydrates, particularly the pharmaceutically acceptable solvates and hydrates, of the instant compounds are likewise encompassed within the scope of this invention, along with un-solvated and anhydrous forms.

Reference to the compounds of this invention as those of a specific formula or embodiment, e.g., Formula I, Formula Ia or Formula Ib or any other generic structural formula or specific compound described or claimed herein, is intended to encompass the specific compound or compounds falling within the scope of the formula or embodiment, including salts thereof, particularly pharmaceutically acceptable salts, solvates of such compounds and solvated salt forms thereof, where such forms are possible unless specified otherwise.

Also, in the case of a carboxylic acid (-COOH) or alcohol group being present in the compounds of the present invention, pharmaceutically acceptable esters of carboxylic acid derivatives, such as methyl, ethyl, or pivaloyloxymethyl, or acyl derivatives of alcohols, such as *O*-acetyl, *O*-pivaloyl, *O*-benzoyl, and *O*-aminoacyl, can be employed. Included are those esters and acyl groups known in the art for modifying the solubility or hydrolysis characteristics for use as sustained-release or prodrug formulations.

Any pharmaceutically acceptable pro-drug modification of a compound of this invention which results in conversion in vivo to a compound within the scope of this invention is also within the scope of this invention. For example, esters can optionally be made by esterification of an available carboxylic acid group or by formation of an ester on an available hydroxy group in a compound. Similarly, labile amides can be made. Pharmaceutically acceptable esters or amides of the compounds of this invention may be prepared to act as pro-drugs which can be hydrolyzed back to an acid (or -COO⁻ depending on the pH of the fluid or tissue where conversion takes place) or hydroxy form particularly in vivo and as such are encompassed within the scope of this invention. Examples of pharmaceutically acceptable pro-drug modifications include, but are not limited to, -C₁₋₆alkyl esters and -C₁₋₆alkyl substituted with phenyl esters.

Accordingly, the compounds within the generic structural formulas, embodiments and specific compounds described and claimed herein encompass salts, all possible stereoisomers and tautomers, physical forms (e.g., amorphous and crystalline forms), solvate and hydrate forms thereof and any combination of these forms, as well as the salts thereof, pro-drug forms thereof, and salts of pro-drug forms thereof, where such forms are possible unless specified otherwise.

Anticoagulant therapy is indicated for the treatment and prevention of a variety of thrombotic conditions, particularly coronary artery and cerebrovascular disease. Those
5 experienced in this field are readily aware of the circumstances requiring anticoagulant therapy. The term “patient” used herein is taken to mean mammals such as primates, humans, sheep, horses, cattle, pigs, dogs, cats, rats, and mice.

Factor XIa or dual Factor XIa/plasma Kallikrein inhibition are useful not only in the anticoagulant therapy of individuals having thrombotic conditions, but are useful whenever
10 inhibition of blood coagulation is required such as to prevent coagulation of stored whole blood and to prevent coagulation in other biological samples for testing or storage. Thus, the Factor XIa or dual Factor XIa/plasma Kallikrein inhibitors can be added to or contacted with any medium containing or suspected of containing thrombin and in which it is desired that blood coagulation be inhibited, e.g., when contacting the mammal’s blood with material selected from
15 the group consisting of vascular grafts, stents, orthopedic prosthesis, cardiac prosthesis, and extracorporeal circulation systems.

Compounds of the invention may be useful for treating or preventing venous thromboembolism (e.g., obstruction or occlusion of a vein by a detached thrombus; obstruction or occlusion of a lung artery by a detached thrombus), cardiogenic thromboembolism (e.g.,
20 obstruction or occlusion of the heart by a detached thrombus), arterial thrombosis (e.g., formation of a thrombus within an artery that may cause infarction of tissue supplied by the artery), atherosclerosis (e.g., arteriosclerosis characterized by irregularly distributed lipid deposits) in mammals, and for lowering the propensity of devices that come into contact with blood to clot blood.

25 Examples of venous thromboembolism which may be treated or prevented with compounds of the invention include obstruction of a vein, obstruction of a lung artery (pulmonary embolism), deep vein thrombosis, thrombosis associated with cancer and cancer chemotherapy, thrombosis inherited with thrombophilic diseases such as Protein C deficiency, Protein S deficiency, antithrombin III deficiency, and Factor V Leiden, and thrombosis resulting
30 from acquired thrombophilic disorders such as systemic lupus erythematosus (inflammatory connective tissue disease). Also with regard to venous thromboembolism, compounds of the invention may be useful for maintaining patency of indwelling catheters.

neurological affliction related to impaired cerebral blood supply), cardiogenic thromboembolism associated with atrial fibrillation (rapid, irregular twitching of upper heart chamber muscular fibrils), cardiogenic thromboembolism associated with prosthetic heart valves such as mechanical heart valves, and cardiogenic thromboembolism associated with heart disease.

Oral administration is preferred. Coating of stents with compounds of the Formula (I) and other surfaces which come into contact with blood in the body is possible.

25 The invention also relates to a process for the production of a medicament, which comprises bringing at least one compound of the Formula (I) into a suitable administration form using a pharmaceutically suitable and pharmaceutically acceptable carrier and optionally further suitable active substances, additives or auxiliaries.

30 Suitable solid or galenical preparation forms are, for example, granules, powders, coated tablets, tablets, (micro)capsules, suppositories, syrups, juices, suspensions, emulsions, drops or injectable solutions and preparations having prolonged release of active substance, in whose preparation customary excipients such as vehicles, disintegrants, binders, coating agents, swelling agents, glidants or lubricants, flavorings, sweeteners and solubilizers are used. Frequently used auxiliaries which may be mentioned are magnesium carbonate, titanium dioxide, lactose, mannitol and other sugars, talc, lactose, gelatin, starch, cellulose and its derivatives, animal and plant oils such as cod liver oil, sunflower, peanut or sesame oil, polyethylene glycol and solvents such as, for example, sterile water and mono- or polyhydric alcohols such as

glycerol.

The dosage regimen utilizing the Factor XIa inhibitors or dual Factor XIa/plasma Kallikrein inhibitors is selected in accordance with a variety of factors including type, species, age, weight, sex and medical condition of the patient; the severity of the condition to be treated; the route of administration; the renal and hepatic function of the patient; and the particular compound or salt thereof employed. An ordinarily skilled physician or veterinarian can readily determine and prescribe the effective amount of the drug required to prevent, counter, or arrest the progress of the condition.

Oral dosages of the Factor XIa inhibitors or dual Factor XIa/plasma Kallikrein inhibitors, when used for the indicated effects, will range between about 0.01 mg per kg of body weight per day (mg/kg/day) to about 30 mg/kg/day, preferably 0.025-7.5 mg/kg/day, more preferably 0.1-2.5 mg/kg/day, and most preferably 0.1-0.5 mg/kg/day (unless specified otherwise, amounts of active ingredients are on free base basis). For example, an 80 kg patient would receive between about 0.8 mg/day and 2.4 g/day, preferably 2-600 mg/day, more preferably 8-200 mg/day, and most preferably 8-40 mg/kg/day. A suitably prepared medicament for once a day administration would thus contain between 0.8 mg and 2.4 g, preferably between 2 mg and 600 mg, more preferably between 8 mg and 200 mg, and most preferably 8 mg and 40 mg, e.g., 8 mg, 10 mg, 20 mg and 40 mg. Advantageously, the Factor XIa inhibitors may be administered in divided doses of two, three, or four times daily. For administration twice a day, a suitably prepared medicament would contain between 0.4 mg and 4 g, preferably between 1 mg and 300 mg, more preferably between 4 mg and 100 mg, and most preferably 4 mg and 20 mg, e.g., 4 mg, 5 mg, 10 mg and 20 mg.

Intravenously, the patient would receive the active ingredient in quantities sufficient to deliver between 0.025-7.5 mg/kg/day, preferably 0.1-2.5 mg/kg/day, and more preferably 0.1-0.5 mg/kg/day. Such quantities may be administered in a number of suitable ways, e.g. large volumes of low concentrations of active ingredient during one extended period of time or several times a day, low volumes of high concentrations of active ingredient during a short period of time, e.g. once a day. Typically, a conventional intravenous formulation may be prepared which contains a concentration of active ingredient of between about 0.01-1.0 mg/ mL, e.g. 0.1 mg/ mL, 0.3 mg/ mL, and 0.6 mg/ mL, and administered in amounts per day of between 0.01 mL/kg patient weight and 10.0 mL/kg patient weight, e.g. 0.1 mL/kg, 0.2 mL/kg, 0.5 mL/kg. In one example, an 80 kg patient, receiving 8 mL twice a day of an intravenous formulation having a concentration of active ingredient of 0.5 mg/ mL, receives 8 mg of active ingredient per day. Glucuronic acid, L-lactic acid, acetic acid, citric acid or any pharmaceutically

acceptable acid/conjugate base with reasonable buffering capacity in the pH range acceptable for intravenous administration may be used as buffers. The choice of appropriate buffer and pH of a formulation, depending on solubility of the drug to be administered, is readily made by a person having ordinary skill in the art.

5 Compounds of the Formula I, Formula Ia and Formula Ib can be administered both as a monotherapy and in combination with other therapeutic agents, including antithrombotics (anticoagulants and platelet aggregation inhibitors), thrombolytics (plasminogen activators), other profibrinolytically active substances, hypotensives, blood sugar regulators, lipid-lowering agents and antiarrhythmics.

10 The Factor XIa inhibitors or dual Factor XIa/plasma Kallikrein inhibitors can also be co-administered with suitable anticoagulants, including, but not limited to, other Factor XIa inhibitors, thrombin inhibitors, thrombin receptor antagonists, factor VIIa inhibitors, factor Xa inhibitors, factor IXa inhibitors, factor XIIa inhibitors, adenosine diphosphate antiplatelet agents (e.g., P2Y12 antagonists), fibrinogen receptor antagonists (e.g. to treat or prevent unstable
15 angina or to prevent reocclusion after angioplasty and restenosis), other anticoagulants such as aspirin, and thrombolytic agents such as plasminogen activators or streptokinase to achieve synergistic effects in the treatment of various vascular pathologies. Such anticoagulants include, for example, apixaban, dabigatran, cangrelor, ticagrelor, vorapaxar, clopidogrel, edoxaban, mipomersen, prasugrel, rivaroxaban, and semuloparin. For example, patients suffering from
20 coronary artery disease, and patients subjected to angioplasty procedures, would benefit from coadministration of fibrinogen receptor antagonists and thrombin inhibitors. Factor XIa inhibitors may be administered first following thrombus formation, and tissue plasminogen activator or other plasminogen activator is administered thereafter.

 Alternatively or additionally, one or more additional pharmacologically active
25 agents may be administered in combination with a compound of the invention. The additional active agent (or agents) is intended to mean a pharmaceutically active agent (or agents) that is active in the body, including pro-drugs that convert to pharmaceutically active form after administration, which is different from the compound of the invention, and also includes free-acid, free-base and pharmaceutically acceptable salts of said additional active agents when such

patient in one or more separate dosage formulations which allows for concurrent or sequential administration of the active agents (co-administration of the separate active agents). Trademark names of pharmaceutical drugs noted above are provided for exemplification of the marketed form of the active agent(s); such pharmaceutical drugs could be used in a separate dosage form for concurrent or sequential administration with a compound of the invention, or the active agent(s) therein could be used in a fixed dose drug combination including a compound of the invention.

Typical doses of Factor XIa inhibitors or Factor XIa/plasma Kallikrein inhibitors of the invention in combination with other suitable anti-platelet agents, anticoagulation agents, or thrombolytic agents may be the same as those doses of Factor XIa inhibitors administered without coadministration of additional anti-platelet agents, anticoagulation agents, or thrombolytic agents, or may be substantially less than those doses of thrombin inhibitors administered without coadministration of additional anti-platelet agents, anticoagulation agents, or thrombolytic agents, depending on a patient's therapeutic needs.

The compounds are administered to a mammal in a therapeutically effective amount. By "therapeutically effective amount" it is meant an amount of a compound of the present invention that, when administered alone or in combination with an additional therapeutic

agent to a mammal, is effective to treat (i.e., prevent, inhibit or ameliorate) the thromboembolic and/or inflammatory disease condition or treat the progression of the disease in a host.

The compounds of the invention are preferably administered alone to a mammal in a therapeutically effective amount. However, the compounds of the invention can also be administered in combination with an additional therapeutic agent, as defined below, to a mammal in a therapeutically effective amount. When administered in a combination, the combination of compounds is preferably, but not necessarily, a synergistic combination. Synergy, as described for example by Chou and Talalay, *Adv. Enzyme Regul.* 1984, 22, 27-55, occurs when the effect (in this case, inhibition of the desired target) of the compounds when administered in combination is greater than the additive effect of each of the compounds when administered individually as a single agent. In general, a synergistic effect is most clearly demonstrated at suboptimal concentrations of the compounds. Synergy can be in terms of lower cytotoxicity, increased anticoagulant effect, or some other beneficial effect of the combination compared with the individual components.

By “administered in combination” or “combination therapy” it is meant that the compound of the present invention and one or more additional therapeutic agents are administered concurrently to the mammal being treated. When administered in combination each component may be administered at the same time or sequentially in any order at different points in time. Thus, each component may be administered separately but sufficiently closely in time so as to provide the desired therapeutic effect.

The present invention is not limited in scope by the specific embodiments disclosed in the examples which are intended as illustrations of a few aspects of the invention and any embodiments that are functionally equivalent are within the scope of this invention. Indeed, various modifications of the invention in addition to those shown and described herein will become apparent to those skilled in the relevant art and are intended to fall within the scope of the appended claims.

GENERAL SCHEMES

Compounds of the present invention may be prepared using conventional techniques or according to the methodology outlined in the following general synthetic schemes.

20 Multiple embodiments of the present invention are summarized in Scheme 1 which depicts the preparation of compounds I and II from intermediate 1a, synthesized from the Negishi cross coupling reaction of two readily available compounds in the presence of a catalyst such as tetrakis(triphenylphosphine)palladium(0) in a solvent such as tetrahydrofuran at elevated temperatures. Alkylation of intermediate 1b by a base such as lithium diisopropylamide and allyl bromide affords intermediate 1b. Intermediate 1d is prepared by a palladium catalyzed Suzuki-Miyaura coupling of intermediate 1b and a boronate or boronic acid 1c in the presence of a precatalyst such as chloro(2-dicyclohexylphosphino-2',4',6'-tri-*i*-propyl-1,1'-biphenyl)[2-(2-aminoethyl)phenyl] palladium(II) methyl-*tert*-butyl ether adduct and a base such as potassium phosphate in a mixture of water and another solvent such as THF or dioxane at elevated

25 temperatures. Protection of the hydroxyl group of intermediate 1d by a protection group such as a *tert*-butyldiphenylsilyl group followed by an amide coupling of 1e with 3-butenic acid or a substituted 3-butenic acid leads to intermediate 1f. Intramolecular olefin metathesis of 1f mediated by a catalyst such as Zhan catalyst-1B in a solvent such as toluene or dichloroethane at ambient or elevated temperatures closes the ring; deprotection *in situ* or after workup provides

30

intermediate 1g. Transformation of the phenol to a phenyl triflate 1h followed by another palladium catalyzed Suzuki-Miyaura coupling with a boronate or boronic acid affords compound I. Alternatively, compound I can be synthesized by a one-pot-two-step transformation of the triflate 1h to a boronic acid in the presence of a palladium catalyst followed by a subsequent Suzuki-Miyaura coupling with an aryl halide or triflate. A final oxidation of compound I by an oxidant such as mCPBA, peracetic acid or oxone in a solvent such as acetic acid or dichloromethane at ambient temperature finishes pyridine N-oxide II.

Scheme 1

Representative macrocycles with an imidazole B ring of this invention can be prepared as shown in Scheme 2. Deprotonation of *para*-methoxybenzyl protected 2-methyl-5-hydroxypyridine 2a with a base such as lithium diisopropylamide followed by quenching with diethyl carbonate affords ester 2b. Allylation of 2b in the presence of a base and allyl bromide, followed by saponification by a base such as lithium hydroxide generates carboxylic acid 2d. Reaction of 2d with an alpha-bromo ketone 2e mediated by a base such as cesium carbonate in a solvent such as DMF provides intermediate 2f. Condensation of 2f with excess amount of ammonium acetate in a solvent such as toluene or a mixed solvent of toluene and acetic acid at elevated temperatures affords imidazole 2g. Protection of the imidazole NH with a SEM group and conversion of the bromo to an amino group employing a copper precatalyst such as copper

(I) iodide and a ligand such as L-proline gives intermediate 2i. The synthesis of III is accomplished by following the subsequent steps described in Scheme 1.

Scheme 2

5 More generally, representative macrocycles containing a phenyl, substituted phenyl, 5/6 membered heterocycle or substituted 5/6membered heterocycle B ring can be prepared as shown in Scheme 3. Suzuki-Miyaura coupling of intermediate ketone 3a with a boronic acid or ester 3b in the presence of a palladium precatalyst such as PdCl₂(dppf) and a base such as potassium phosphate in a mixed solvent of water and dioxane or THF at elevated

10 temperatures provide 3c. Amide bond formation between 3c and (4-carboxybutyl)triphenylphosphonium bromide mediated by a peptide coupling reagent such as HATU affords 3d, which upon treatment with excess equivalents of a base such as LHMDS in a solvent such as THF at a concentration equal or lower than about 0.02 M at rt provides 3e. Selective hydrogenation of the alkene in the presence of a chloropyridine moiety catalyzed by

15 either Raney nickel or vanadium contaminated platinum on carbon gives 3f. The synthesis of compound III is accomplished by the subsequent Suzuki-Miyaura coupling of 3f with a boronic acid or ester. Alternatively, 3f can be converted to a boronic acid or ester, which reacts with an aryl halide or triflate in the presence of a catalyst to afford compound III. In cases where X₂ is an alkoxyl group, it is transformed to the corresponding triflate before the Suzuki-Miyaura

20 coupling. Oxidation of IV to N-oxide V is described in Scheme 3.

Scheme 3

The intermediate ketone 3a can be prepared as shown in Scheme 4. Carboxylic acid (4a), commercially available or synthesized from commercially available materials, is converted to the corresponding Weinreb amide in the presence of a peptide coupling reagent to afford 4b. Alternatively, 4b can be synthesized from the reaction of an ester (4a) with N,O-dimethylhydroxylamine and a suitable organomagnesium reagent or lithium amide base. (*Tetrahedron Lett.* **1995**, 36, 5461-5464.) Weinreb amide 4b was treated with the anion generated from metal-halogen exchange of substituted 2-bromopyridine (4c) and a strong base such as *n*-BuLi provides the corresponding ketone 3a.

Scheme 4

Alternatively, ketone 3a can be made from the reaction of the Weinreb amide of a 4-substituted picolinic acid (5b) with an organometallic nucleophile (5a) generated by
15 deprotonation or metal-halogen exchange of the corresponding arene or heterarene with an organometallic base such as *n*-BuLi (Scheme 5).

In another embodiment of the invention, macrocycles with general structures V and VI can be prepared from intermediate 1d as shown in Scheme 6. Reaction of aniline 1d with ethyl 2-oxoacetate and allyltributyltin in the presence of a mild acid such as maleic acid (Zhao *et al.*, *Synthesis* 2006, 19, 3189.) affords 6a. Protection of the hydroxyl group with TBDPS followed by a ring closure metathesis reaction catalyzed by a ruthenium catalyst such as Zhan's catalyst and removal of TBDPS protection provides 6c. Hydrogenation of 6c and conversion of the hydroxyl group to a triflate afford 6e. Suzuki-Miyaura coupling of 6e with a boronic acid or ester gives intermediate 6f. Protection of the aniline with a trifluoroacetyl group followed by oxidation of pyridine by an oxidant such as mCPBA or peracetic acid affords pyridine N-oxide 6h. The treatment of 6h with a base such as lithium hydroxide in a mixed solvent of water, methanol and THF at elevated temperature causes hydrolysis of the ethyl ester and removal of the trifluoroacetyl protection on the aniline to afford amino acid V. Compound VI can be prepared by coupling of V with an amine in the presence of a peptide coupling reagent such as HATU.

Separation of diastereomers can be carried out at various stages in the preparation of the desired final compounds; however, it is typically carried out on the final products using supercritical fluid chromatography (SFC). Separation of enantiomers is achieved by SFC employing various chiral columns. The absolute configuration is assigned either directly by X-ray co-crystal structures or by comparison of the FXIa K_i values between one pair of enantiomers based on the assumption that compounds with certain configuration are more potent than their corresponding enantiomer.

Preparative thin layer chromatography (PTLC) was performed on 20 x 20cm plates (500 μm – 1500 μm thick silica gel). Flash column chromatography was conducted on ISCO flash chromatography systems using columns pre-packed with silica gel, eluting with hexanes/ethyl acetate or DCM/MeOH gradient unless noted otherwise.

INTERMEDIATES

INTERMEDIATE 1

6-(1-(3-CHLOROPHENYL)BUT-3-EN-1-YL)PYRIDIN-3-OL

Step A: 6-(3-Chlorobenzyl)pyridin-3-ol: To a clean, dry 500 mL round bottom flask charged with a magnetic stirring bar was added 2-bromo-5-hydroxypyridine (4.2 g, 24.14 mmol) and tetrakis(triphenylphosphine)palladium(0) (2.79 g, 2.414 mmol). It was sealed by a rubber septum and purged with nitrogen three times. To the flask was transferred THF (degassed, 100 mL) through a cannula and it was stirred to form a solution. To the solution was transferred 3-chlorobenzylzinc chloride (0.5 M in THF, 100 mL, 50.0 mmol) through a cannula. The flask was merged into a pre-heated oil bath at 65°C and stirred for 4 h. It was allowed to cool to rt and aged overnight. The reaction was quenched with ammonium chloride (50 mL) and brine (50 mL). The mixture was extracted with ethyl acetate (100 mL). The organic layer was separated and dried over sodium sulfate, filtered and concentrated. The residue was triturated in DCM (50 mL), filtered and rinsed with DCM (2x10 mL) to afford the title compound. MS (ES⁺) *m/z*: 220 (M+H).

Step B: 5-(2-Chloro-5-nitrophenyl)dihydrofuran-2(3H)-one: To a solution of 6-(3-chlorobenzyl)pyridin-3-ol (1.4 g, 6.37 mmol) in THF (40 mL) at -78°C was added a solution of LDA (2 M in THF, 8.60 mL, 17.21 mmol). Factor XIa assay

The effectiveness of a compound of the present invention as an inhibitor of Coagulation Factor XIa can be determined using a relevant purified serine protease, and an appropriate synthetic substrate. The rate of hydrolysis of the chromogenic or fluorogenic substrate by the relevant serine protease was measured both in the absence and presence of compounds of the present invention. Assays were conducted at rt or at 37°C. Hydrolysis of the substrate resulted in release of amino trifluoromethylcoumarin (AFC), which was monitored spectrofluorometrically by measuring the increase in emission at 510 nm with excitation at 405 nm. A decrease in the rate of fluorescence change in the presence of inhibitor is indicative of

enzyme inhibition. Such methods are known to one skilled in the art. The results of this assay are expressed as the inhibitory constant, K_i .

Factor XIa determinations were made in 50mM HEPES buffer at pH 7.4 containing 150 mM NaCl, 5 mM CaCl_2 , and 0.1% PEG 8000 (polyethylene glycol; JT Baker or Fisher Scientific). Determinations were made using purified human Factor XIa at a final concentration of 40 pM (Sekisui Diagnostics) and the synthetic substrate, Z-Gly-Pro-Arg-AFC, TFA salt (Sigma #C0980) at a concentration of 100 μM .

Activity assays were performed by diluting a stock solution of substrate at least tenfold to a final concentration $\leq 0.1 K_m$ into a solution containing enzyme or enzyme equilibrated with inhibitor. Times required to achieve equilibration between enzyme and inhibitor were determined in control experiments. Initial velocities of product formation in the absence (V_o) or presence of inhibitor (V_i) were measured. Assuming competitive inhibition, and that unity is negligible compared $K_m/[S]$, $[I]/e$, and $[I]/e$ (where $[S]$, $[I]$, and e respectively represent the total concentrations, of substrate, inhibitor and enzyme), the equilibrium constant (K_i) for dissociation of the inhibitor from the enzyme can be obtained from the dependence of V_o/V_i on $[I]$ shown in the following equation.

$$V_o/V_i = 1 + [I]/K_i$$

The activities shown by this assay indicate that the compounds of the invention may be therapeutically useful for treating or preventing various cardiovascular and/or cerebrovascular thromboembolic conditions in patients suffering from unstable angina, acute coronary syndrome, refractory angina, myocardial infarction, transient ischemic attacks, atrial fibrillation, stroke such as thrombotic stroke or embolic stroke, venous thrombosis, coronary and cerebral arterial thrombosis, cerebral and pulmonary embolism, atherosclerosis, deep vein thrombosis, disseminated intravascular coagulation, and reocclusion or restenosis of recanalized vessels.

Kallikrein assay

The effectiveness of a compound of the present invention as an inhibitor of Kallikrein can be determined using a relevant purified serine protease, and an appropriate synthetic substrate. The rate of hydrolysis of the chromogenic or fluorogenic substrate by the relevant serine protease was measured both in the absence and presence of compounds of the present invention. Assays were conducted at rt or at 37°C. Hydrolysis of the substrate resulted in release of amino trifluoromethylcoumarin (AFC), which was monitored spectrofluorometrically by measuring the increase in emission at 510 nm with excitation at 405 nm. A decrease in the rate of fluorescence change in the presence of inhibitor is indicative of enzyme inhibition. Such methods are known to one skilled in the art. The results of this assay are expressed as the inhibitory constant, K_i.

Kallikrein determinations were made in 50 mM HEPES buffer at pH 7.4 containing 150 mM NaCl, 5 mM CaCl₂, and 0.1% PEG 8000 (polyethylene glycol; Fisher Scientific). Determinations were made using purified Human plasma Kallikrein at a final concentration of 0.5 nM (Enzyme Research Laboratories) and the synthetic substrate, Acetyl-K-P-R-AFC (Sigma # C6608) at a concentration of 100mM.

Activity assays were performed by diluting a stock solution of substrate at least tenfold to a final concentration $\leq 0.2 K_m$ into a solution containing enzyme or enzyme equilibrated with inhibitor. Times required to achieve equilibration between enzyme and inhibitor were determined in control experiments. The reactions were performed under linear progress curve conditions and fluorescence increase measured at 405 Ex/510 Em nm. Values were converted to percent inhibition of the control reaction (after subtracting 100% Inhibition value). IC₅₀ was determined by inflection point from a four parameter logistic curve fit. K_i was calculated using the Cheng Prusoff equation, $K_i = IC_{50}/(1+([S]/K_m))$.

The activities shown by this assay indicate that the compounds of the invention may be therapeutically useful for treating or preventing various cardiovascular and/or cerebrovascular thromboembolic conditions in patients suffering from unstable angina, acute

coronary syndrome, refractory angina, myocardial infarction, transient ischemic attacks, atrial fibrillation, stroke such as thrombotic stroke or embolic stroke, venous thrombosis, coronary and cerebral arterial thrombosis, cerebral and pulmonary embolism, atherosclerosis, deep vein thrombosis, disseminated intravascular coagulation, and reocclusion or restenosis of recanalized vessels.
