(54) Titre : TECHNIQUE A GUTTA PERCHA INTEGRALE
(54) Title: INTEGRAL GUTTA PERCHA TECHNIQUE

(57) **Abrégé/Abstract:**

An integral, one-piece silanated particle impregnated gutta percha core/cone technique employs a thin layer of a luting agent, such as glass ionomer cement with a machined gutta percha core/cone, precisely matches the preparation, thereby reducing leakage and achieving a hermetic seal. The hermetic seal is further enhanced by a mono-block bond that occurs between the silanated particles in the gutta percha and the appropriate chemical sealant. Optional cryogenic treatment of the gutta percha material changes its molecular weight, making it stiffer and conducive to forming an integral, one piece core/cone, without the need for a separate carrier core to install the tapered gutta percha core/cone within the root canal. Additionally, the tapered body of the core/cone may be reticulated in a slightly three dimensional texturized framework to increase surface area and therefore increase retention. Optional line demarcation indicia are also placed on the core/cone. Additionally, the head of the core/cone can be gripped by a delivery vehicle clasp.

INTEGRAL GUTTA PERCHA TECHNIQUE

Field of Invention:

The present invention relates to Endodontics and, more specifically, the obturation (or the creation of a root canal seal by the use of a sealing material into the tight tapered apical end of a root canal) of the root canal space in a tooth.

Background:

Historically, there have been a number of ways to fill or obturate a root canal space. After a tooth has been thoroughly shaped and debrided of diseased nerve tissue, a filling of the space is required to prevent the ingress of contaminants from both the top section of the root canal (coronal) and the bottom portion (apical). The goal is a hermetic seal of the root canal system. The most common cause of failure of root canals is bacterial contamination either through microleakage or contamination during the process. The better the seal can be accomplished, the greater the long term prognosis of the tooth.

Initially silver points were used to fill the canal space, but due to leakage problems associated with their shape and the material itself, this technique was abandoned. This was replaced with the cold lateral filling by forcible condensation of gutta percha points.

Gutta percha is a naturally occurring trans isomer of rubber itself that can be modified into points. Gutta percha is typically formulated into a tapered conical shape (such as a .02 taper) to assume the tapered conical shape of the apical end of the root canal of a tooth. Because it is malleable, gutta percha at times has been inserted as an obturator. An obturator is a pointed instrument having a tapered distal end core and a cylindrical handle at the other end. The malleable gutta percha is wrapped around the tapered distal end core of the obturator instrument, and the handle is grasped manually. However, grasping the obturator manually often obstructs the view of the delivery process of the obturator into the root canal site.

Using a separate tapered carrier core for introducing gutta percha wrapped around it often results in uneven dislodging or stripping of the heated gutta percha from the obturator instrument.

5 Therefore, there is a need for an integral one piece gutta percha core/cone of the present invention, which acts as its own carrier, which can strongly bond to a thin layer of cement coating the inner walls of a root canal. This gutta percha core/cone of the present invention is used at
10 ambient room temperature, (not heated), and therefore is not subject to stripping or shrinkage.

Depending upon the commercial brand, gutta percha cones contain 18-23 % pure gutta percha. Waxes, resins, fillers, zinc oxide, and barium sulfate comprise the remainder of the
15 filling material (cones) known by the colloquial trade name of "gutta percha".

The cold lateral condensation filling technique employs a series of sequentially intertwined gutta percha cones placed in a sea of cement. The cement formula originally was
20 a zinc oxide eugenol cement. Although popular, this technique was subject to voids as a result of the lateral condensation filling and inaccuracies of adaptation to the root canal wall. It is very difficult with lateral condensation filling to achieve a three dimensional seal of
25 the root canal system.

The next change in the condensation filling process was the introduction of thermoplastic techniques that heated the gutta percha with hand instruments before insertion of the gutta percha into the apical end of the root canal. The
30 rationale behind thermoplastic gutta percha is that heated gutta percha flows and will more readily adapt to irregularities in the root canal system. Unfortunately, heated gutta percha flows only a few millimeters and shrinks upon cooling, thereby not filling the root canal space it was
35 intended to fill and seal. Consequently, the use of a luting agent is recommended with all thermoplastic techniques. While seemingly attractive, heated gutta percha has its

limitations. Shrinkage upon cooling and being technique sensitive are two of the limitations.

A further development in the obturation process was the introduction of alpha phase gutta percha inside the root canal on a carrier (plastic or metal). The combination of gutta percha on a carrier was referred to as an obturator. The success of this technique had the limitation of being dictated by the success of the preparation. If the taper of the preparation was not sufficient, the tooth structure could strip (denude) the gutta percha from the carrier, thereby reducing the success of the technique. A carrier that has a portion stripped of gutta percha increases the risk of bacterial contamination and therefore reduces the prognosis.

Recently, Endodontics has been witness to numerous heated gutta percha techniques that all have the common problem of shrinkage. Additionally, some of these techniques are technically sensitive making the use of thermoplastic techniques particularly challenging for the general practitioner.

There also was the concept of filling the entire root canal with a cement or paste, not utilizing gutta percha. This method had numerous problems such as lack of control of the material, and serious shrinkage that resulted in leakage and bacteria contamination. Revisement challenges were also a factor if the root canal procedure had to be re-treated.

Additionally, more recently, the concept of a single cone of gutta percha used with a large amount of cement has been advocated by Ultradent Incorporation with their ENDO-EZE® technique and its related Anatomic Endodontic Technology (AET)TM technique, using their ENDO-REZ® resin sealer.

However, the lack of synchronicity between the root canal preparation and the cone is a problem, as well as the cements, which do not adapt and bond well to the walls of the preparation or to the gutta percha itself. With the use of the Ultra Dent ENDO-EZE® preparation and the AETTM technique with the ENDO-REZ® resin sealer, there is inconsistency

between the root canal preparation and the gutta percha used to fill the root canal space. Therefore, the lack of a precise match between the preparation and the gutta percha itself results in either excess cement (that will shrink) or
5 the gutta percha cone can hang up in the coronal part of the canal and therefore, not reach the end of the root canal preparation intended to be sealed by the gutta percha. This can result in leakage and bacterial contamination thereby reducing the prognosis of the case.

10 However, Koch et al. and others, showed in 1993 that glass ionomer cement in its original formulation offered promise as a single cone cement to hold the gutta percha seal in place within the root canal. Other authors still expressed concern with the bond of the glass ionomer cement
15 to the gutta percha. In other words, while the bond of the glass ionomer to dentin was superior to other sealers, the bond to gutta percha was merely adequate. Another concern is the real probability that the large amount of cement in a single cone technique, as a thick layer of cement, will
20 shrink more than a thin layer of cement. This potential problem is the result of a lack of synchronicity between the root canal preparation and the gutta percha cone. As an example, one cannot place a .02 taper gutta percha cone into a .04 taper preparation and expect good results. The cone
25 must match the tapered and/or curved shape preparation of the root canal in as precise a manner as possible.

Furthermore, the restoration of endodontically treated teeth has been subject to a lack of synchronicity between the root canal preparation and a prefabricated post. The
30 consequence of this disparity is less than ideal retention of the post, as well as a weakening of the root when posts of greater dimension, or different shapes, are utilized, thereby compromising the long-term success of the restoration and the tooth.

35 An additional concern of the restoration of endodontically treated teeth is the lack of a proper coronal seal. The lack of a three dimensional seal (on top of the gutta percha in the root canal) can result in an ingress of

bacterial components. Bacterial contamination will result in failure of the root canal and remains a serious concern in modern endodontics.

Object of the Invention:

5 It is therefore the object of this invention to introduce the concept of synchronicity between the gutta percha core/cone and a machined preparation of a root canal wherein the gutta percha core/cone precisely matches the machined root canal preparation. Consequently, the matching
10 gutta percha core/cone in combination with a next generation glass ionomer cement reduces leakage and achieves a hermetic seal of the root canal. There are properties and designs unique to both the cement and gutta percha that distinguish this technique from any previous methodology. In particular,
15 the proposed invention includes gutta percha that has been modified by the inclusion of silanated glass and/or composite particles. These particles would ideally be in the sub micron range. The glass/composite impregnated gutta percha could also be surface treated with these same particles of
20 glass and/or composite and the gutta percha itself could be coated with a coupling agent, most likely but not exclusively an organosilane (e.g. 3-methoxy-propyl-trimethoxy-silane). The purpose of the inclusion of silanated particles would be to allow an intimate chemical bond to occur between the
25 silanated particles of the treated gutta percha and the appropriate chemical sealant. Additionally the gutta percha core/cone is delivered to the tooth (inserted) by use of a "TRANSPORTER"TM delivery vehicle facilitating its use in the endodontic procedure.

30 An additional object of this invention is to have a post system that precisely matches the endodontic preparation, thereby insuring the success of the post and the associated restoration.

 A further object of this invention is to have a system
35 (kit) that establishes a plug on top of the root canal, thereby insuring the seal of the said root canal.

Summary of the Invention:

In keeping with these objects and others which may become apparent, this invention takes a basic gutta percha cone and transforms it into a gutta percha core/cone, that functions as both the tapered filling cone and as its own carrier core. By optionally changing the molecular weight of a substance, such as gutta percha, one can change the properties of this material. The molecular weight of this gutta percha has been altered to produce a stiffer cone, which acts as its own structural core. Without the need for a separate interior carrier of plastic or metal, the gutta percha core/cone will occupy the entire space of the prepared root canal, with the exception of a microthin layer of luting agent between itself and the dentinal wall of the tooth. Additionally, the apical 16 mm of the core is preferably reticulated in a texture, such as a lattice (slightly three dimensional) framework to increase the surface area and thereby increase retention. Besides being a lattice, texturization may assume other surface interruption configurations, such as dimpling, stippling, irregular or parallel marking, etc. A further option for reticulation is the use of sand blasting, employing a granular substance, such as aluminum oxide.

A further option is to modify the gutta percha by the inclusion of silanated glass and/or composite particles. These particles would ideally be in the sub micron range. The glass/composite impregnated gutta percha could also be surface treated with these same particles of glass and/or composite and the gutta percha itself could be coated with a coupling agent, most likely but not exclusively an organosilane (e.g. 3-methoxy-propyl-trimethoxy-silane). The purpose of the inclusion of silanated particles would be to allow an intimate chemical bond to occur between the silanated particles of the treated gutta percha and the appropriate chemical sealant. This is achieved when the methacrylate groups of the silate coating form covalent bonds with various resins through a polymerization reaction. Ideally this sealer material would also form intimate chemical and/or micro-mechanical bonds to the dentinal

surface of the root canal. Thus, this bonded dentin-sealer gutta percha complex would create an impermeable mono-block effectively rendering the filled root canal hermetically sealed.

5 Another advantage of the treated particles would be to create a stiffer and more precisely shaped cone. This quality would allow greater ease of handling during the obturation (or filing) of a single core/cone. The filler particles would be composed of some combination of colloidal
10 silica, alumino-silicate clays and calcium fluoroaluminosilicate glasses that may or may not contain heavy metals. These particles could also include a colloidal complex of crushed silica-glass-resin composite. The particle size of all treated materials would ideally be in
15 the sub-micron range.

The sealers used could be in the form of glass ionomer cement (poly alkenoate acid cement) resin modified glass ionomer cement, or resin cement in the family of poly methyl methacrylates including, but not limited to, UDMA and BIS-
20 GMA. All of these materials are known to react with the silanated particles aforementioned to create a chemical complex between the sealer and the impregnated particles of the treated gutta percha resulting in the desired mono-block effect.

25 Optional line demarcation lengths, in millimeters, are also placed on the core/cone. These line demarcations may preferably alternate between thick and thin or vary numerically. As an example, thick lines may designate odd numbers and the thin lines may designate even lines, or vice
30 versa.

Additionally, the head of the core/cone has been shaped to accommodate the gripping portion of the TRANSPORTER™ delivery vehicle, such as disclosed in United States Patent No. 6,371,764 of Applicant Dennis Brave, dated April 16,
35 2002, for a dental instrument for placing gutta percha carried by an obturator into a root canal. In Brave '764, a clasp at the end of an elongated hand held handle of the obturator grasps the upper cylindrical handle of an obturator

core carrying gutta percha. In the present invention, the clasp grips the proximal end of the single piece core/cone of gutta percha for insertion into the root canal.

5 This will facilitate placement of the core/cone into the root canal.

Lastly, the gutta percha has been preferably optionally subject to cryogenic freezing treatment, thereby slightly increasing the surface area of the core/cone and increasing its retention to a glass ionomer cement. The molecular
10 structure of the gutta percha has also been altered by the cryogenic treatment to allow a more intimate contact between the glass ionomer cement and the gutta percha core. The cryogenic treatment additionally adds further rigidity to the gutta percha core/cone making it easier to place in curved
15 canals.

Adding to the system concept of this invention, the gutta percha core/cone is preferably independently packaged in a seal thereby assuring asepsis and reducing the potential for bacterial contamination.

20 Another concept of this single core/cone system is the option of having different cements to act as a luting agent. Siloxanes, such as polymethylvinyl siloxanes, as well as methacrylates, and other resin based cements will all work with this technique. The previously listed cements, epoxy
25 resins and glass ionomers will also meet the requirements of this technique. For example, synthetic or chemically modified naturally occurring resin sealers may be used. One preferable version of this invention uses a second generation glass ionomer cement that contains properties that ensure a
30 definitive bond to the dentin and an intimacy with the gutta percha core/cone. This particular cement additionally may contain a zinc component that adds to the antibacterial effect of this luting agent (acting as a sealer).

In summary, the present invention includes an endodontic
35 integral one-piece gutta percha core/cone, which, in combination with an appropriate luting agent properly seals, in a three dimensional manner, a root canal preparation space. Lateral canals can be more effectively filled with

sealers that exhibit little or no shrinkage, rather than thermoplastic obturation techniques that produce shrinkage upon cooling. Additionally there are sealers also available in endodontics, such as methyacrylates, that in fact expand
5 slightly rather than shrink, which can fill lateral canals of a root canal more successfully than thermoplastic gutta percha.

The gutta percha core/cone includes a handle portion adapted to be gripped by a hand or a delivery vehicle clasp.
10 A length determination section adjoins the handle portion with depth markings to indicate when the endodontic integral one piece core/cone is fully inserted into a root canal. The main body of the core/cone includes a conical section adjacent to the length determination section.

15 The tapered conical section is preferably reticulated to increase the surface area and is inserted into the root canal with a cement, such as a glass ionomer, which coats the surface area of the conical section. Reticulation may take any form of texturization, such as, for example, cross
20 hatching with intersecting longitudinally extending protrusions and recesses, or it may be in other forms, such as a plurality of individually protruding bumps, recessed dimples, or sand blasting with a substance such as aluminum oxide.

25 Optionally the gutta percha core/cone is cryogenically deep frozen, which increases bonding to the surface area of the tapered cone.

The endodontic integral one piece gutta percha core/cone is preferably packaged in a seal.

30 The core/cones may be provided in a set of core/cones with constant tip size and variable tapers, or with variable tip sizes and constant taper.

The post system that matches the core/cone is designed to fit a fully tapered .06 taper preparation with specific
35 sizing. The post includes an intra-radicular section and a "head" component that is coronal to the root canal orifice. This post may be fabricated from any of the common post

materials, such as stainless steel, titanium, titanium alloys, fiber components or ceramics.

Creation of a three dimensional coronal seal is a further object of this invention. This can be created through
5 the combination of a self-limiting drill (in multiple sizes) and an associated filling material, such as glass ionomer or a resin filler.

Brief Description of Drawings:

The present invention can best be understood in
10 connection with the accompanying drawings, in which:

Fig. 1 shows a front elevational view of the conically shaped gutta percha core/cone of the present invention, including the top, widest cylindrical handle portion, the next level of optional line markings and the lower tapered
15 reticulated intra canal portion;

Figs. 1A, 1B, 1C, 1D, 1E and 1F show a set of six gutta percha core/cones of the present invention, each individually marked according to optional ISO coordinated color markings on the top and side surfaces of the handle of each of the
20 respective gutta percha core/cones;

Fig. 2 shows a side view of the gutta percha core/cone of the present invention, which is a mirror image of the front view shown in Fig. 1, demonstrating the consistency in shape of the handle, length (depth) area, and the tapered
25 intracanal portion;

10 Fig. 8 is a simulated scanning electron microscope (SEM) crosssectional view of a microscopic portion of the present invention, showing a monolith effect of the synchronicity between the tooth (such as its dentin), the luting agent (such as glass ionomer cement) and the cryogenic treated gutta percha core/cone of the present invention.

15 Fig. 9 is a side crosssectional view of a tooth showing multiple lateral canals obturated with sealer following insertion of the core/cone.

Detailed Description of the Invention:

As shown in the drawing Figures 1-9, the integral, one
20 piece gutta percha core/cone 10 has three distinct structural components all produced from the same material, such as gutta percha.

The top (proximal end) of the core/cone 10 comprises the handle section 12. The handle 12 is machined to precisely fit
25 the core/cone TRANSPORTER™ delivery vehicle clasp 4 as shown in Fig 5B. This precise fit prevents the handle 12, and therefore the core/cone 10, from rotating or shifting when taken to and inserted into the root canal 2 of the prepared tooth 1.

30 Core/cone 10 is inserted within root canal 2 so as to seal the entire portion below its upper orifice 2a, above which includes upper chamber 2b of tooth 1, which is filled with tooth colored resin and related crown post work (not shown).

35 The handle 12 allows the TRANSPORTER™ delivery vehicle 4 to perform its functions, among which is to facilitate the placement of the one piece integral gutta percha core/cone 10

into a root canal 2 of a tooth 1 without danger of mis-insertion.

The optional but preferable length determination section 14 (with depth markings 14a) is another component of the gutta percha core/cone 10 and this segment of depth markings 14a has preferably measuring indicia, such as, for example, thick lines which denote odd lengths and thin lines which denote even numbered lengths, or vice versa. The lengths range from 16 mm at the first thick line 14 and extend to 27 mm at the last thick line 14a abutting the handle portion 12 of the core/cone 10. An additional 2 mm's may be gained by visually extending the indicia markings 14a proximally up until the beveled shoulder portion 16 of the cylindrical handle 12 at the proximal end of the conically shaped cone portion 18 of the core/cone 10 of the present invention.

A third segment of the gutta percha core/cone is the reticulated framework 20 extending from the most distal portion (distal apical tip 22 of core/cone 10), to the 16 mm line demarcation point 24. This reticulated framework 20 of varying optional texturizations 20a, is the portion of the core/cone 10 that is generally in the root canal 2 itself and its surface has been reticulated to increase the surface area, thereby increasing the retention of a luting agent sealer 8, such as preferably glass ionomer cement, to the core/cone 10.

In connection therewith, as shown in the simulated scanning electron microscope (SEM) depiction of Figure 8, the luting agent 8 is preferably applied in a microthin layer between the outside of the tapered portion of core/cone 10, and the dentinal material defining the tooth canal space. For example, the luting agent 8 is typically applied to fill the space, which is typically about from, but not limited to, about .01 mm to about 1.0 mm, with the exception of naturally occurring anatomical irregularities deviating from these dimensions, which are also filled by the luting agent 8.

Further adhesion is gained from the cryogenic treatment of the gutta percha core/cone 10.

The TRANSPORTER™ delivery vehicle 4 is a holding device that facilitates the precise insertion of the core/cone 10 into the root canal 2. In addition to contributing increased accuracy to the procedure, the TRANSPORTER™ delivery vehicle 4 helps the clinician insert the gutta percha core/cone 10 into the root canal 2 of all teeth without the fear of misdirection and consequential stripping of the luting agent sealer 8, such as cement, from the core/cone 10.

Another optional but preferable unique feature of this system is the cryogenic treatment of the gutta percha used to fabricate the core/cone 10. By a deep freezing process, the cryogenic treatment adds stiffness to the gutta percha and increases the surface area of the gutta percha core/cone 10, thereby resulting in a more intimate contact between the luting agent sealer 8 (such as glass ionomer cement) and the core/cone 10 itself. The result is increased retention.

Cryogenics changes the molecular structure of compounds to a martensite state rather than a retained austenite state. Therefore, coatings, such as luting agent sealers 8, have a greater affinity for martensite state rather than the austenite state. This results in a greater bond of the gutta percha core/cone 10 to the luting agent sealer 8.

The clinical application of this technique involves the creation of a machined fully tapered .03 to .08 preparation, preferably a .04 or .06 preparation in a root canal space 2. A machine preparation is achieved through the use of a rotary file sequence that prepares the canal in a predictable and consistent manner that produces a fully tapered preparation (.03 - .08mm). Examples of files that produce a fully tapered preparation are the PROFILE by Dentsply Tulsa Dental and the K-3 by SybronEndo. Following full instrumentation and debridement, the appropriate size gutta percha core/cone 10 is selected. As an example, if the final preparation is a machined, fully tapered .06 preparation, with an apical tip size of "20" (ISO), then a "20/.06" gutta percha core/cone is selected. Following core/cone selection, an appropriate luting agent sealer 8, such as cement, is mixed (glass

ionomer) and inserted into the root canal 2, creating a thin layer of luting agent sealer (cement) 8. The selected gutta percha core/cone 10 is then partially exposed in its sealed package 6 and is grabbed by the TRANSPORTER™ delivery vehicle 4. It is then fully removed by the TRANSPORTER™ delivery vehicle 4 from the sterile package maintaining asepsis. The chosen luting agent (root canal sealer 8), is then also placed on the gutta percha core/cone 10 itself, particularly over the reticulated area 20 of the core/cone 10 (apical 16 mm). It is recommended that gutta percha core/cone 10 be coated with the sealer 8 (cement) by wiping it gently through the mixed sealer 8.

The gutta percha core/cone 10 is now taken to the tooth and inserted into the prepared root canal 2 as far as the appropriate depth marking. After a few minutes, the lower tapered portion of the cemented gutta percha core/cone 10 is severed from the cylindrical handle 12 and length marking section 14, at the point of the orifice 2a of the canal 2 with a heated instrument, and subsequent light vertical condensation pressure is applied to the gutta percha core/cone 10.

Figures 6D and 6E show an alternate embodiment for a coronal seal that can be further assured by the placement of a cover 32 of bonded restorative material, such as the Applicant's "ENDO-KAP™" or "ENDO-SEAL™", which is any dental restorative material, such as glass ionomer or a bonded resin, placed into a prepared segment recess 30 created by the removal of gutta percha core/cone material from the coronal aspect on top of the filled root canal space occupied by the severed gutta percha core/cone 10. This will prevent leaking and bacterial contamination of the coronal aspect of the root canal filling and further prevent the need for retreatment, due to secondary bacterial invasion.

Furthermore, in those cases where a post/core is required for a satisfactory restoration of a further tooth 3 shown in Figure 6F, this invention includes a post system with post 40, as shown in Figure 6H, that matches the fully

tapered endodontic preparation of root canal 4 of tooth 3; so that synchronicity is maintained (for example, a .06 tapered post matches a .06 tapered endodontic preparation) between the preparation of root canal 4 and the post 40. There
5 remains in the root canal 4, below the post 40, a variable section 42 of gutta percha, which is located apical to the post 40, that insures an apical seal and prevents contamination from the apical portion of the tooth 3. The fully tapered post 40 is cemented with a luting agent such as
10 a glass ionomer or a resin-based sealer and the coronal section of the post 40 in Figure 6H is covered with a coronal buildup material 44. The resulting post/core restoration of post 40 and core buildup 44, as shown in Figure 6J, insures proper retention of the crown and also acts as an alternative
15 coronal seal to microleakage.

A further option is to have a planing instrument, in those cases with significant surface irregularities, such as the curvature in the root canal of Figure 6F, to refine the preparation, such as a .06 preparation, for example, in such
20 a manner as to accommodate the tapered inflexible post 40, such as shown in Figure 6G and thereby validate or verify the synchronicity between the preparation of the root canal 4 and the cemented post 40.

As shown in Figure 9, endodontic integral one piece
25 gutta percha core/cone 10, in combination with an appropriate luting agent 8, properly seals, in a three dimensional manner, a preparation space of root canal 6 of tooth 5, as well as lateral canals 7 extending therefrom. These lateral canals 7 are more effectively filled with sealers 8 that
30 exhibit little or no shrinkage, rather than thermoplastic obturation techniques that produce shrinkage upon cooling. These sealers 8, such as methylacrylates, expand slightly rather than shrink, and fill lateral canals 7 of root canal 6 more successfully than thermoplastic gutta percha.
35 Operation and Benefits of the Invention:

The gutta percha core/cone technique is an advance in Endodontics that facilitates the obturation of the root canal space for all clinicians. The synchronicity developed

between a machined fully tapered .03 to .08 preparation of a root canal 2, preferably a .04 or .06 preparation, and the precise match of the appropriate gutta percha core/cone 10 allows the dentist to achieve a precision fit in Endodontics, much like a precision fit in industry. As a result of this technique, clinicians can now not only fill a root canal 2 faster (thereby saving the patient time) but also they can fill it better in a true three dimensional sense. Because the fit is precise, the cement layer of luting agent sealer 8 between the gutta percha core/cone 10 and the tooth structure 1 (inside walls of the root canal 2) is very thin. A thin cement layer of luting agent sealer 8 is far less prone to shrinkage as compared to heated gutta percha, which shrinks significantly upon cooling. Additionally, when the interior of the root canal is properly conditioned with a chelating agent, such as EDTA, the dentinal tubules and lateral canals are opened sufficiently to allow the sealer (luting agent) to fill the spaces. The result is a better bond (retention) between the gutta percha and the dentinal wall, as well as more effective obturation of the lateral canals. Also, the modification of the gutta percha with silanated particles that bond to similar particles in the luting agent will result in less shrinkage. Consequently, the goal of a true hermetic seal is closer to being achieved with the gutta percha core/cone technique than any other prior art methods.

The unique design features of the gutta percha core/cone 10, along with the characteristics achieved by optionally having the core/cone 10 undergo cryogenic treatment, render multiple advantages to this technique.

The handle design of the core/cone 10 is unique and its design allows for ease of placement of the integral one piece gutta percha core/cone 10 into the prepared root canal 2 of a tooth 1. The handle 12 is also made of the same gutta percha material (which is identical to the rest of the core/cone 10) and therefore no separate solid core with a wrap of possibly precariously adhesable gutta percha is needed. This is important due to the viscosity of the sealer.

The texturized reticulated surface area 20, (such as, for example, a lattice framework or other dimpled texturization and the like) increases surface area and provides greater retention of the luting agent sealer 8, such as cement, to the core/cone 10. This unique feature enhances bonding between the luting agent sealer 8 (such as cement) and the core/cone 10 along with forming mechanical locks.

The preferably optional cryogenic treatment of the core/cone material (gutta percha) creates advantages previously unseen with gutta percha. By making the gutta percha stiffer, the cryogenic treatment allows the gutta percha core/cone 10 to work better with the viscosity of sealers (cements) associated with this technique. Stiffer gutta percha can be pre-curved into a one-piece integral gutta percha core/cone 10 without the need for a separate stiffer carrier core, and this feature will facilitate the "obturation" of more challenging root canal anatomy. Stiffer gutta percha is also easier for the clinician to handle, as well as to insert into the root canal space, thereby maintaining the integrity of the gutta percha core/cone 10.

Optional length markings 14 on the gutta percha core/cone 10 itself will facilitate accurate placement of the core/cone 10 into a canal 2, and will help ensure the success of the procedure. The packaging of each core/cone 10 in its own separate wrapper 6 will help reduce bacterial contamination during the process of obturation of a root canal space 2. As a result of this aseptic technique, the obturation process has a better prognosis.

It is further known that other embodiments may be made to the present invention, within the scope of the invention, as noted in the Claims.

WE CLAIM:

1. An endodontic integral once piece gutta percha core/cone capable of sealing a root canal preparation comprising a gutta percha conical member comprising gutta percha and at least one of silanated glass and/or composite particles.
2. The gutta percha core/cone as in claim 1 wherein said particles are selected from the group consisting of colloidal silica, alumino-silicate clays and calcium fluroaluminosilicate glasses.
3. The gutta percha core/cone as in claim 1 further comprising a sealer comprising a glass ionomer cement.
4. The gutta percha core/cone as in claim 3 wherein said glass ionomer cement is poly alkenoate acid glass ionomer cement.
5. The gutta percha core/cone as in claim 3 wherein said cement is resin modified.
6. The gutta percha core/cone as in claim 3 wherein said cement is a poly methyl methacrylate.
7. The gutta percha core/cone as in claim 6 wherein said methyl methacrylate is urethane dimethacrylate (UDMA).
8. The gutta percha core/cone as in claim 6 wherein said methyl methacrylate is bisglycidyl methacrylate (BIS-GMA).
9. A dental sealant composition comprising gutta percha and at least one of silanated glass and/or composite particles.
10. The dental sealant composition as Claim 9 wherein said particles are selected from the group consisting of colloidal silica, alumino-silicate clays and calcium fluroaluminosilicate glasses.
