TETRAHYDROTRIAZOLOPYRIMIDINE DERIVATIVES AS HUMAN NEUTROPHIL ELASTASE INHIBITORS

Field of the Invention

This invention relates to heterocyclic compounds, which are pyrimidine derivatives having human neutrophil elastase inhibitory properties, and their use in therapy.

Background to the invention

Human neutrophil elastase (HNE) is a 32 kDa serine proteinase found in the azurophilic granules of neutrophils. It has a role in the degradation of a wide range of extracellular matrix proteins, including fibronectin, laminin, proteoglycans, Type III and Type IV collagens as well as elastin (Bieth, G. In *Regulation of Matrix accumulation*, Mecham, R.P. (Eds), Academic Press, NY, USA 1986, 217-306). HNE has long been considered to play an important role in homeostasis through repair and disposal of damaged tissues via degradation of the tissue structural proteins. It is also relevant in the defense against bacterial invasion by means of degradation of the bacterial body. In addition to its effects on matrix tissues, HNE has been implicated in the upregulation of IL-8 gene expression and also induces IL-8 release from the epithelial cells of the lung. In animal models of Chronic Obstructive Pulmonary Disease induced by tobacco smoke exposure both small molecule inhibitors and protein inhibitors of HNE inhibit the inflammatory response and the development of emphysema (Wright, J.L. et al. *Am. J. Respir. Crit. Care Med.* 2002, 166, 954-960; Churg, A. et al. *Am. J. Respir. Crit. Care Med.* 2003, 168, 199-207). Thus, HNE may play a role both in matrix destruction and in amplifying inflammatory responses in chronic respiratory diseases where neutrophil influx is a characteristic feature. Indeed, HNE is believed to play a role in several pulmonary diseases, including chronic obstructive pulmonary disease (COPD), cystic fibrosis (CF), acute respiratory distress
syndrome (ARDS), pulmonary emphysema, pneumonia and lung fibrosis. It is also implicated in several cardiovascular diseases in which tissue remodelling is involved, for example, in heart failure and the generation of ischaemic tissue injury following acute myocardial infarction.

COPD is an umbrella term encompassing three different pathological conditions, all of which contribute to limitation of airflow: chronic bronchitis, emphysema and small-airway disease. Generally all three will exist to varying extents in patients presenting with COPD, and all three may be due to neutrophil-mediated inflammation, as supported by the increased number of neutrophils observed in bronchoalveolar leakage (BAL) fluids of COPD patients (Thompson, A.B.; Daughton, D.; et al. Am. Rev. Respir. Dis. 1989, 140, 1527-1537). The major pathogenic determinant in COPD has long been considered to be the protease-anti-protease balance (also known as the "elastase:anti-elastase hypothesis"), in which an imbalance of HNE and endogenous antiproteases such as a 1-antitrypsin (a1-AT), secretory leukocyte protease inhibitor (SLPI) and pre-elafin leads to the various inflammatory disorders of COPD. Individuals that have a genetic deficiency of the protease inhibitor a 1-antitrypsin develop emphysema that increases in severity over time (Laurrell, C.B.; Eriksson, S Scand. J. Clin. Invest. 1963 15, 132-140). An excess of HNE is therefore destructive, leading to the breakdown of pulmonary morphology with loss of elasticity and destruction of alveolar attachments of airways in the lung (emphysema) whilst simultaneously increasing microvascular permeability and mucus hypersecretion (chronic bronchitis).

Several human neutrophil inhibitors have need disclosed so far in the art. In particular, International Patent Applications n. WO201 1/1 10858 and n. WO201 1/1 10859 describe some pyrimidine derivatives having human neutrophil elastase inhibitory properties and their use in therapy.
Although several HNE inhibitors have been disclosed so far as above reported, there is still a need for further HNE inhibitors. Particularly, there is still a need for further HNE inhibitors endowed with a high potency for HNE enzyme inhibition. Particularly advantageous would also be the identification of further HNE inhibitors endowed with a high potency for HNE enzyme inhibition and which would show an appropriate developability profile as an inhalation treatment.

The present invention addresses the above mentioned need by providing the compounds of the invention.

The weight ratio of the first and second active ingredients may be varied and will depend upon the effective dose of each ingredient. Generally, an effective dose of each will be used.

The magnitude of prophylactic or therapeutic dose of a compound of the invention will, of course, vary with the nature of the severity of the condition to be treated and with the particular compound and its route of administration, and will generally be determined by clinical trial as required in the pharmaceutical art. It will also vary according to the age, weight and response of the individual patient. In general, the daily dose range will lie within the range of from about 0.001 mg to about 100 mg per kg body weight of a
mammal, preferably 0.01 mg to about 50 mg per kg, and most preferably 0.1 to 10 mg per kg, in single or divided doses. On the other hand, it may be necessary to use dosages outside these limits in some cases.

Another aspect of the present invention provides pharmaceutical compositions which comprise a compound of the invention and a pharmaceutically acceptable carrier. The term "composition", as in pharmaceutical composition, is intended to encompass a product comprising the active ingredient(s), and the inert ingredient(s) (pharmaceutically acceptable excipients) that make up the carrier, as well as any product which results, directly or indirectly, from combination, complexation or aggregation of any two or more of the ingredients, or from dissociation of one or more of the ingredients, or from other types of reactions or interactions of one or more of the ingredients. Accordingly, the pharmaceutical compositions of the invention encompass any composition made by admixing a compound of the invention, additional active ingredient(s), and pharmaceutically acceptable excipients.

The pharmaceutical compositions of the invention comprise a compound of the invention as an active ingredient or a pharmaceutically acceptable salt thereof, and may also contain a pharmaceutically acceptable carrier and optionally other therapeutic ingredients. The term "pharmaceutically acceptable salts" refers to salts prepared from pharmaceutically acceptable non-toxic bases or acids including inorganic bases or acids and organic bases or acids.

Any suitable route of administration may be employed for providing a mammal, especially a human, with an effective dosage of a compound of the present invention. In therapeutic use, the active compound may be administered by any convenient, suitable or effective route. Suitable routes of administration are known, and include oral, intravenous, rectal, parenteral,
topical, ocular, nasal, buccal and pulmonary (by inhalation).

Compositions suitable for administration by inhalation are known, and may include carriers and/or diluents that are known for use in such compositions. The composition may contain 0.01-99% by weight of active compound. Preferably, a unit dose comprises the active compound in an amount of 1 µg to 10 mg.

The most suitable dosage level may be determined by any known suitable method. It will be understood, however, that the specific amount for any particular patient will depend upon a variety of factors, including the activity of the specific compound that is used, the age, body weight, diet, general health and sex of the patient, time of administration, the route of administration, the rate of excretion, the use of any other drugs, and the severity of the disease to be treated.

For delivery by inhalation, the active compound is preferably in the form of microparticles. They may be prepared by a variety of techniques, including spray-drying, freeze-drying and micronisation.

By way of example, a composition of the invention may be prepared as a suspension for delivery from a nebuliser or as an aerosol in a liquid propellant, for example for use in a pressurised metered dose inhaler (PMDI).

Propellants suitable for use in a PMDI are known to the skilled person, and include CFC-12, HFA-134a, HFA-227, HCFC-22 (CC12F2) and HFA-152 (CH4F2 and isobutane).

In a preferred embodiment of the invention, a composition of the invention is in dry powder form, for delivery using a dry powder inhaler (DPI). Many types of DPI are known.

Microparticles for delivery by administration may be formulated with excipients that aid delivery and release. For example, in a dry powder formulation, microparticles may be formulated with large carrier particles that
aid flow from the DPI into the lung. Suitable carrier particles are known, and include lactose particles; they may have a mass median aerodynamic diameter of greater than 90 µm.

In the case of an aerosol-based formulation, a preferred composition is:

Compounds of the invention may be used in combination with other drugs that are used in the treatment/prevention/suppression or amelioration of the diseases or conditions for which present compounds are useful. Such other drugs may be administered, by a route and in an amount commonly used therefore, contemporaneously or sequentially with a compound of the invention. When a compound of the invention is used contemporaneously with one or more other drugs, a pharmaceutical composition containing such other drugs in addition to the compound of the invention is preferred. Accordingly, the pharmaceutical compositions of the invention include those that also contain one or more other active ingredients, in addition to a compound of the invention.

The agents of the invention may be administered in inhaled form. Aerosol generation can be carried out using, for example, pressure-driven jet atomizers or ultrasonic atomizers, preferably using propellant-driven metered aerosols or propellant-free administration of micronized active compounds from, for example, inhalation capsules or other "dry powder" delivery systems.

The active compounds may be dosed as described depending on the inhaler system used. In addition to the active compounds, the administration forms may additionally contain excipients, such as, for example, propellants
(e.g. Frigen in the case of metered aerosols), surface-active substances, emulsifiers, stabilizers, preservatives, flavorings, fillers (e.g. lactose in the case of powder inhalers) or, if appropriate, further active compounds.

For the purposes of inhalation, a large number of systems are available with which aerosols of optimum particle size can be generated and administered, using an inhalation technique which is appropriate for the patient. In addition to the use of adaptors (spacers, expanders) and pear-shaped containers (e.g. Nebulator®, Volumatic®), and automatic devices emitting a puffer spray (Autohaler®), for metered aerosols, in particular in the case of powder inhalers, a number of technical solutions are available (e.g. Diskhaler®, Rotadisk®, Turbohaler® or the inhalers for example as described EP-A-0505321).

Compounds formula (VIII) may be reacted with a benzaldehyde such as 4-cyanobenzaldehyde and a acetoacetate such as ethyl acetoacetate in the presence of an acid such as TMS-polyphosphate in a solvent such as THF at a temperature of from room temperature to reflux to give compounds of formula (VII), wherein \( R_3 \) is (Ci-\( C_6 \))alkyl and the other groups are as defined for compounds of formula (I). Compounds of formula (III) may be prepared from compounds of formula (VII) by reaction with an oxidizing agent such as urea hydrogen peroxide followed by in-situ treatment with hydrazine hydrate in IMS.

The skilled person may introduce, where appropriate, suitable variations to the conditions specifically described in the experimentals in order to adapt the synthetic routes to the provision of further compounds of the invention. Such variations may include, but are not limited to, the use of appropriate starting materials to generate different compounds, changes in the solvent and temperature of reactions, replacements of reagents with analogous chemicals, introduction or removal of protection/deprotection stages of functional groups sensitive to reaction conditions and reagents, as well as introduction or removal of specific synthetic steps oriented to further functionalisation of the
chemical scaffold.

Compounds used as starting materials or intermediates may be commercially available, their preparation may be specifically described in the literature or they may be prepared according to known methods.

The process described is particularly advantageous as it is susceptible of being properly modulated, through any proper known variant, so as to obtain any of the desired compounds. Such variants are comprised within the scope of the present invention.

From all of the above, it should be clear to the skilled person that any of the described groups may be present as such or in any properly protected form.

In particular, functional groups present in the Intermediates and Examples and which could generate unwanted side reaction and by-products, need to be properly protected before the alkylation, acylation, coupling or sulfonylation takes place. Likewise, subsequent deprotection of those same protected groups may follow upon completion of the said reactions.

In the present invention, unless otherwise indicated, the term "protecting group" designates a protective group adapted to preserve the function of the group it is bound to. Typically, protective groups are used to preserve amino, hydroxyl, or carboxyl functions. Appropriate protecting groups may thus include, for example, benzyl, benzyloxy carbonyl, t-butoxycarbonyl, alkyl or benzyl esters or the like, which are well known [see, for a general reference, T.W. Green; Protective Groups in Organic Synthesis (Wiley, N.Y. 1981)].

Likewise, selective protection and deprotection of any of the said groups, for instance including carbonyl, hydroxyl or amino groups, may be accomplished according to well known methods.

Optional salification of the compounds of formula (I) may be carried
out by properly converting any of the free acidic or amino groups into the corresponding pharmaceutically acceptable salts. In this case too, the operative conditions being employed for the optional salification of the compounds of the invention are all within the ordinary knowledge of the skilled person.

The diastereoisomers of compounds of formula (I), where available, may be obtained according to methods well known in the art, such as for example by preparative HPLC or by chromatographic purifications. A racemic mixture of compounds of formula (I) may as well be separated using preparative HPLC and a column with a chiral stationary phase, or resolved to yield individual enantiomers using methods well known in the art. Furthermore, chiral intermediates may be resolved and used to prepare chiral compounds of the invention.

From all of the above, it should be clear to the skilled person that the above process, comprehensive of any variant thereof for the preparation of suitable compounds of the invention, may be conveniently modified so that to adapt the reaction conditions to the specific needs, for instance by choosing appropriate condensing agents, solvents and protective groups, as the case may be.

Furthermore, compounds of formula (Id), i.e. compounds of formula (I) wherein $R_{14}$ is a group $-\text{COXR}_3$ and $R_1, R_2$ are hydrogen and $A$ is CH, may be prepared according to Scheme D here below reported:
Compounds of formula (XII) can be prepared from compounds of formula (VIII) using the methods described for the synthesis of compounds (Ia) in Scheme A and Scheme B. Compounds of formula (XI) may be prepared from compounds of formula (XII) by cleavage of the benzyl ester using an appropriate method such as reduction with a catalyst such as palladium on carbon in a solvent such as IMS under an atmosphere of hydrogen.

Compounds of formula (Id) may be prepared from compounds of formula (XI) by reaction with an alcohol or amine XHR₃ such as ammonia or 2-methoxyethanol in the presence of a coupling agent such as HATU in a solvent such as DMF in the presence of a base such as triethylamine at a temperature of from room temperature to 80°C.

The synthetic route shown in Scheme C would be of benefit in introducing XR₃ substituents at a late stage.
Alternatively, the acid intermediate (XI) may be prepared from compounds of formula (Ic) which are compounds of formula (I) wherein X is oxygen, R₃ is methyl, A, R₂ and R₁ are hydrogen, according to Scheme D below:

Scheme D

Treatment of a compound of formula (Ic) where XR₃ is OMe with a strong Lewis acid such as boron tribromide in a solvent such as DCM at a temperature of from -78°C to room temperature followed by quench with water or methanol can provide compounds of formula (XI).

It should be clear to the skilled person that other appropriate protecting group strategies may be contemplated and that the acid (XI) represents a versatile intermediate for further functionalisation as well as compounds of formula (Id).

By way of example, according to Scheme CI, by appropriate derivatization of a compound of formula (XI), as above defined, into a compound of formula (XVII) wherein R₁ is not hydrogen, corresponding compounds of formula (Ih) wherein R₁ is not hydrogen may be obtained.
Compounds of formula (XVII) may be obtained from compounds of formula (XI) using the methods described for the transformation of compounds of formula (la) to compounds of formula (lb) in Scheme E. Compounds of formula (Ih) may be prepared from compounds of formula (XVII) using the methods described for the conversion of compounds of formula (XI) to compounds of formula (Id) in Scheme C.

Compounds of formula (lb) as above defined may be prepared from compounds of formula (la) as above defined according to alternative methods described in Scheme E below.

Compounds of formula (la) may be transformed into compounds of formula (lb) wherein $R_1$ is an methylene-linked side-chain by reaction with an alkyl halide $R_1-X'$ in the presence of a base such as cesium carbonate in a solvent such as DMF at a temperature of from room temperature to 80°C.
Alternatively, the transformation may be achieved by Mitsunobu reaction with an alcohol R₁OH. Typical reagents employed are triphenyl phosphine and DIAD in a solvent such as THF.

Where R₁ = Aryl or heteroaryl a similar transformation may be achieved by the use of a Chan-Lam coupling reaction. Typical reaction conditions consist of the use of a boronic acid derivative, a copper catalyst such as copper acetate, a base such as triethylamine and a solvent such as pyridine at a temperature of from room temperature to reflux.

Compounds of formula (Ie), i.e. compounds of formula (I) wherein R₁₄ is a COXR₃ group and R₂ is a group -SO₂Me, may be prepared from compounds of formula (XVIII) according to Scheme F below:

Scheme F

![Scheme F diagram]

The transformation may be achieved by reaction of an aryl bromide with sodium methane sulfinite in the presence of a catalyst such as copper triflate, a ligand such as trans-cyclohexanediamine in a solvent such as DMSO at a temperature of up to 150°C.
Compounds of formula (If) or (Ig), i.e. compounds of formula (I) which incorporate a group (Ci - C_4)alkyleneNR_{9/7}R_{10/8} or a group (Ci - C_4)alkyleneN^+R_{11/15}R_{i_6}R_{i_3}R_{i_7} respectively as substituents, may be prepared according to Scheme G.

Compounds of formula (Ig) can be obtained directly by alkylation reaction of an appropriate tertiary amine R_{11/15}R_{i_6}R_{i_3}R_{i_7} and group -CH_2R represents the portion of a compound of formula (Ig) remaining out of its substitution by a group (Ci - C_4)alkyleneN^+R_{11/15}R_{i_6}R_{i_3}R_{i_7}.

Typical conditions could involve heating a tertiary amine in a solvent such as ethanol or THF at elevated temperatures of between 60°C and 150°C, using microwave irradiation.

Alternatively, the transformation of compounds of formula (XIX) to compounds of formula (Ig) may be achieved via the tertiary amine (If) where R_{9/7} and R_{10/8} ≠ H. Tertiary amine compounds of formula (Ig) may be prepared from compounds of formula (XIX) by reaction with a secondary amine R_{9/7}R_{10/8}NH. Typical reaction conditions include the use of a base such as cesium carbonate or potassium carbonate in a solvent such as DMF at RT. The conversion of compounds of formula (If), where R_{9/7} and R_{10/8} ≠ H, to
compounds of formula (Ig) can be obtained using methylating agents such as methyl bromide, methyl iodide or methyl benzenesulfonate. Typical reaction conditions consist of the use of a solvent such as MeCN or acetone at a temperature of between RT to 60°C under conventional or microwave heating.

Furthermore, primary and secondary amine compounds of formula (If) may also be prepared from compounds of formula (XIX) by reaction with ammonia or a suitable primary amine R<sub>9-7</sub>NH₂, respectively to give a primary amine or secondary amine.

Scheme H

Compounds of formula (Ij), i.e. compounds of formula (I) wherein R<sub>1</sub> is a group -CN, may be prepared according to Scheme H from compounds of formula (Ih), which are compounds of formula (I) wherein XR<sub>3</sub> is NH₂, by reaction with a dehydrating agent such as Burgess reagent in a solvent such as THF at a temperature of from room temperature to reflux.

General Experimental Details

Reactions were not carried out under an inert atmosphere unless specified. Where products were purified using an Isolute® SPE Si II cartridge, 'Isolute SPE Si cartridge' refers to a pre-packed polypropylene column containing unbonded activated silica with irregular particles with average size of 50 µm and nominal 60Å porosity. Where an Isolute® SCX-2 cartridge was used, 'Isolute® SCX-2 cartridge' refers to a pre-packed polypropylene column
containing a non end-capped propylsulphonic acid functionalised silica strong cation exchange sorbent. 'Isolute ® PE-AX cartridge' refers to a pre-packed polypropylene column containing a silica-based sorbent with a chemically bonded quaternary ammonium functional group. All solvents and commercial reagents were used as received.

\(^1\)H NMR spectra were recorded at ambient temperature using a Varian Unity Inova (400MHz) spectrometer with a triple resonance 5 mm probe. Chemical shifts are expressed in ppm relative to tetramethylsilane. The following abbreviations have been used: br = broad signal, s = singlet, d = doublet, dd = double doublet, t = triplet, td = triplet of doublets, q = quartet, m = multiplet.

Microwave experiments were carried out using a Biotage Initiator 60™ which uses a single-mode resonator and dynamic field tuning. Temperature from 40-250°C can be achieved, and pressures of up to 30 bar can be reached.

Compound names were generated using the Autonom 2000 feature in MDL ISIS™/Draw 2.5 SP2 software.

In the procedures that follow, some of the starting materials are identified through an "Intermediate" or "Example" number. This is provided merely for assistance to the skilled chemist. The starting material may not necessarily have been prepared from the batch referred to.

When reference is made to the use of a "similar" or "analogous" procedure, as will be appreciated by those skilled in the art, such a procedure may involve minor variations, for example reaction temperature, reagent/solvent amount, reaction time, work-up conditions or chromatographic purification conditions.

**Intermediate 1**

![Intermediate 1](image)

**4-(4-Cyanophenyl)-6-methyl-2-thioxo-1-(3-trifluoromethylphenyl)-1,2,3,4-tetrahydro-pyrimidine-5-carboxylic acid methyl ester**

Biological Assay

Compounds of this invention were tested for potency in a human neutrophil elastase (HNE) enzyme activity assay.

HNE Enzyme Assay

Assays were performed in 96-well plates in a total assay volume of 100 µL. The final concentration of elastase enzyme (human leukocyte elastase, Sigma E8140) was 0.0036 units/well or 0.00072 U/mL. The peptide substrate (MeOSuc-Ala-Ala-Pro-Val-AMC, Calbiochem #324740) was used at a final concentration of 100 µM. The final concentration of DMSO was 1% in the
assay buffer (0.05M Tris.HCl, 0.1M NaCl, 0.1M CaCl₂, 0.0005% brij-35, pH 7.5). The enzymatic reaction was started by addition of the enzyme and incubated at 25°C for 30 minutes. After incubation, the reaction was stopped by addition of soybean trypsin inhibitor (Sigma T9003) at a final concentration of 50 µg/well. Fluorescence was measured using a Molecular Devices fluorescence plate reader using 380 nm excitation and 460 nm emission wavelengths.

A dose response to each compound was performed and the effect of compound in each experiment was expressed as a percentage inhibition of the control enzyme fluorescence. Dose response curves were plotted and compound potency (IC$_{50}$) was determined. Compounds were tested in at least two separate experiments.

IC$_{50}$s for tested Examples, representative of the invention, are shown in the following table:
