(54) Title: DRY POWDER INHALERS FOR USE WITH PIEZOELECTRIC POLYMER-DRIVEN DELIVERY MEANS, AND ASSOCIATED BLISTER PACKAGE COMPRISING A PIEZOELECTRIC POLYMER MATERIAL

(57) Abstract: The present invention includes dry powder inhalers and associated multi-dose dry powder packages for holding inhalant formulated dry powder substances. The multi-dose package (100) comprises at least one thin piezoelectric polymer material layer (28) defining at least a portion of a plurality of spatially separated discrete elongate dry powder channels (101) having an associated length, width and height; and a metallic material (100m) attached to selected portions of the piezoelectric polymer material (28) including each of the regions corresponding to the elongate dry powder channels (101) to, in operation, define active energy releasing vibratory channels. In operation, the elongate channels can be selectively individually activated to vibrate upon exposure to an electrical input. The dry powder inhaler (10) includes an elongate body (10b) having opposing first and second outer primary surfaces (11, 12) with a cavity (10c) therebetween and a multi-dose sealed blister package (100) located in the said cavity (10c). The inhaler (10) also includes a cover member (15) that is pivotally attached to the elongate body (10b).

WO 2003/095010 A3

DRY POWDER INHALER WITH A MULTI-DOSE DISK AND ROTATING COVER

Field of the Invention

The present invention relates to the delivery of dry powder substances, such as dose-regulated pharmaceutical products, as inhalant aerosols.

Background of the Invention

Dry powder inhalers (DPI's) represent a promising alternative to pressurized pMDI (pressurized metered dose inhaler) devices for delivering drug aerosols without using CFC propellants. *See generally*, Crowder et al., *2001: an Odyssey in Inhaler Formulation and Design*, Pharmaceutical Technology, pp. 99-113, July 2001; and Peart et al., *New Developments in Dry Powder Inhaler Technology*, American Pharmaceutical Review, Vol. 4, n.3, pp.37-45 (2001). Typically, the DPIs are configured to deliver a powdered drug or drug mixture that include an excipient and/or other ingredients. Conventionally, many DPIs have operated passively, relying on the inspiratory effort of the patient to dispense the drug provided by the powder. Unfortunately, this passive operation can lead to poor dosing uniformity since inspiratory capabilities can vary from patient to patient (and sometimes even use-to-use by the same patient, particularly if the patient is undergoing an asthmatic attack or respiratory-type ailment which tends to close the airway).

Generally described, known single and multiple dose dry powder DPI devices use: (a) individual pre-measured doses, such as capsules containing the drug, which can be inserted into the device prior to dispensing; or (b) bulk powder reservoirs which are configured to administer successive quantities of the drug to the patient via a dispensing chamber which dispenses the proper dose. *See generally* Prime et al., *Review of Dry Powder Inhalers*, 26 Adv. Drug Delivery Rev., pp. 51-58 (1997); and Hickey et al., *A new millennium for inhaler technology*, 21 Pharm. Tech., n. 6, pp. 116-125 (1997).

In operation, DPI devices desire to administer a uniform aerosol dispersion amount in a desired physical form (such as a particulate size) of the dry powder into a patient's airway and direct it to a desired deposit site. If the patient is unable to provide sufficient respiratory effort, the extent of drug penetration, especially to the lower portion of the airway, may be impeded. This may result in premature deposit of the powder in the patient's mouth or throat.

A number of obstacles can undesirably impact the performance of the DPI. For example, the small size of the inhalable particles in the dry powder drug mixture can subject them to forces of agglomeration and/or cohesion (*i.e.*, certain types of dry powders are susceptible to agglomeration, which is typically caused by particles of the drug adhering together), which can result in poor flow and non-uniform dispersion. In addition, as noted above, many dry powder formulations employ larger excipient particles to promote flow properties of the drug. However, separation of the drug from the excipient, as well as the presence of agglomeration, can require additional inspiratory effort, which, again, can impact the stable dispersion of the powder within the air stream of the patient. Unstable dispersions may inhibit the drug from reaching its preferred deposit/destination site and can prematurely deposit undue amounts of the drug elsewhere.

Further, many dry powder inhalers can retain a significant amount of the drug within the device, which can be especially problematic over time. Typically, this problem requires that the device be disassembled and cleansed to assure that it is in proper working order. In addition, the hygroscopic nature of many of these dry powder drugs may also require that the device be cleansed (and dried) at periodic intervals.

Some inhalation devices have attempted to resolve problems attendant with conventional passive inhalers. For example, U.S. Patent No. 5,655,523 proposes a dry powder inhalation device which has a deagglomeration/aerosolization plunger rod or biased hammer and solenoid, and U.S. Patent No. 3,948,264 proposes the use of battery-powdered solenoid buzzer to vibrate the capsule to effectuate the release of the powder contained therein. These devices propose to facilitate the release of the dry powder by the use of energy input independent of patient respiratory effort. U.S. Patent No. 6,029,663 to Eisele et al. proposes a dry powder inhaler delivery system with a rotatable carrier disk having a blister shell sealed by a shear layer that uses an actuator that tears away the shear layer to release the powder drug contents. The device also includes a hanging mouthpiece cover that is attached to a bottom portion of the inhaler. U.S. Patent No. 5,533,502 to Piper proposes a powder inhaler using patient inspiratory efforts for generating a respirable aerosol and also includes a rotatable cartridge holding the depressed wells or blisters defining the medicament holding receptacles. A spring-loaded carriage compresses the blister against conduits with sharp edges that puncture the blister to release the medication that is then entrained in air drawn in from the air inlet conduit so that aerosolized medication is emitted from the aerosol outlet conduit.

More recently, Hickey et al. in international PCT patent publication WO 01/68169A1 have proposed a DPI system to actively facilitate the dispersion and release of dry powder drug formulations during inhalation using piezoelectric polymer film elements which may promote or increase the quantity of fine particle fraction particles dispersed or emitted from the device over conventional DPI systems.

Notwithstanding the above, there remains a need to provide easily used, cost effective, and reliable dry powder inhalers.

Summary of the Invention

Embodiments of the present invention provide improved dry powder inhaler configuration. The dry powder inhalers may be particularly suitable for use with active piezoelectric polymer-driven dispersion or delivery means. Embodiments of

the present invention are directed to dry powder inhaler configurations and associated receptacle or blister packages as well as methods for dispensing dry powder substances and/or methods for fabricating blister packages.

5 In certain embodiments, the dry powder inhaler can be pre-packaged with an integrated predetermined quantity of individually dispensable doses that is disposable after a desired dispensing period, such as 30, 60, or 90 days. This can limit the amount of patient or user interchange with the dry powder inhaler, thereby removing the requirement that the DPI be disassembled to insert additional doses into the unit (and may also promote a more hygienic product). In other embodiments, the DPI can
10 be configured to allow replaceable dry powder packages to be inserted/removed from the device at desired intervals.

In particular embodiments, whether the inhaler is disposable at each refill interval or refillable and reusable, the dry powder package therein can include a thin layer of piezoelectric polymer material that is in communication with each of a
15 plurality of selectively excitable receptacle regions. In operation, the piezoelectric polymer material layer is rapidly flexed back and forth to deform a selected receptacle(s) region, thereby actively facilitating the dispersal of the dry powder drug into the inhalation delivery path.

The active piezoelectric regions can be formed as an elongated resonant
20 chamber to cause the dry powder substance to contact the floor and/or ceiling of the resonant chamber repeatedly. This can increase the transfer of energy from the actively flexing piezoelectric polymer resonant chamber to the dry powder substance, promoting longer contact times therewith as the dry powder substance travels the length of the resonant chamber and exits the patient inhalation port.

25 The increased active dispersal can promote resonance of the dry powder substance and allow improved blends, such as increased concentrations and/or reduced total quantities of substances relative excipient, over conventional dry powder pharmaceutical substances.

Certain embodiments of the present invention are directed to multi-dose dry
30 powder packages for holding inhalant formulated dry powder substances. The packages comprise: (a) a platform body comprising a plurality of sealed blisters thereon and at least one thin piezoelectric polymer material layer forming at least a portion of each of the sealed blisters, wherein the sealed blisters comprise a respective

at least one of a plurality of spatially separated discrete elongate dry powder channels having an associated length, width and height; and (b) a conductive material attached to selected portions of the piezoelectric polymer material to, in operation, define active energy-releasing vibratory channels, and wherein, in operation, the elongate
5 channels can be selectively activated to vibrate upon exposure to an electrical input.

Other embodiments of the invention are directed to dry powder inhalers. The inhalers include: (a) an elongate body having opposing first and second outer primary surfaces with a cavity therebetween and having opposing top and bottom end portions; (b) a multi-dose sealed blister package holding a plurality of discrete metered
10 doses of a dry powder inhalable product located in the cavity of the elongate body; (c) an inhalation port formed in the bottom end portion of the elongate body, the inhalation port configured to be in fluid communication with at least one of the discrete metered doses during use; and (d) a cover member that is pivotably attached to the elongate body so that it remains attached to the body during normal operational
15 periods of use and moves to a first closed position to overlie the inhalation port at the bottom end portion of the body during periods of non-use and moves to a second open position away from the inhalation port during periods of use to allow a user to access the inhalation port.

The cover member may have a length that is greater than a major portion of
20 the length of the elongated body and a width is less than the width of the elongate body. In certain embodiments, the cover member has two opposing first and second end portions, the first end portion being pivotably attached to the upper portion of the elongated body with the cover having a major portion with a substantially planar profile and a downwardly extending arcuately shaped second end portion.

25 Still other embodiments of the present invention are directed to methods for fabricating a multi-dose disposable dry powder blister package. The method includes: (a) providing a piezoelectric polymer material; (b) concurrently forming a plurality of elongated projections having a width and an associated length into the piezoelectric polymer material; and (c) applying a metallic material to selected regions of at least
30 one primary surface of the piezoelectric polymer material so as to cover at least a portion of each of the plurality of projections.

Another embodiment of the invention is directed to methods of administering an inhalable dry powder product to a subject. The method includes: (a) oscillating a

piezoelectric polymer material forming at least a portion of a sealed encased elongated channel and having opposing first and second end portions at a selected frequency or frequency range; (b) disrupting the integrity of the seal associated with the elongated channel at a second end portion; (c) directing a dry powder product to flow through the elongated channel to exit at the second end portion so that a major portion of the dry powder substance repeatedly contacts the oscillating piezoelectric material at a plurality of locations along the elongated channel; (f) imparting energy to the dry powder product based on the oscillating and directing steps to cause the dry powder product to vibrate to generate an inhalable aerosol; and (g) releasing the inhalable aerosol to a subject upon inhalation.

Still other embodiments are directed toward methods of administering an inhalable dry powder products to a subject. The methods include: (a) providing an inhaler with a multiple dose blister package comprising piezoelectric polymer material that is associated with a plurality of discrete sealed blisters holding respective dry powder doses; (b) priming a selected portion of the package to vibrate the dry powder in at least one selected sealed blister proximate in time to an intended inhalation delivery thereof; then (c) introducing an opening in the at least one selected blister; (d) vibrating the at least one selected blister by applying an input signal to the piezoelectric polymer material proximate the selected blister; and (e) releasing the inhalable dry powder to a subject upon inhalation.

According to an aspect of the present invention there is provided a dry powder inhaler, comprising:

an elongate body defining a substantially enclosed cavity and having opposing upper and lower primary surfaces, the elongate body having a width dimension and a length dimension, the length dimension being greater than the width dimension, the length dimension extending between opposing first and second ends of the elongate body, the width dimension extending normal to the length dimension between opposing sides of the elongate body;

a multi-dose disk located in the cavity of the elongate body, the disk holding a plurality of doses of an inhalable dry powder;

a mouthpiece with an inhalation port residing at the first end of the elongate body between the upper and lower primary surfaces so as to be externally accessible by a user while the elongate body remains closed, the inhalation port configured to be in fluid communication with at least one of the doses of dry powder during use; and

a cover member having an upper surface that is attached to the elongate body to pivot about an axis of rotation that is substantially normal to the upper primary surface, wherein the axis of rotation is longitudinally offset from a center of the length dimension of the elongate body to reside closer to the second end of the elongate body while being substantially centered in the width dimension, wherein the cover member rotates between a closed position to overlies the mouthpiece during periods of non-use and an open position away from the mouthpiece during periods of use to allow a user to access the inhalation port while the elongate body remains closed, and wherein the cover member rotates from the closed position to the open position about the axis of rotation so that the upper surface of the cover member remains substantially parallel to the upper primary surface of the elongate body.

According to another aspect of the present invention there is provided a dry powder inhaler, comprising:

an inhaler housing body defining a substantially enclosed cavity;

a multi-dose disk located in the cavity of the housing body, the disk holding a plurality of circumferentially spaced apart doses of an inhalable dry powder;

a mouthpiece with an inhalation port supported by the housing body so as to be externally accessible by a user while the housing body remains closed, the inhalation port configured to be in fluid communication with at least one of the doses of dry powder during use; and

a cover member that is attached to an upper primary surface of the housing body to be able to pivot about an axis of rotation that is substantially normal to the upper primary surface of the housing body, wherein the cover member has a planar upper surface that overlies the upper primary surface of the housing body when closed, wherein the axis of rotation is substantially centered in a width dimension of the housing body, and wherein the cover member rotates between a closed position to overlies the mouthpiece during periods of non-use and an open position away from the mouthpiece during periods of use to allow a user to access the inhalation port while the housing body remains closed,

wherein the housing body is an elongate body and the mouthpiece resides on one end of the elongate body between upper and lower primary surfaces, and wherein the axis of rotation is longitudinally offset to reside closer to an end of the housing body without the mouthpiece, and wherein the cover member rotates from the closed position to the open position about the axis of rotation so that the upper surface of the cover member remains substantially parallel to the upper primary surface of the elongate body.

According to another aspect of the present invention there is provided a dry powder inhaler, comprising:

an elongate body having opposing first and second outer primary surfaces with a substantially enclosed cavity therebetween and having opposing top and bottom end portions;

a multi-dose sealed blister package holding a plurality of discrete metered doses of a dry powder inhalable product located in the cavity of the elongate body;

an inhalation port extending through a mouthpiece in the bottom end portion of the elongate body so as to be externally accessible by a user while the elongate body remains closed, the inhalation port configured to be in fluid communication with at least one of the discrete metered doses during use; and

a cover member that is pivotally attached to the elongate body and rotates between a first closed position to overlie the inhalation port and mouthpiece at the bottom end portion of the body during periods of non-use and a second open position away from the inhalation port during periods of use to expose the inhalation port and mouthpiece and allow a user to access the inhalation port on the bottom end of the elongate body while the elongate body remains closed, wherein the cover member has a length and width sufficient to extend from the bottom end to proximate the top end portion of the inhaler body when the cover is in the closed position, and wherein the cover has a first end portion with an arcuate profile that extends downwardly substantially conformally over the inhaler bottom end when in the closed position.

These and other objects and/or aspects of the present invention are explained in detail in the specification set forth below.

Description of Embodiments of the Invention

The present invention will now be described more fully hereinafter with reference to the accompanying figures, in which embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Like numbers refer to like elements throughout. In the figures, certain layers, components or features may be exaggerated for clarity, and broken lines illustrate optional features or operations unless specified otherwise. In addition, the sequence of operations (or steps) is not limited to the order presented in the claims unless specifically indicated otherwise. Where used, the terms “attached”, “connected”, “contacting”, and the like, can mean either directly or indirectly, unless stated otherwise.

In the description of the present invention that follows, certain terms are employed to refer to the positional relationship of certain structures relative to other structures. As used herein, the term “front” or “forward” and derivatives thereof refer to the general or primary direction that the dry powder travels as it is dispensed to a patient from a dry powder inhaler; this term is intended to be synonymous with the term “downstream,” which is often used in manufacturing or material flow environments to indicate that certain material traveling or being acted upon is farther

along in that process than other material. Conversely, the terms “rearward” and “upstream” and derivatives thereof refer to the directions opposite, respectively, the forward and downstream directions. The term “blister” means a dry powder receptacle that can hold a (typically meted) quantity of a dry powder product. The
5 blister may be configured with an elongated channel or cavity as will be described further below, or configured in other suitable geometries. In operation, the blisters are opened (slit, punctured or otherwise parted) before the dry powder dose is released by the inhaler in the aerosolized inhalant form.

The devices and methods of the present invention may be particularly suitable
10 to dispense dry powder substances to *in vivo* subjects, including animal and, typically, human subjects. The dry powder substance may include one or more active pharmaceutical constituents as well as biocompatible additives that form the desired formulation or blend. As used herein, the term “dry powder” is used interchangeably with “dry powder formulation” and means the dry powder can comprise one or a
15 plurality of constituents or ingredients with one or a plurality of (average) particulate size ranges. The term “low-density” dry powder means dry powders having a density of about 0.8 g/cm^3 or less. In particular embodiments, the low-density powder may have a density of about 0.5 g/cm^3 or less. The dry powder may be a dry powder with cohesive or agglomeration tendencies.

20 In any event, individual dispensable quantities of dry powder formulations can be a single ingredient or a plurality of ingredients, whether active or inactive. The inactive ingredients can include additives added to enhance flowability or to facilitate aerosolization delivery to the desired systemic target. The dry powder drug formulations can include active particulate sizes that vary. The device may be
25 particularly suitable for dry powder formulations having particulates which are in the range of between about $0.5\text{-}50\mu\text{m}$, typically in the range of between about $0.5\mu\text{m}$ - $20.0\mu\text{m}$, and more typically in the range of between about $0.5\mu\text{m}$ - $8.0\mu\text{m}$. The dry powder formulation can also include flow-enhancing ingredients, which typically have particulate sizes that may be larger than the active ingredient particulate sizes.
30 In certain embodiments, the flow-enhancing ingredients can include excipients having particulate sizes on the order of about $50\text{-}100 \mu\text{m}$. Examples of excipients include lactose and trehalose. Other types of excipients can also be employed, such as, but

not limited to, sugars which are approved by the United States Food and Drug Administration ("FDA") as cryoprotectants (e.g., mannitol) or as solubility enhancers (e.g., cyclodextrine) or other generally recognized as safe ("GRAS") excipients.

Examples of diseases, conditions or disorders that may be treated with the inventive devices and methods include, but are not limited to, asthma, COPD (chronic obstructive pulmonary disease), viral or bacterial infections, influenza, allergies, and other respiratory ailments as well as diabetes and other related insulin resistance disorders. The dry powder inhalant administration may be used to deliver locally acting agents such as antimicrobials, protease inhibitors, and nucleic acids/oligonucleotides as well as systemic agents such as peptides like leuprolide and proteins such as insulin. For example, inhaler-based delivery of antimicrobial agents such as antitubercular compounds, proteins such as insulin for diabetes therapy or other insulin-resistance related disorders, peptides such as leuprolide acetate for treatment of prostate cancer and/or endometriosis and nucleic acids or oligonucleotides for cystic fibrosis gene therapy may be performed. *See e.g. Wolff et al., Generation of Aerosolized Drugs, J. Aerosol. Med. Pp. 89-106 (1994).* See also U.S. Patent Application Publication No. 20010053761, entitlement *Method for Administering ASPB28-Human Insulin* and U.S. Patent Application Publication No. 20010007853, entitled *Method for Administering Monomeric Insulin Analogs*.

Typical dose amounts of the unitized dry powder mixture dispersed in the inhaler will vary depending on the patient size, the systemic target, and the particular drug. Conventional exemplary dry powder dose amount for an average adult is about 10-30 mg and for an average adolescent pediatric subject is from about 5-10 mg. Exemplary dry powder drugs include, but are not limited to albuterol, fluticasone, beclamethasone, cromolyn, terbutaline, fenoterol, β -agonists, salmeterol, formoterol, and glucocorticoids. In certain embodiments, the administered bolus or dose can be formulated with an increase in concentration (an increased percentage of active constituents) over conventional blends. Further, the dry powder formulations may be configured as a smaller administerable dose compared to the conventional 10-25 mg doses. For example, each administerable dry powder dose may be on the order of less than about 60-70% of that of conventional doses. In certain particular embodiments, using the active dispersal systems provided by certain embodiments of the DPI

configurations of the instant invention, the adult dose may be reduced to under about 15 mg, such as between about 10 μ g-10mg, and more typically between about 50 μ g-10mg. The active constituent(s) concentration may be between about 5-10%. In other embodiments, active constituent concentrations can be in the range of between
5 about 10-20%, 20-25%, or even larger. In particular embodiments, such as for nasal inhalation, target dose amounts may be between about 12-100 μ g.

In certain particular embodiments, during dose dispensing, the dry powder in a particular dose receptacle may be formulated as only an active pharmaceutical constituent(s), substantially without additives (such as excipients). As used herein,
10 “substantially without additives” means that the dry powder is in a substantially pure active formulation with only minimal amounts of other non-biopharmacological active ingredients. The term “minimal amounts” means that the non-active ingredients may be present, but are present in greatly reduced amounts, relative to the active ingredient(s), such that they comprise less than about 10%, and preferably less
15 than about 5%, of the dispensed dry powder formulation, and, in certain embodiments, the non-active ingredients are present in only trace amounts.

In certain embodiments, the active elements are integral to/included as part of the disposable drug package, unlike many conventional active dispersion systems, cleansing of the active mechanism portion of the inhaler may not be required.

Referring to **Figure 1**, one embodiment of a dry powder inhaler **10** is shown. The inhaler **10** can be configured as an elongated body **10b** defining an internal cavity **10c** (**Figure 8**). The inhaler **10** includes a top primary surface **11** and an opposing bottom primary surface **12** (**Figure 6**). A window **17** may be formed into the body of the inhaler **10** to allow a user to have visual contact with an enclosed multi-dose dry
25 powder package **100**. The window **17** may include a transparent or translucent member or an aperture. The former may reduce environmental contamination during use.

As illustrated, the inhaler **10** can include a pivotably attached cover member **15** that overlies a major portion of the top surface **11**. The cover member **15** can pivot
30 about any desired portion of the device. As shown, the cover member **15** includes an end portion with an aperture **15a** that may correspond to the size of a window **17**. The cover member **15** attaches to the top portion of the elongated body **10b** and pivots

03-08-2004

about an axis that is normal to the window 17. Figure 1 illustrates the cover member 15 in a closed position where it blends with profile contour of the perimeter of the elongated body 10b. The cover member 15 may be formed of an elastomeric material that has increased flexibility relative to the elongated body.

5 As shown in Figures 3 and 5, the elongated body 10b can have a thin profile when viewed from the side with planar top and bottom surfaces 11, 12. As used herein, the term "thin" means less than about 1.5 inches (3.81 cm) thick, and more preferably is about 1 inch (2.54 cm) or less in width (the width "W" being the distance between the top and bottom surfaces 11, 12, as shown in Figure 5).

10 The elongated body 10b can be configured to be pocket-sized (fitting into standard pockets on male and/or female clothing). By using substantially planar primary surfaces 11, 12, and/or a thin profile, the device 10 may be less obtrusively worn (less conspicuous) and/or more conformal to the body and less intrusive in clothing pockets. In certain embodiments, the length of the elongated body is
15 between about 2-5 inches (5.08 – 12.7 cm), typically under about 4.25 inches (10.795 cm), with the width being about 2-4 (5.08 – 10.16 cm) inches, typically about 2.5 inches (6.35 cm).

Figure 1 also illustrates that the multi-dose dry powder drug package 100 can include a plurality of circumferentially spaced-apart elongated channels 101, each
20 sealed with a quantity of dry powder product disposed therein. Each of the elongated channels 101 can be numbered with an alphanumeric indicia 101i to indicate the present dose located in the dispensing channel. Figure 7 is an enlarged view of the window and underlying portion of the package 100. In other embodiments, visible indicia and/or audible alerts can be used to warn a user that he/she is approaching the
25 last of the filled inhalant doses. For example, color enhanced markings can be used for the last few (such as the last 5 doses) the color enhanced may change from darker (orange to salmon or red) or to completely different colors as the last dose or last few doses approach. Alternatively (or additionally), the multi-dose disposable package
100 may be configured with audible alert features that activate a digital signal
30 processor or micro-controller (not shown) housed in the elongated body 10 to generate a stored audible warning (such as "warning, refill needed, only five doses remain) when a desired number of doses have been administered.

03-08-2004

Turning to Figures 2 and 3, as shown, the cover member 15 can be configured so that a major length is relatively thin and planar and overlies a major

portion of the top surface **11** of the body when the cover member **15** is in a closed position. The outer end portion **15a** of the cover member **15** that covers the mouthpiece **20** can be arcuately configured so as to snugly abut or frictionally align and engage the bottom end portion of the elongated body **10b** when closed. That is, the curvature conforms to the curvature of the bottom or side edge of the elongated body **10e** adjacent the mouthpiece **20**.

Figure 4 illustrates that the lower portion **15a** of the cover member **15** moves away from the bottom portion **10e** of the elongated body **10b** to reveal the inhalation port **18** of the mouthpiece **20**. This allows a user access to the mouthpiece **20** and associated inhalation port **18**. Because the cover member **15** is retained on the device during normal operation (whether open or closed) and positioned in a non-interfering location, it is less likely to be lost or removed from the device. As shown, the cover member **15** may pivot to reside about the opposing end portion **10oe** and overhang the elongated body **10b**. As the cover member **15** pivots or rotates about the front surface **11**, it exposes an activation button **25** that, when depressed, initiates the active dispensing of the dry powder substance(s) located in the inhalation output or dispensing region of the device **10**. As with conventional inhalant devices, the active inhalation may involve puncturing or disrupting a thin cover material (that may be an elastomeric or polymer sealant cover or even another layer of piezoelectric polymer) disposed over the powder. In any event, the cover member **15** may be configured with an upwardly extending projection region or mound **15p** that is configured to overlie the activation button **25** when closed. The mound **15p** may be configured to define a sufficient air pocket to inhibit inadvertent activation of the button **25**. The mound **15p** may be formed of the same flexible elastomeric material as the remainder of the cover member **15**, or may be formed of a stiffer material for additional protection.

In certain embodiments, the elongated body **10b** may include a recess positioned about the mouthpiece **20** that can be sized to matably receive the cover member **15** therein so that the cover member **15** pops into or nests in and/or locks into the closed position (not shown). Similarly, the pivotal attachment of the cover member **15** can be configured with a ratcheting wheel or gear that biases the cover member **15** into a desired closed and/or open position.

Although shown as positioned to overlie the top surface **11** of the elongated body **10b**, the cover member **15** may be configured to extend from the bottom surface **12** upwardly to cover the mouthpiece **20**. Similarly, the pivotal attachment can be laterally offset instead of longitudinally offset as shown.

5 **Figure 6** illustrates that the bottom surface **12** of the elongated body **10b** can include an indexing mechanism **30** that allows a user to advance the multi-dose package **100** to the next dry powder dose. The indexing mechanism **30** or a similar knob can include alignment indicia **30i** (shown herein as an arrowhead) that can be aligned with alignment indicia **10i** on the housing body **10b** to allow the elongated
10 body **10b** to be disassembled and more easily reassembled with a replacement disposable multidose package **100**. The indexing mechanism **30** can reside in other locations and configured in other electrical and/or mechanical configurations.

In certain embodiments, the mouthpiece **20** can be removed by disengaging and/or pulling it from its adjacent portion of the inhaler **10** without requiring further
15 disassembly of other components. This can allow the mouthpiece **20** to be cleaned as desired. Typically, the mouthpiece **20** is snapped into and held in position by a friction fit joint. Of course, other connection components and configurations may also be used as is known to those of skill in the art.

Figure 8 illustrates that the elongated body **10b** can be configured as two
20 primary matable first and second housing members **11b**, **12b** that allow the disposable package **100** to be replaced as needed. In other embodiments, the entire elongated body **10b** and contents are disposable after depletion of the dispensable doses (whether a 30, 60, 90 or other day supply). The contents typically include the control system, a microchip such as a digital signal processor (not shown), power source
25 (battery)(not shown), and the package **100**.

Figure 8 illustrates the package **100** in the cavity **10c** with the elongated channels **101** formed of the piezoelectric polymer material oriented with the projection curving up (projecting upwardly). In this embodiment, the piezoelectric material can define the ceiling and the opposing sidewalls. However, in certain
30 embodiments, as shown in **Figures 9, 10A, and 10B** the package **100** has a reversed orientation so that the elongated channels **101** have the projection curving down (projecting downwardly). In the latter configuration, the piezoelectric material can define the floor and sidewalls of the channel **101**. As will be described further below,

the piezoelectric polymer material can be deposited, coated, sprayed, inked, foiled, or otherwise layered with a metallic conductive material at selected regions of the package **100** and along at least a portion of each of the elongated channels **101** to define a vibrating or flexing active region when activated by an excitation voltage.

5 **Figure 9** illustrates that the elongated channels may include a sealant layer **120** that seals the elongated channels **101**. The sealant layer **120** may be a thin polymer film material, a foil layer, and, in certain embodiments, may be another layer of piezoelectric polymer film that is also coated or layered with metal to become activated during dispensing. In any event, the sealant layer **120** may be a ceiling with
10 an end portion **120s** that is scored, notched or otherwise formed so that it is preferentially predisposed to part, puncture or split upon exposure to a blunt pressure (such as based on actual contact with a dose release or puncture device or an elevated pressure). In certain embodiments, the end portion **120s** closest to the mouth of the user is notched or scored to increase the travel distance of the dry powder along the
15 length of the elongated channel **101**, which can increase the interchange between the dry powder and the piezoelectric material; this can increase the amount of energy transferred to the dry powder from the oscillating or vibrating active piezoelectric polymer film so as to cause the dry powder to vibrate at a frequency that is at or near a resonant frequency thereof.

20 In certain embodiments, the elongated channels **101** can be shaped and/or sized to define a resonant chamber or cavity to generate a desired frequency(ies) of oscillation of the piezoelectric polymer material and/or a particular dry powder formulation. That is, each blend or formulation of dry powder may exhibit different flow characteristics that can be accounted for in the geometry design of the elongated
25 channel **101**. The height or depth, length, or width of the channel may be adjusted based on the particular drug or dry powder being administered. Advantageously, the inhaler **10** can be configured to dispense a number of different dry powder packages **100**, each having the potential of having different drug receptacle or blister configurations. For example, the package **100** may be fabricated with 2-10 different
30 standard lengths and a particular drug or formulation and dose matched to one of the predetermined standard lengths based on the closest match to generate an optimum vibration frequency. In other embodiments, the length of the channel and/or other parameters can be custom designed and defined for each formulation or drug that is to

be administered using the inhaler device **10** and the inhaler device **10** can be configured to operate with and/or accommodate each custom package **100**.

Figure 16A illustrates an example of an amplitude-modified vibratory signal **20s** (**Figure 10A**) of a dry powder that can include a kHz carrier frequency (such as about 5kHz-50kHz) modified by low modulating frequency (typically about 10-200Hz) that may be generated and used to dispense a dose of dry powder from a blister channel **101** (**Figure 10A**) as contemplated by certain embodiments of the present invention. The frequency of the vibration can be modified to match or correspond to the flow characteristics of the dry powder substance held in the package to attempt to reach a resonant frequency(s) to promote uniform drug dispersion into the body. In certain embodiments, the vibration of the active piezoelectric surfaces in the channel **101** may be on the order of about 10-200 Hz. In certain embodiments, the frequency may be between at about 10-60Hz. The vibration can be influenced by the amount of active surface and the excitation voltage pulses applied thereto as well as the channel geometry. During dispensing, a channel **101** can be activated by providing a voltage across the piezoelectric layer. In certain embodiments, the voltage provided may be at about 100-400 volts peak-to-peak, typically between about 200-400 volts peak-to-peak. In other embodiments, the voltage can be applied at a different level and at other various frequencies, such as at higher frequencies of between about 25kHz to about 2MHz. Additional suitable excitation signals will be discussed further below.

In certain embodiments, the signal **20s** (shown schematically in **Figures 10A, 10B** with respect to the channel **101**) and/or the vibration of the energy provided to the channel **101** may be configured to concurrently or successively rapidly vibrate the dry powder at a plurality of different frequencies (at similar or different amplitudes) in the range of between about 10 Hz-1000 kHz. In certain embodiments, the frequencies are between about 10-200 Hz, such as 10-60 Hz. In other embodiments, they may be in the range of between about 7kHz-100 kHz, such as 7.5kHz or more such as frequencies between about 15 kHz to 50 kHz.

In particular embodiments, as schematically shown in **Figures 16B-16D**, a non-linear powder-specific dry powder vibratory energy signal **20s** (shown as a different powder specific signal for each of the simulated illustrated formulations shown as "A", "B" and "C") comprising a plurality of selected frequencies can be

generated (corresponding to the particular dry powder being currently dispensed) to output the particular signal corresponding to the dry powder then being dispensed. As used herein, the term “non-linear” means that the vibratory action or signal applied to the package to deliver a dose of dry powder to a user has an irregular shape or cycle, typically employing multiple superimposed frequencies, and/or a vibratory frequency line shape that has varying amplitudes (peaks) and peak widths over typical standard intervals (per second, minute, etc.) over time. In contrast to conventional systems, the non-linear vibratory signal input can operate without a fixed single or steady state repeating amplitude at a fixed frequency or cycle. This non-linear vibratory input can be applied to the blister to generate a variable amplitude motion (in either a one, two and/or three-dimensional vibratory motion). The non-linear signal fluidizes the powder in such a way that a powder “flow resonance” is generated allowing active flowable dispensing.

Figures 16B-16D illustrate three different dry powders **215₁, 215₂, 215₃**, each of which can be analyzed and/or characterized (**20ch₁, 20ch₂, 20ch₃**, respectively). Custom or corresponding individual (non-linear) input signals with frequencies selected from the corresponding characterization that are specifically targeted to that dry powder to facilitate fluidic flow during dispensing can be determined for each dry powder **215₁, 215₂, 215₃**. The drug-specific signals are shown by the signals **20s₁-20s₃**.

The inhalers **10** include signal generating circuitry **10g** therein in communication with the channels **101**. The signal generating circuitry **20g** may be programmed with a plurality of predetermined different signals **20s**, or if the inhaler dispenses only a single dry powder, the signal generator **20** may be programmed with a single signal **20s**. Appropriate powder-specific signals can be determined experimentally and/or computationally at an OEM or evaluation site and input into the inhalers (via hardware and/or software components including programmable processors).

Figures 21A-12E illustrate an example of operations that may be carried out to generate a dry powder-specific signal. A microflow analysis of the dry powder to be dispensed can be performed to assess avalanching flow profiles and/or other suitable mass/time flow profiles. The analysis can be carried out to select predominant oscillatory frequencies for a particular dry powder that, when applied to

the powder during flowable dispensing, can promote uniform mass flow to achieve a fluid-like flow, even for low-density dry powders.

Methods and devices for analyzing rapid powder flow measurement are described in Crowder et al., *Signal Processing and Analysis Applied to Powder behaviour in a Rotating Drum*, Part. Part. Syst. Charact. 16, 191-196 (1999); Crowder et al., *An instrument for rapid powder flow measurement and temporal fractal analysis*, Part Syst Charact 16, pp. 32-34, (1999); and Morales-Gamboa, et al., *Two dimensional avalanches as stochastic Markov processes*, Phys Rev. E, 47 R2229-2232 (1993). See also, Ditto et al., *Experimental control of chaos*, Phys. Rev. Lett., 65: 3211-3214 (1990); B. H. Kaye, *Characterizing the Flow of Metal and Ceramic Powders Using the Concepts of Fractal Geometry and Chaos Theory to Interpret the Avalanching Behaviour of a Powder*, in T.P. Battle, H. Henein (eds.), *Processing and Handling of Powders and Dusts*, The Materials and Metals Society, 1997; B. H. Kay, J. Gratton-Liimatainen, and N. Faddis. *Studying the Avalanching Behaviour of a Powder in a Rotating Disc.*, Part. Part. Syst. Charact. 12:232-236 (1995), and Ott et al., *Controlling Chaos*, Phys. Rev. Lett. 64: 1196-1199 (1990).

Using the principals and relationships described in one or more of these articles with signals derived from analyses of a mass flow and/or microflow, one can determine custom powder specific signals that may be able to achieve uniformly flowing dry powders.

As shown in **Figure 21A**, the time between avalanches, for a particular dry powder of interest, may be evaluated experimentally using a rotating drum. This time information may be converted to frequency space (frequency domain) as shown in **Figure 21B**.

Figure 21C illustrates that a distribution of frequencies **20f** can be determined (computationally or via computer models). Then, a desired number of selected frequencies can be identified. The frequencies selected may span a desired statistically significant percentage of the distribution or be the frequencies most observed in the analysis spectrum. The term “most observed” means those frequencies occurring the greatest number of times in the distribution. For example, the number of different frequencies selected may be at least the three most observed different frequencies and/or sufficient frequencies to represent at least about 50% of the distribution. In certain embodiments, the number can be at least about 5, and

typically about 6, or a number sufficient to represent at least about 75% of the frequency distribution. To select the number, two or three of the most observed frequencies can be used to form the vibration signal. The results can be analyzed experimentally and additional frequencies may be added to the combined non-linear
5 signal to improve fluidic flow performance.

Figure 21D illustrates that six of the most observed frequencies $20f_1$ - $20f_6$, in the distribution plot **20f** can be selected. **Figure 21E** illustrates that the selected frequencies can be superimposed to generate a single superposition signal (that may also include weighted amplitudes for certain of the selected frequencies or
10 adjustments of relative amplitudes according to the observed frequency distribution). Thus, **Figure 21E** illustrates a derived non-linear oscillatory or vibratory energy signal that may be used to dispense a particular dry powder.

Referring again to **Figure 21D**, the signal can be created digitally by computer code means employing mathematical or numerical computation techniques and
15 relevant equations. For example, for a signal **20s** having representative frequencies " f_{1-n} ," the cumulative signal x_{signal} (**20s**, **Figure 21D**) can be generated include a plurality of signal components, xf_1 - xf_n (shown as $20f_1$ - $20f_n$ in **Figure 21D**) at each desired frequency, f_n , each component having an amplitude "a" at its frequency as described below. Using the spectrum shown in **Figure 21D** noting that the most
20 observed frequency in **Figure 21D** is $20f_3$, the following equations may be used to generate the non-linear signal.

For an index, "n" ranging from 0-15,999, used to generate the digital signal:

	$n = [0:15999]$	Equation (1)
25	$xf_3 = \sin(2\pi n/16000)$	Equation (2)
	$xf_2 = af_2 \sin(2\pi n(f_2)/16000(f_3))$	Equation (3)
	$xf_4 = af_4 \sin(2\pi n(f_4)/16000(f_3))$	Equation (4)

This evaluation can be continued for a desired number of frequencies to render
30 a representation of a sufficient number of frequencies /spanning a sufficient portion of the spectrum. The powder-specific, non-linear signal can be generated by summing the selected individual frequency components.

$$x_{\text{signal}} = x_{f_3} + x_{f_4} + x_{f_4} \dots \quad \text{Equation (5)}$$

In certain embodiments, the overall power in the signal, x_{signal} , can be increased by adding a phase shift to one or more of the summed components. For example, for component x_{f_2} , the associated signal contribution can be adjusted by the following equation:

$$x_{f_2} = a_{f_2} \sin(2\pi n(f_2)/16000(f_3) + m\pi/n_f) \quad \text{Equation (6)}$$

Where “m” is the number at this frequency and n_f is the total number of frequencies contained in the signal.

An example of a commercially available rotating drum is the TSI Amherst Aero-Flow™ (TSI Inc. Particle Instruments/Amherst, Amherst, MA). This device provides powder flow information by detecting the occurrence of and recording the time between avalanches. The Aero-Flow™ has been utilized to demonstrate correlation between powder flow and tableting performance for like materials. The instrument uses a photocell detector for its avalanche detection mechanism. A light shines through the plexiglas drum and is obscured from the detector to varying degrees by powder contained in the drum. As the drum rotates, the powder heap rises with the rotation and the photocell detector is uncovered. When an avalanche occurs in the powder heap, the light is again blocked by the cascading powder. The change in light intensity striking the photocell is interpreted by the data collection software as the occurrence of an avalanche. In other embodiments, the occurrence of avalanches can be measured using a sensitive microphone/accelerometer that can be mounted on the rotating drum. Avalanches can be detected acoustically from the sound generated by the avalanching powder. This technique can reduce the amount of powder used, typically to milligram quantities, such as about 10 mg. Statistics of the time between avalanches are determined and an avalanche time phase space plot is generated.

A useful method of presenting data to discover the dynamics of a system is the Poincaré phase space plot. This phase space approach is one in which variables sufficient to describe a system are contained in a single vector. The state of the n variables at an instant in time is a point in phase space. Plotting the time evolution of the system in phase space can map its dynamics. As an example, a simple harmonic

oscillator can be pictured in phase space by plotting the position versus the velocity, variables that completely describe the system. The phase space plot of the harmonic oscillator is a circle reflecting the periodic, but 90 degrees out of phase, exchange of maximum position and velocity. A damped harmonic oscillator would appear as a
5 simple attractor with the trajectory encircling and eventually collapsing to the origin as the position and velocity reach zero. The correlation dimension provides a measure of the space filling properties of the phase space representation. A hypersphere of dimension D and radius r is centered on each data point. The number of data points falling within that sphere as a function of the radius may be displayed in a log-log
10 plot. The slope of the resulting line may be termed the correlation dimension.

To determine an appropriate vibration signal, a suitably sized dry powder sample can be disposed in the drum (such as about 60 ml or less of powder as noted above). The drum can be allowed to rotate through a single revolution before data collection begins so that initial conditions over several powders are similar. The drum
15 can be rotated at 0.5 revolutions per minute for 6 minutes. The photocell voltage signal can be sampled at 25 Hz using a PC based data acquisition board (DI-170, Dataq Instruments, Akron OH). Time between avalanches and the voltage change upon avalanching can be acquired from the voltage signal. A video camera can be situated perpendicular to the drum can record the powder as it rotates in the drum. A
20 grid can be placed behind the drum, without obscuring the photocell, to facilitate determination of the angle of the powder relative to the horizontal. Upon viewing the video, the base and height of the powder heap can be recorded and the angle can be determined using the trigonometric relation, $\theta = \arctan(\text{height}/\text{base})$. Determinations of the instantaneous powder angle can be performed at 200 millisecond intervals.
25 This rate corresponds to every sixth frame of the video, determined previously by recording the counting of a stopwatch.

Angle data time series can comprise at least about 500 data points or 100 seconds. Computation of a Fourier power spectrum can be performed using the Welch method with a 128 point Kaiser window and zero padding to 1024 data points
30 for the FFT calculation. Other suitable methods can be employed as is known to those of skill in the art.

The avalanche statistics can be presented in terms of the mean and standard deviation of time between avalanches. A phase space plot can be generated by

plotting the n^{th} time to avalanche against the $(n-1)^{\text{th}}$ time to avalanche. For the angle of repose, phase space plots consist of the instantaneous deviation from the mean angle versus the first time derivative of the angle. The rate of change of the angle at each data point can be approximated from the preceding and subsequent data points using Newton's method.

The uniformity of flow can be discerned by examining the frequency and the amplitude of the oscillations. Certain dry powder signals may exhibit a higher degree of variability in frequency and in amplitude relative to others. By use of the Fourier transform (FT) power spectrum, energy distributions can be obtained. Energy spectrums that are dispersed over a range of frequencies can indicate more irregular flow. The mean time to avalanche can be subtracted from the instantaneous time to avalanche to deconvolute relevant frequency data in angle phase space plots. Identifying the predominant frequencies and selectively combining and/or using those identified frequencies as the basis of the transmitted vibration energy excitation signal may induce resonance in the dry powder during dispensing.

Alternatively, the non-linear signal can be determined experimentally as described in co-assigned, co-pending U.S. Patent Application Serial No. 60/440,513, the contents of which was incorporated by reference hereinabove. Generally described, a flow channel housing having an angularly adjustable elongate flow channel therein can be used to determine appropriate powder-specific signals. A dry powder of interest (which may be a low density dry powder) can be introduced into the elongate flow channel. The flow channel can be vibrated to thereby vibrate the dry powder to cause the dry powder to fluidly flow out of the channel via an exit port. The flow channel can include a flexible piezoelectric polymer over which the dry powder flows; the piezoelectric polymer can be electrically stimulated to flex upwardly to cause it to vibrate the powder as the powder travels along and through the flow channel. As described above, the vibration can be carried out using a non-linear excitation signal having a carrier frequency and a modulation frequency. In certain embodiments, the carrier frequency can be between about 2.5kHz-50kHz and modulation frequency may be between about 10-500Hz. In any event, flow characteristics can be experimentally evaluated, typically over several different input signals at different frequencies, and at least one frequency (and/or angular orientation of the flow path) selected for its ability to generate reproducible fluidic flow of dry

powder based on the flow characteristics exhibited during the vibrating step. The orientation of the flow channel can be adjusted so that the flow channel is angularly offset (with the dispensing port located lower than the input port) in the axial direction with respect to the horizontal and vertical axis. In certain embodiments, the flow
5 channel is adjusted to be at different selected angles during the evaluation to consider the impact that the angle may have on the dispensing flow.

In any event, in certain embodiments, the output signals **20s** used to activate the piezoelectric channels **101** may include a plurality, typically at least three, superpositioned modulating frequencies and a selected carrier frequency. The
10 modulating frequencies can be in the range noted herein (typically between about 10-500 Hz), and, in certain embodiments may include at least three, and typically about four superpositioned modulating frequencies in the range of between about 10-100Hz, and more typically, four superpositioned modulating frequencies in the range of between about 10-15Hz.

Figure 10A illustrates one embodiment of an elongate channel **101**. The
15 channel **101** has a length that is greater than its width. In certain embodiments, the length may be at least twice the distance of the width. As shown, the elongate channel **101** includes a ceiling **120** and a floor **100f**. The floor **100f** includes a metallic material layer **100m** thereon. The ceiling **120** can be configured to be
20 preferentially pre-disposed to separate at a desired location **120s** as noted above. Referring to **Figure 9**, the metallic region **100m** on the channel **101** is in communication with a metal trace **100t** that extends a distance away from the channel **101** and, in operation, can engage a power source and relay the input signal from the signal generator circuitry **20g**.

25 Increased numbers of doses may be held on a single disposable package **100**, whether symmetrically aligned or offset one to another on a single primary surface, or formed on opposing primary surfaces (the package can be flipped to access the underside portion of doses). In certain embodiments, about 50-100 discrete doses or more can be held on the package **100** (not shown).

30 **Figure 10B** illustrates that the channel **101** can be configured so that the floor **100f** slopes or descends a distance over the length of the channel **101** so that the downstream end of the channel **101** during dispensing and/or the region more proximate the preferentially predisposed separation portion has a greater depth. This

can allow gravity to help move the powder along the length of the channel **101**, allowing the dry powder to contact a greater active amount of active or vibrating piezoelectric polymer surface area. As such, the elongated channels **101** contemplated by embodiments of the present invention may amplify the vibration frequency of the dry powder before it is released to the user. In yet other
5 embodiments, the cavity of the channel can narrow and/or become more shallow as it approaches the end portion that is proximate the mouth of the user during dispensing (**Figure 17A**).

Figure 11 illustrates another embodiment of the present invention. In this
10 embodiment, a sensor that can detect one or more patient-air flow related parameters *in situ* during each dispensing, can be incorporated directly into the disposable multi-dose packaging **100**. As shown, each blister **101'** or channel **101** (**Figure 1**) can have a proximately positioned airflow parameter sensor circuit **150**. The circuit **150** includes conductive traces **150t** and a sensor **150s** that can detect air pressure
15 differential or airflow rate. If the sensor **150s** detects air pressure differential, this can be compared to predetermined airflow rate information, such as *a priori* knowledge of the inhaler's airflow resistance to determine inspiratory capacity of the user. This data can be analyzed in the controller and the energy applied to the blister or channel adjusted. In certain embodiments, the sensor **150s** can be a hot-wire anemometer that
20 is mounted to the package **100** so that it is in fluid communication with the user during operation and powered via the metallic traces **150t** when connected to the power source. In other embodiments the piezoelectric polymer layer **28** can define a pressure sensor that detects pressure differential based on its flexure and relay the signal to the controller (not shown).

Figures 12A and 12B illustrates that a plurality of individual multi-dose
25 packages **100a**, **100b** can be stacked in a tier configuration. In the embodiment shown, two packages are stacked, but three, four, or more may also be stacked according to embodiments of the present invention. The dry powder filled blisters **101** can be oriented so as to be in the same or opposing directions package-to-
30 package. In the embodiment shown in **Figure 12B**, the blisters are channels **101** and are disposed in package **100a** with the arcuately curved portion **101a** oriented downward while the lower package **100b** is held with the arcuately curved portion **101a** oriented upward. The orientations of the channels can be reversed or placed to

both face up or down or even alternated on each particular package **100a**, **100b** (not shown). The packages **100a**, **100b** can include the same or different channel layout and/or can be angularly offset about an axis extending normal to the packages **100a**, **100b** and through the centers thereof, when positioned in the inhaler **10**. For
5 example, the top package **100a** may be rotated so that the underlying channels are misaligned by 5, 30, 45, 60, 90, or 120 degrees or more. Further, a plurality of discrete channels **101** can be provided so that they are aligned end to end in a radially spaced apart configuration (**Figure 12C**).

In certain embodiments, each package, or blisters **101** on a particular package
10 **100**, may be filled with the same dry powder products, while in other embodiments, each package may be filled with different formulations of dry product (and may have different blister geometry). In certain particular embodiments, the inhaler **10** can be configured so that the packages **100** can provide a combination therapy of two or more different drugs that can be administered concurrently or separately to a subject.

15 As shown by the two-way arrows in **Figures 12A** and **12B**, the stacked tier package configuration can be spring loaded in the inhaler **10** so that the two packages **100a**, **100b** can be compressed toward each other at activation and the powder in a channel on the top package **100a** can be concurrently released with the powder in a corresponding channel on the bottom package **100b**. The packages **100a**, **100b** can
20 then be released to move away from each other decompressing the spring during non-active dispensing.

Figure 13 illustrates a thin strip package **100s** with a plurality of elongated channels **101** positioned along its length. The strip package **100s** may be scrolled along two tension rods **200a**, **200b** as shown to position the dispensing portion in the
25 desired location in the inhaler (advancing the used empty blisters similar to a camera film cartridge). In certain embodiments, as shown in **Figure 13**, two side-by-side scrolled strips **100s**, **100s** can be employed. This side-by-side arrangement may be particularly suitable for combination therapies or deliveries as described above. In other embodiments, the scrolled strips **100s** may be placed in a stacked tier one above
30 the other (not shown).

Figures 14A and **14B** illustrate yet another embodiment of a blister package arrangement. As shown, the package **100sp** is vertically undulated and/or spiraled. The adjacent tiers can be coaxially aligned or adjacent tiers or levels can be disposed

off center or horizontally offset from the others. The tiers can be arranged in a serpentine arrangement from top to bottom (or side-to-side if oriented laterally instead of longitudinally as shown) to provide spaced apart dry powder blisters channels **101** in spaced apart tiers. The spiral or serpentine arrangement can be provided by
5 arranging a plurality of discrete packages in the desired configuration, by configuring one or more strips or sheets in a spiral configuration and/or by folding a single sheet or strip over on itself to take on a serpentine shape.

Figures 15A-15C illustrate an additional embodiment of an inhaler **10'**. As shown, the body of the inhaler **10'** has a hinge **10h** along one edge portion connecting
10 two housing members **11a**, **12b** and allowing access to the interior cavity **10c**. The top housing member **11a** holds the mouthpiece **20** and associated inhalation port **18**. The bottom member **12b** can hold the electronics module **40** (**Figure 15B**). As described above, the inhaler **10'** houses the dry powder blister package **100**. The top housing member **11a** may include a spring-loaded connector **13** that facilitates a snug
15 connection between the housing members **11a**, **12b**, mouthpiece and package **100** when closed and can also provide a conductive connection **13c** to the top surface of the blister traces **100t**. As shown, the mouthpiece **20** can include an aperture **20a** that will overlie a blister region **101** on the package **100** when the inhaler **10'** is closed. As shown in **Figure 15A**, the package **100** can include a central air aperture **102** that
20 allows air to travel in the cavity **10c**. The mouthpiece **20** can be configured to rotate (noted by the arrow in **Figure 15A**) about the top housing member **11b** so that it can serially overlie each filled blister for inhalation.

The package **100** can include a tab **100t** (shown as a notch or cut-out region along the perimeter of the package) that fits into the housing in a desired location to
25 facilitate proper loading in the housing **12b**. **Figure 15B** illustrates the closed shape and **Figure 15C** illustrates the blister package **100**.

Figures 17A and 17B illustrate another embodiment of a blister **100b** with an elongate channel **101**. In this embodiment, the blister **100b** includes both upwardly and downwardly extending portions. The downwardly extending portion **100d** is an
30 elongate lower channel **101** and the upwardly extending portion **100u** is a protrusion that can be substantially arcuate and positioned to reside over a forward portion of the blister **100b** with the upstream ceiling **120** portion being substantially planar over the remainder of the underlying channel **101**.

As shown by the arrow in **Figure 17A**, a dose release member **299** can be disposed in the inhaler **10** so as to approach the blister channel **101** from under the floor **100f** of the package **100**. As shown by the arrow in **Figure 17B**, the release member **299** can then return to its static position to be subsequently actuated again for a next release. The release member **299** can be configured with an end portion **299e** that has a shape or profile that is substantially the same as the top blister portion **100u** of the ceiling **120** overlying the channel **101** in the target release zone. The release member **299** can be configured to puncture, slit, slice, burst, burn, puncture, pierce, melt, or otherwise separate or form the release port or opening in the target region of the floor **101f**.

In the embodiment shown in **Figures 17A** and **17B**, both the upper portion of the release member **299e** and a portion of the ceiling **120** have a substantially upwardly arching or arcuate profile. In certain embodiments, the upper portion **299e** may be semi-spherical. In operation, as shown in **Figure 17B**, the upper portion of the release member **299** advances to contact and invert the lower portion of the blister (*i.e.*, the loose region of the floor **100l**) into the upper blister or ceiling thereby creating a relatively large exit port for the dry powder to exit the channel. The configuration of the release member **299** may reduce the likelihood that the loose end of the floor material will fold back or otherwise impede the release of powder during administration.

In the embodiment shown in **Figures 17A**, **17B** and **18A-18E**, the target opening region **100r** may be a forward portion of the floor **100f**. The floor **100f** can be formed from and/or include the active piezoelectric polymer material (referred to generally as feature **28**) so that, in operation, the floor **100f** can flex in response to the applied signal **20s** to impart the active delivery vibration energy to the dry powder. In other embodiments, the release region **100r** can be formed in a floor that is non-active, such as a foil and/or polymer layer and the ceiling **120** can be formed from the piezoelectric polymer material **28** with the ceiling **120** configured to flex to impart the desired dispersion energy to the dry powder. Combinations of the above may also be employed.

Figure 18A illustrates the top of one package **100** configuration that can operate as described for **Figures 17A** and **17B**. **Figures 18B** and **18C** illustrate opposing top and bottom primary surfaces of the package **100** shown in **Figure 18A**.

Figures 18C and 18D illustrate that the elongate channel **101** may have a curvilinear outer profile when viewed from the top that narrows in width from the rear of the channel **101r** to the forward portion of the channel **101fr**. In addition, the rear portion **101r** can have a greater depth (as well as a larger cross-width) than the forward portion **101fr**. As shown, the elongate channel **101** may be configured as a substantially pear-shaped dry powder basin or reservoir. **Figure 18E** is shown without the top blister ceiling **120** and illustrates the release member **299** in position as it forms the opening or release region **100r** in the floor **100f** of the channel **101**. In operation, the ceiling **120** upstream of the blister **100b** can remain intact. The inhaler **10** may be configured with an exit port that is in fluid communication with the package bottom of the blister **100d** (not shown).

Figures 19A and 19B illustrate another embodiment of a blister **100b** with an elongate channel **101** with the release member **299** configured to open the blister **100b** from the ceiling **120** of the package. The arrows in **Figures 19A and 19B** illustrate the direction of movement relative to the package **100** orientation. As discussed with respect to **Figures 17A, 17B, and 18A-18E**, in this embodiment, the blister **100b** can include both upwardly and downwardly extending protrusion portions **100u, 100d**. As before, the downwardly extending portion **100d** can be formed as a depression that defines the elongate (lower) channel **101** and the upwardly extending portion **100u** can be formed as a protrusion that may be substantially arcuate and positioned to reside over a forward portion of the blister **100b** with the upstream ceiling **120** portion being substantially planar over the remainder of the underlying channel **101**. The release member forward portion **299e** can be configured with a profile that corresponds to the shape of the floor **100f** or channel **101** at the lower portion of the blister **100d**. The forward contact portion **299e** may have a profile that is semi-spherical and/or when viewed from the side, it may have a profile that is substantially arcuate or semi-circular. In operation, as shown in **Figure 19B**, the release member **299** can invert the profile of the loose end **100r** created by the opening in the ceiling portion **100u** so that it substantially blends with and/or conforms to the shape of lower blister **100d** as shown in **Figure 19B**. That is, the loose edge portion can extend away from the direction of flow but is configured so that it resides proximate the bottom of the channel **101** so that it does

not impede the dry powder flow out of the channel **101**. The floor **100f** of the channel may include the piezoelectric polymer material **28**.

Figure 20A illustrates the release member **299** positioned over the package **100** with a series of blisters **100b** having openings or release zones **100r** that have
5 been (serially) opened by the release member **299**. **Figure 20B** illustrates the top or ceiling side of the package **100** shown in **Figure 20A**. **Figure 20C** illustrates another elongate channel **101** configuration for the floor **100f** that forms the bottom portion of the blister **100d**. As shown in **Figure 19B** and **Figure 20D**, in this embodiment, the elongate channel **101** can have a substantially constant depth along its length. **Figure**
10 **20E** shows the channel **101** from the top with the ceiling **120** substantially transparent except about the opening **100r** for clarity.

It is noted that, in operation, depending on how the package **100** and release member **299** are oriented in the inhaler **10**, the release member **299** may approach the package **100** from the top or side so that it engages the package ceiling **120** proximate
15 the blister **100b** (such as shown for the embodiment shown in **Figures 19A** and **19B**) or bottom or opposing side (such as for the embodiment shown in **Figures 17A** and **17B**) so that it engages the package floor **100f** proximate the blister **100b**.

In operation, a priming signal can be applied to the blister **100b** prior to forming the opening in the blister **100b** to vibrate the dry powder held therein to the
20 lowest portion of the elongate flow channel, which can be described as a blister reservoir or basin **101b**. The release member **299** can be directed to open the blister **100b** during or after application of the priming signal. The priming signal may be the same signal as the active delivery signal **20s** or may be a different signal.

The release member **299** may be configured as any suitable device for
25 inserting or forming the opening in the blister **100b**. The release member **299** can be configured to pierce, puncture, slice, melt, or otherwise form the opening in the blister. The release member **299** can include a blade, a laser, pressurized fluid, acoustic energy, or other release or separation means. The release member **299** may be spring loaded to automatically actuate upon a user's depression of a dispensing
30 mechanism.

To facilitate dry powder administration through the inhaler port, the active dispensing signal **20s** can be applied to the vibrating layer substantially instantaneous (*i.e.*, during) with the introduction of the opening **100r** in the blister **100b**. In other

embodiments, the signal **20s** can be applied before the opening **100r** is formed (typically within about 50ms) or shortly after the opening is introduced into the blister (typically within about 50ms).

In certain embodiments, each blister **100b** can have its own operative
5 electrical parameter and associated electrical connections that engage with a central control unit in the inhaler **10** and can be used to verify proper operative alignment. That is, an electronics module with signal generating circuitry **20g** can communicate separately with the electrical traces **100t** proximate each blister region **101** to sense a desired electrical parameter such as capacitance of the piezoelectric polymer blister.
10 In other embodiments, the sensed parameter can be an open connection in the electrical path indicating improper alignment.

In particular embodiments, such as for rotating mouthpiece configurations, the device can be configured with a plurality of predefined stops (recesses, projections, etc...) that allow the mouthpiece **20** to click into position in a manner that yields an
15 audible or tactile verification by the user at each dispensing blister (not shown).

In certain embodiments, the piezoelectric polymer material, shown generally as element **28** in **Figures 9 et seq.**, and which is included in the blister packages **100** of embodiments of the invention, is formed from a piezoelectrically active material such as PVDF (known as KYNAR piezo film or polyvinylidene fluoride) and its
20 copolymers or polyvinylidene difluoride and its copolymers (such as PVDF with its copolymer trifluoroethylene (PVDF-TrFe)).

In particular embodiments, the piezoelectric polymer material layer **28** is a thin film PVDF. As used herein, the term "thin film" means that the piezoelectric polymer layer **28** is configured as a structurally flexible or pliable layer that can be
25 sized to be about 10-200 μ m thick. In certain embodiments, the piezoelectric polymer layer can be sized to be less than about 100 μ m thick, and more typically, about 20-60 μ m thick.

As noted above, selected regions of the piezoelectric polymer material can be coated or layered with a conductive material to form a desired conductive pattern.
30 The conductive regions (at least portions of the blister regions) of the package **100** define the active regions and can be individually or selectively activated during operation. Laminates of PVDF and another material capable of being formed into and hold a desired blister shape and/or powder channel may be particularly suitable

for forming the active blister configurations. Suitable laminates include thin film layers of PVDF united to thin layers of one or more of aluminum, PVC and nylon films. The PVDF may form the bottom, top, or an intermediate layer of the laminated material structure. For intermediate layer configurations, vias and/or edge
5 connections can be used to apply the electric signal to the blister piezoelectric material.

The metal trace patterns can be provided by applying a conductive pattern onto one or more of the outer faces of the piezoelectric substrate layer. For depositing or forming the metal, any metal depositing or layering technique can be employed
10 such as electron beam evaporation, thermal evaporation, painting, spraying, dipping, or sputtering a conductive material or metallic paint and the like or material over the selected surfaces of the piezoelectric substrate (preferably a PVDF layer as noted above). Of course, alternative metallic circuits, foils, surfaces, or techniques can also be employed, such as attaching a conductive mylar layer or flex circuit over the
15 desired portion of the outer surface of the piezoelectric substrate layer **28**. It is preferred that, if flex circuits are used, they are configured or attached to the substrate layer **28** so as to be substantially transparent to the structure of the sensor array to minimize any potential dampening interference with the substrate layer **28**. It is also noted that while particular conductive patterns are illustrated in the figures, the
20 present invention is not limited thereto, as alternative conductive patterns may also be used.

Typically, upper and lower surface metal trace patterns are formed on opposing sides of the piezoelectric polymer material but do not connect or contact each other. For example, conductive paint or ink (such as silver or gold) can be
25 applied onto the major surfaces of the package about the elongated channels and associated metal traces such that it does not extend over the perimeter edge portions **28e** of the piezoelectric substrate layer **28**, thereby keeping the metal trace patterns on the top and bottom surfaces separated with the piezoelectric substrate layer **28** therebetween. This configuration forms the electrical excitation path when connected
30 to a control system to provide the input/excitation signal for creating the electrical field that activates the deformation of the piezoelectric substrate layer **28** during operation. As such, the electrical path for each elongated channel **101** extends via the respective upper and lower transmission lines to the electrical terminations operably

connected to the controller. The excitation circuit (signal generating circuitry 20g) configuration can be such that the upper trace operates with a positive polarity while the lower trace has a negative polarity or ground, or vice versa (thereby providing the electric field/voltage differential to excite the piezoelectric substrate in the region of the selected channel 101). Of course, the polarities can also be rapidly reversed during application of the excitation signal (such as + to -, or + to -) depending on the type of excitation signal used, thereby flexing the piezoelectric material in the region of the receptacle portion. For a more complete discussion of the active excitation path or configuration, *see* U.S. Patent Application Publication No. 2006/0191534 to Hickey et al.

In certain embodiments, methods for fabricating a multi-dose disposable dry powder blister package include: (a) providing a thin layer of piezoelectric polymer material; (b) concurrently forming a plurality of elongated projections having a width and an associated length into the piezoelectric polymer material; and (c) applying a metallic material to selected regions of at least one primary surface of the piezoelectric polymer material so as to cover at least a portion of each of the plurality of projections. For mass production applications, the forming step can be carried out by fabricating a shaping, forming, or molding tool that defines the channel geometry for each package. The tool can have raised projections and/or depressed formations. The forming step can be carried out by stamping the piezoelectric polymer material or the laminated material, which comprises the piezoelectric polymer material, onto the tool or the tool onto a layer or layers of piezoelectric polymer materials. Thus, in certain embodiments, the forming step is carried out by pressing the (which may be a laminated configuration) piezoelectric polymer material over a shaping tool having a plurality of raised projections thereon. The conductive material can be applied before or after the channel geometry forming step. The conductive material may be applied by applying a metallic coating onto a molding tool having a plurality of raised projections with a metallic coating and contacting the piezoelectric material with the molding/shaping tool to thereby transfer the metallic coating onto the desired surface (surfaces) of the elongated projections of the piezoelectric polymer material. Other methods of depositing the conductive pattern may be employed as described above.

In operation, generally described, the dry powder inhalers of the present invention have integrated, active energy piezoelectric polymer substrate multi-dose

drug packages that generate patient-assisted dispersal systems. The inhalers can be used for nasal and/or oral (mouth) respiratory delivery. The inhalable dry powder dose is packaged in a multi-dose dry powder drug package that includes a piezoelectric polymer substrate (such as PVDF) that flexes to deform rapidly and provide mechanical oscillation in an individually selectable signal path on the package. The signal path directs the signal to the region of the drug receptacle or well to cause the well to oscillate in cooperation with a user's inspiratory effort, and, thus, actively direct the dry powder out of the well and up into the exit flow path. The airflow rate and/or volume of a patient can be measured *in situ* dynamically during administration and the DPI can include a control system that provides adjustable energy output to the active piezoelectric polymer substrate dispersal element responsive to a user's inspiratory capabilities. In addition, the DPI control system may be a multi-purpose system that can administer a plurality of different types of dry powder substances, or formulations, such as different drugs. As such, the control system may be configured to adjust the energy delivered to the piezoelectric polymer substrate based on the type of substance and/or the flowability of the dry powder substance or drug being administered. The energy may be adjusted *in situ* based on considering both the user's inspiratory effort and the type of substance being administered. As a result, the powder can be actively dispersed into the exit flow path of the inhaler during the user's inspiratory activity without using pressurized propellants such as CFC's.

In addition, the piezoelectric polymer material may be configured as two piezoelectric polymer film layers separated by an intermediately positioned pliable core, all of which are concurrently deformable to flex by the application of voltage thereacross.

Figure 22 is a block diagram of exemplary embodiments of data processing systems that illustrates systems, methods, and computer program products in accordance with embodiments of the present invention. The processor **410** communicates with the memory **414** via an address/data bus **448**. The processor **410** can be any commercially available or custom microprocessor. The memory **314** is representative of the overall hierarchy of memory devices containing the software and data used to implement the functionality of the data processing system **405**. The

memory 414 can include, but is not limited to, the following types of devices: cache, ROM, PROM, EPROM, EEPROM, flash memory, SRAM, and DRAM.

As shown in **Figure 22**, the memory 414 may include several categories of software and data used in the data processing system 405: the operating system 452;
5 the application programs 454; the input/output (I/O) device drivers 458; the powder specific (vibratory) signal generator module 450; and the data 456. The data 456 may include a plurality of dry powder data 451 corresponding to particular or target signal parameters for each dry powder and/or patient inspiratory data, which may be obtained from an operator or stored by the inhaler and/or timing data that defines the
10 metered dose amounts, flow rates, and open time for the dispensing port (allowing automatic control of the dispensing operation, dependent on the dry powder being dispensed). As will be appreciated by those of skill in the art, the operating system 452 of the inhaler and/or programmable inputs thereto may be any operating system suitable for use with a data processing system, such as OS/2, AIX, OS/390 or
15 System390 from International Business Machines Corporation, Armonk, NY, Windows CE, Windows NT, Windows95, Windows98 or Windows2000 from Microsoft Corporation, Redmond, WA, Unix or Linux or FreeBSD, Palm OS from Palm, Inc., Mac OS from Apple Computer, LabView, or proprietary operating systems. The I/O device drivers 458 typically include software routines accessed
20 through the operating system 452 by the application programs 454 to communicate with devices such as I/O data port(s), data storage 456 and certain memory 414 components and/or the dispensing system 420. The application programs 454 are illustrative of the programs that implement the various features of the data processing system 405 and preferably include at least one application which supports operations
25 according to embodiments of the present invention. Finally, the data 456 represents the static and dynamic data used by the application programs 454, the operating system 452, the I/O device drivers 458, and other software programs that may reside in the memory 414.

While the present invention is illustrated, for example, with reference to the
30 powder-specific signal generator module 450 being an application program in **Figure 22**, as will be appreciated by those of skill in the art, other configurations may also be utilized while still benefiting from the teachings of the present invention. For example, the module 450 may also be incorporated into the operating system 452, the

I/O device drivers **458** or other such logical division of the data processing system **405**. Thus, the present invention should not be construed as limited to the configuration of **Figure 22**, which is intended to encompass any configuration capable of carrying out the operations described herein.

5 The I/O data port can be used to transfer information between the data processing system **405** and the inhaler dispensing system **420** or another computer system or a network (*e.g.*, the Internet) or to other devices controlled by the processor. These components may be conventional components such as those used in many conventional data processing systems which may be configured in accordance with
10 the present invention to operate as described herein.

 While the present invention is illustrated, for example, with reference to particular divisions of programs, functions and memories, the present invention should not be construed as limited to such logical divisions. Thus, the present invention should not be construed as limited to the configuration of **Figure 22** but is
15 intended to encompass any configuration capable of carrying out the operations described herein.

 The flowcharts and block diagrams of certain of the figures herein illustrate the architecture, functionality, and operation of possible implementations of dry powder-specific dispensing and/or vibratory energy excitation means according to the
20 present invention. In this regard, each block in the flow charts or block diagrams represents a module, segment, or portion of code, which comprises one or more executable instructions for implementing the specified logical function(s). It should also be noted that in some alternative implementations, the functions noted in the blocks may occur out of the order noted in the figures. For example, two blocks
25 shown in succession may in fact be executed substantially concurrently or the blocks may sometimes be executed in the reverse order, depending upon the functionality involved.

 In certain embodiments, the powder specific vibration energy signals are non-linear and the inhaler can include computer program code that automatically
30 selectively adjusts the output of the vibration energy signal based on the identified dry powder being dispensed. The vibration energy output signals for the dry powders being dispensed can be based on data obtained from a fractal mass flow analysis or

other suitable analysis of the dry powder being administered to the user. The inhaler may be particularly suited to dispense low-density dry powder.

The foregoing is illustrative of the present invention and is not to be construed as limiting thereof. Although a few exemplary embodiments of this invention have
5 been described, those skilled in the art will readily appreciate that many modifications are possible in the exemplary embodiments without materially departing from the novel teachings and advantages of this invention. Accordingly, all such modifications are intended to be included within the scope of this invention as defined in the claims. In the claims, means-plus-function clauses, where used, are intended to cover the
10 structures described herein as performing the recited function and not only structural equivalents but also equivalent structures. Therefore, it is to be understood that the foregoing is illustrative of the present invention and is not to be construed as limited to the specific embodiments disclosed, and that modifications to the disclosed embodiments, as well as other embodiments, are intended to be included within the
15 scope of the appended claims. The invention is defined by the following claims, with equivalents of the claims to be included therein.

THAT WHICH IS CLAIMED:

1. A dry powder inhaler, comprising:

an elongate body defining a substantially enclosed cavity and having opposing upper and lower primary surfaces, the elongate body having a width dimension and a length dimension, the length dimension being greater than the width dimension, the length dimension extending between opposing first and second ends of the elongate body, the width dimension extending normal to the length dimension between opposing sides of the elongate body;

a multi-dose disk located in the cavity of the elongate body, the disk holding a plurality of doses of an inhalable dry powder;

a mouthpiece with an inhalation port residing at the first end of the elongate body between the upper and lower primary surfaces so as to be externally accessible by a user while the elongate body remains closed, the inhalation port configured to be in fluid communication with at least one of the doses of dry powder during use; and

a cover member having an upper surface that is attached to the elongate body to pivot about an axis of rotation that is substantially normal to the upper primary surface, wherein the axis of rotation is longitudinally offset from a center of the length dimension of the elongate body to reside closer to the second end of the elongate body while being substantially centered in the width dimension, wherein the cover member rotates between a closed position to overlie the mouthpiece during periods of non-use and an open position away from the mouthpiece during periods of use to allow a user to access the inhalation port while the elongate body remains closed, and wherein the cover member rotates from the closed position to the open position about the axis of rotation so that the upper surface of the cover member remains substantially parallel to the upper primary surface of the elongate body.

2. A dry powder inhaler according to Claim 1, wherein the cover member has a substantially planar upper surface that overlies the upper primary surface of the elongate body, and wherein the cover member upper surface has an aperture that extends downwardly therethrough that surrounds the axis of rotation.

3. A dry powder inhaler according to Claim 2, wherein the aperture is a circular

aperture.

4. A dry powder inhaler according to Claim 1, wherein the cover member has a planar first end portion that overlies the upper primary surface and an arcuate second end portion, wherein the arcuate portion of the second end portion extends downward over the mouthpiece on the first end of the elongate body when in the closed position.

5. A dry powder inhaler according to Claim 1, wherein the elongate body includes matable upper and lower shells that remain closed during use, and wherein the cover member is configured to be able to pivot toward a side of the inhaler elongate body to overhang the elongate body such that an inner portion of a length of the cover member upper surface remains over the upper primary surface of the elongate body while an outer portion of the length of the cover member extends beyond a perimeter of the elongate body.

6. A dry powder inhaler according to Claim 1, wherein the upper and lower primary surfaces of the elongate body are substantially planar, wherein the cover member upper surface has a planar portion residing above the upper primary surface of the elongate body, the cover member planar portion having an aperture extending downwardly therethrough, the aperture surrounding the axis of rotation.

7. A dry powder inhaler according to Claim 1, wherein the axis of rotation is normal to and extends through a window that provides a user visual access to the multi-dose disk, and wherein the window is defined by aligned apertures in the cover member upper surface and the upper primary surface of the elongate body.

8. A dry powder inhaler according to Claim 1, further comprising an indexing mechanism in the elongate body that rotates the multi-dose disk, and wherein the disk has stops or detents that provide tactile and/or audible feedback to a user to verify that the disk is in a desired dispensing position.

9. A dry powder inhaler according to Claim 1, wherein the elongate body has a substantially planar portion that comprises a window that allows visual access to a portion of

the multi-dose disk, wherein the cover member upper surface comprises an aperture that is aligned with the window, and wherein the axis of rotation extends through and is normal to the window.

10. A dry powder inhaler according to Claim 9, wherein the multi-dose disk comprises externally visible indicia of a dose number that is visible through the window during use.

11. A dry powder inhaler according to Claim 1, wherein the inhaler includes at least one of a visible or audible alert that warns a user when the multi-dose disk approaches empty.

12. A dry powder inhaler according to Claim 1, wherein the elongate body has a thin profile when viewed from the side with the upper and lower primary surfaces being substantially planar, and wherein the cover member upper surface has a substantially planar portion with an outwardly projecting mound portion, the outwardly projecting mound portion configured to overlie an activation button on the elongate body upper primary surface when the cover member is closed to inhibit inadvertent activation.

13. A dry powder inhaler according to Claim 1, wherein, with the cover member in the closed position, the inhaler has a thin profile with substantially flat upper and lower primary surfaces that is sized to fit into a pocket of a garment worn by a user.

14. A dry powder inhaler according to Claim 1, wherein the inhalable dry powder is a low density dry powder, and wherein the inhalable dry powder held in the multi-dose disk comprises active ingredient particulate sizes of between about 0.5-8.0 μm .

15. A dry powder inhaler according to Claim 1, wherein, in the open position, the cover member pivots about the axis of rotation and has a length sufficient to overhang the side of the inhaler such that an inner portion of a length of the cover member upper surface remains over the upper primary surface of the elongate body while an outer portion of the length of the cover member extends beyond a perimeter of the elongate body.

16. A dry powder inhaler, comprising:
- an inhaler housing body defining a substantially enclosed cavity;
 - a multi-dose disk located in the cavity of the housing body, the disk holding a plurality of circumferentially spaced apart doses of an inhalable dry powder;
 - a mouthpiece with an inhalation port supported by the housing body so as to be externally accessible by a user while the housing body remains closed, the inhalation port configured to be in fluid communication with at least one of the doses of dry powder during use; and
 - a cover member that is attached to an upper primary surface of the housing body to be able to pivot about an axis of rotation that is substantially normal to the upper primary surface of the housing body, wherein the cover member has a planar upper surface that overlies the upper primary surface of the housing body when closed, wherein the axis of rotation is substantially centered in a width dimension of the housing body, and wherein the cover member rotates between a closed position to overlie the mouthpiece during periods of non-use and an open position away from the mouthpiece during periods of use to allow a user to access the inhalation port while the housing body remains closed,
- wherein the housing body is an elongate body and the mouthpiece resides on one end of the elongate body between upper and lower primary surfaces, and wherein the axis of rotation is longitudinally offset to reside closer to an end of the housing body without the mouthpiece, and wherein the cover member rotates from the closed position to the open position about the axis of rotation so that the upper surface of the cover member remains substantially parallel to the upper primary surface of the elongate body.

17. A dry powder inhaler according to Claim 16, wherein the housing body has substantially planar upper and lower primary surfaces, wherein the cover member upper surface is planar and that overlies the upper primary surface of the housing body when closed, and wherein the cover member planar upper surface has an aperture extending downwardly therethrough that surrounds the axis of rotation.

18. A dry powder inhaler according to Claim 16, wherein, in the open position, the cover member pivots to a side of the inhaler about the axis of rotation and has a length

sufficient to overhang the side of the inhaler such that an inner portion of a length of the cover member upper surface remains over the upper primary surface of the elongate body while an outer portion of the length of the cover member extends beyond a perimeter of the elongate body.

19. A dry powder inhaler according to Claim 16, further comprising an indexing mechanism in the elongate body that rotates the multi-dose disk, and wherein the disk has stops or detents that provide tactile and/or audible feedback to a user to verify that the disk is in a desired dispensing position.

20. A dry powder inhaler, comprising:

an elongate body having opposing first and second outer primary surfaces with a substantially enclosed cavity therebetween and having opposing top and bottom end portions;

a multi-dose sealed blister package holding a plurality of discrete metered doses of a dry powder inhalable product located in the cavity of the elongate body;

an inhalation port extending through a mouthpiece in the bottom end portion of the elongate body so as to be externally accessible by a user while the elongate body remains closed, the inhalation port configured to be in fluid communication with at least one of the discrete metered doses during use; and

a cover member that is pivotally attached to the elongate body and rotates between a first closed position to overlie the inhalation port and mouthpiece at the bottom end portion of the body during periods of non-use and a second open position away from the inhalation port during periods of use to expose the inhalation port and mouthpiece and allow a user to access the inhalation port on the bottom end of the elongate body while the elongate body remains closed, wherein the cover member has a length and width sufficient to extend from the bottom end to proximate the top end portion of the inhaler body when the cover is in the closed position, and wherein the cover has a first end portion with an arcuate profile that extends downwardly substantially conformally over the inhaler bottom end when in the closed position.

21. A dry powder inhaler according to claim 20, wherein the elongate body is a substantially closed body that remains closed during use with the cover member rotating away to allow a user access to the inhalation port and mouthpiece, wherein the elongate body

has rounded top and bottom end portions, wherein the mouthpiece has a contour with a radius of curvature that is substantially the same as adjacent portions of the inhaler elongate body, and wherein the cover member width is less than a width of the elongate body and snugly abuts the mouthpiece when in the closed configuration, and wherein the cover member pivots toward a side of the inhaler elongate body to move to the open position with a planar pivoting portion of the cover member remaining on and contacting the first primary surface of the inhaler elongate body both in the open and closed positions.

22. A dry powder inhaler according to claim 20, wherein the cover member has opposing first and second end portions, the first end portion being pivotally attached to the first primary surface of the elongate body proximate a top end portion of the inhaler, the cover member having a substantially planar profile that merges into the second end portion with a lower portion thereof that turns and extends toward an opposing end of the inhaler.

23. A dry powder inhaler according to claim 22, wherein the cover member comprises a mound that cooperates with the elongate body to define an air pocket between an underlying activation switch and the mound.

24. A dry powder inhaler according to claim 20, wherein the first primary surface of the elongate body comprises a window that overlies a portion of the multidose package, and wherein the cover member comprises an aperture that is aligned with the window, and wherein the cover member is pivotally attached to the elongate body to pivot about an axis that extends through and normal to the window and rotates about the window.

25. A dry powder inhaler according to claim 24, wherein the multidose package comprises externally visible indices of a dose number that are visible through the window during use.

26. A dry powder inhaler according to claim 20, wherein the multidose package includes at least one of a visible or audible alert warning that alerts the user when the multidose package approaches the last few remaining doses.

27. A dry powder inhaler according to claim 20, wherein the elongate body further comprises a depressible user activation button accessible via the first primary surface and a dose advancing knob on a side of the elongate body in communication with the multi-dose package whereby the multi-dose package can be rotated.

28. A dry powder inhaler according to claim 27, wherein the first outer primary surface is a planar top surface and the second outer primary surface is a planar bottom surface of the inhaler, wherein the elongate body has a thin profile when viewed from the side with the mouthpiece having a contour that blends with a contour of the bottom end portion of the elongate body, and wherein the cover member is substantially planar with an outwardly projecting mound portion, the outwardly projecting mound portion configured to overlies the activation button on the first primary surface of the elongate body when the cover member is closed over the inhalation port to inhibit inadvertent activation.

29. A dry powder inhaler according to claim 20, wherein with the cover member in the closed position, the inhaler has a thin profile with substantially flat first and second outer primary surfaces, rounded top and bottom ends, and parallel long sides that define a substantially oval perimeter shaped pocket-sized inhaler that fits into the pocket of a garment worn by a user.

30. A dry powder inhaler according to claim 20, wherein the mouthpiece defines a portion of an outer surface of the inhaler and is releaseably attached to the elongate body bottom end portion thereby allowing periodic cleaning or replacement, and wherein the inhaler elongate body has a curvilinear recessed neck that is sized and configured to releaseably attach to the mouthpiece.

31. A dry powder inhaler according to claim 20, further comprising:
control circuitry held in the elongated body; and
a battery operatively associated with the control circuitry, wherein the control circuitry is configured to generate an amplitude-modified non-linear signal corresponding to a priori flow characteristics of a dry powder being dispensed to selectively vibrate powder in a selected blister held by the multi-dose blister package.

32. A dry powder inhaler according to claim 31, wherein the non-linear signal comprises a plurality of predetermined superimposed frequencies selected according to a priori flow characteristics of the dry powder being dispensed.

33. A dry powder inhaler according to claim 31, wherein the control circuitry is configured to detect a predetermined electrical parameter associated with the position of one of a plurality of elongate channels of the multi-dose package with respect to the inhalation port to affirm proper alignment before allowing active dispersion of the corresponding dry powder dose.

34. A dry powder inhaler according to claim 33, wherein the multi-dose blister package has blisters that comprise piezoelectric polymer material, and wherein the electric parameter comprises capacitance of the piezoelectric polymer material.

35. A dry powder inhaler according to claim 31, wherein the multi-dose blister package has blisters that comprise piezoelectric polymer material, and wherein, in operation, the control circuitry is configured to apply the electrical input so that an excitation voltage differential is transmitted to cause said piezoelectric polymer material to flex thereat to promote resonance of the dry powder and actively disperse a dry powder pharmaceutical drug through the inhalation port.

36. A dry powder inhaler according to claim 31, wherein the multi-dose blister package comprises:

a platform body comprising at least one piezoelectric polymer material layer forming at least a portion of each of a plurality of spatially separated discrete blisters having elongate dry powder channels having an associated length, width and height; and

a conductive pattern configured on the platform body so as to be in communication with the control circuitry, the conductive pattern being attached to selected portions of the piezoelectric polymer material including each of the regions corresponding to the blisters to define active energy releasing vibratory channels, wherein, in operation, the control circuitry generates an electrical input that is transmitted via the conductive pattern to flex the

piezoelectric polymer material associated with at least one selected blister and vibrate the dry powder in the associated at least one elongate channel.

37. A dry powder inhaler according to claim 20, wherein the inhalable dry powder is a low density dry powder with active ingredient particulate sizes of between about 0.5-8.0 μm .

38. A dry powder inhaler according to claim 20, wherein the inhaler comprises a dose releasing member with a forward edge portion that has a shape that corresponds to a shape of a semi-spherical portion of a blister ceiling on the multi-dose package.

39. A dry powder inhaler according to claim 20, wherein the multi-dose package has blisters with elongate blister channels for holding the dry powder having an internal cavity profile, the inhaler further comprising a dose releasing member disposed in the inhaler to advance toward and retract away from a ceiling side of the multi-dose package, and wherein the dose releasing member has a forward edge portion that has a shape that corresponds to a shape of the cavity profile.

40. A dry powder inhaler according to claim 20, wherein the mouthpiece is non-protruding and has a contour that is a continuation of adjacent sides of the inhaler elongate body to define a continuous rounded contour of the bottom end of the inhaler.

41. A dry powder inhaler according to claim 20, wherein the cover member pivots to be able hang over both a top end of the inhaler, the top end residing away from the inhalation port on a bottom end of the inhaler, and long sides of the inhaler.

42. A dry powder inhaler according to claim 20, wherein the cover member conceals an activation button on the first primary surface when in the closed position and exposes the activation button when in the open position.

43. A dry powder inhaler according to claim 20, wherein the inhaler comprises an indexing mechanism that rotates the blister package, and wherein the blister package has

stops or detents that cooperate with the inhaler body to provide tactile and/or audible feedback to a user to verify that the blister package is in a desired dispensing position.
