## (54) SPECIAL VIDEO EFFECT GENERATOR

(71) We, RCA CORPORATION, a Corporation organized under the laws of the State of Delaware, United States of America, of 30 Rockefeller Plaza, City and State of New York, 10020, United States of America, do hereby declare the invention, for which we pray that a patent may be granted to us, and the method by which it is to be performed, to be particularly described in and by the following statement:—

This invention relates to a generator to produce a television signal which has the artistic effect obtained live by viewing moving objects with the sole illumination being a high intensity strobe light. This type of illumination is often used on stage or at parties to produce a subjective effect of discontinuous motion. In practice, this well known device pulses a high intensity strobe lamp from some source such as a pulse generator. When used as a sole illumination in a dark room, its sharp, short pulses of light cause the eye to retain frozen images of any moving object, giving the illusion of discontinuous motion. This invention provides means for achieving the same subjective result in any television image whether it comes from a live camera or a prerecorded source.

The recent advent of all-electronic digital field stores and frame stores has made practical the "electronic snapshot" whereby a single frame of, for example, some critical sports action may be snatched in real time from the continuous video signal and presented as a still picture for close inspection. In all known prior art application the concept has been limited to a "single snapshot", taken at the discretion of the operator and held for an indeterminate period. Then again at the discretion of the operator, the store is terminated and live video is again applied to the output line.

In accordance with the present invention, a discontinuous motion special effects generator for television is provided including memory means responsive to a television video signal for storing signals representing a television picture field and memory control

means for controlling the writing into, and for continuously reading out of, said memory the stored picture fields. The generator further includes means for automatically providing control pulses at a predetermined rate for providing during said read-out the special effect of discontinuous motion, and means being second control means coupled to the memory control means and responsive to the control pulses for causing the stored field which is read out of the memory to change only in response to these control pulses.

Embodiments of the invention are now described in conjunction with the drawings, in which:—

Figure 1 illustrates a special effects video generator according to one embodiment of the present invention in combination with a memory system for producing the desired special effect of discontinuous motion.

Figure 2 is a set of waveforms useful in illustrating the operation of the system of Figure 1.

Figure 3 is another embodiment of the present invention for producing the special effect of discontinuous motion in synchronism with audio.

Referring to Figure 1, a memory system 11 outlined in dashed lines is presented in block form. This memory system 11 includes, for example, a memory 15 and a memory control 27. The memory system 11 may be, for example, a digital video synchronizer such as RCA type TFS-121, sold by RCA Broadcast Systems, Commercial Communication Systems Division, Front and Cooper Streets, Camden, New Jersey.

Basically, the memory system 11 accepts television video signals from an external source connected to terminal 17 and stores these video signals in a memory 15. The stored video signals in the memory 15 are read out at the video output terminal 19. The memory control 27 provides control signals to the memory 15 to control the writing of the video signal into the memory 15 and the reading of the information in the memory to the video output terminal 19.

This reading and writing information is done on a field-by-field basis by writing a complete television field into the memory and then reading this field out of the memory. The 5 memory 15 of the memory system 11 may include means for converting the video signals from analog to digital format and may further include a D to A converter to convert back to analog. The memory 15 may include 10 circuits for developing address codes to store the picture information and read address codes for reading and circuits for providing local reference subcarrier, horizontal and vertical sync so that the picture 15 information is timed with respect to a local sync generator. All of the above type of functions are achieved in the referenced RCA type synchronizer. The memory control 20 27 is designed so that in response to a low level at its input terminal 33 it will provide a write control signal via lead 21 to the memory 15 which will cause the writing of the new video information at terminal 17 into the memory 15 and allow the subsequent 25 reading of that information from the memory 15. The reading out of the memory is controlled by a read control signal provided from memory control 27 to memory 15 via lead 22. When the write inhibit input level 30 to terminal 33 of the memory control 27 is at a high level, a control signal is applied via lead 21 to the memory 15 and no new video is stored into the memory. When the voltage at the write control lead inhibits the 35 new video into the memory 15, the read control signal causes the video output read from the memory to be a continuous reproduction of the last field written into the memory. This may be done in various ways 40 depending upon the type of memory. In one type of memory, this is done by simply reading the stored information in the memory and in another type of memory the information is recirculated and rewritten into the memory before being read out of the 45 memory.

The artistic effect similar to that obtained by a high intensity strobe lamp — the illusion of discontinuous motion wherein the eye 50 retains frozen images — is achieved by the circuit illustrated in Figure 1 in combination with the memory system 11, when the video signal information at the input terminal 17 is representative of moving objects. A variable 55 pulse generator 23 which may typically be set at a rate of the order of 1 to 2 pulses per second repetition rate is coupled when switch 25 is closed to an OR gate 45. The output of OR gate 45 is coupled to a toggle 60 flip-flop 47. The pulses from generator 23 are short duration toggle or trigger type pulses. Toggle flip-flop 47 may be, for example, a J-K flip-flop as described on Page 15-10 of "Handbook for Electronics 65 Engineering Technicians" by Milton

Kaufman and Arthur H. Seidman. This type of flip-flop changes state on the occurrence of a pulse at clock or toggle

input C. The Q output terminal of flip-flop 47 is coupled to the D input of delay D-type flip-flop 49. A D-type flip-flop 49 is described on Page 15-12 of the above cited handbook. This type of flip-flop provides the level at the Q terminal which corresponds with the level at the D input terminal on the occurrence of a pulse at the clock or toggle input C. Vertical sync pulses are applied to the C or clock (toggle input) of the D-type flip-flop 49 via terminal 35. The Q output terminal of the D-type flip-flop 49 is coupled to the terminal 33 of memory

control 27. The  $\bar{Q}$  output terminal of flip-flop 49 is coupled via delay inverters 51 and 52 to OR gate 45. Also applied to the OR gate 45 is the output from a variable debounce circuit 43. A push button switch 41 is coupled to a debouncing circuit 43. The switch 41 with the circuit 43 produces a toggle pulse at the output of the debouncing circuit each time the button of switch 41 is depressed. The de-bounce circuit 43 in response to the momentary closure of push button switch 41 produces a clean output pulse without the ringing usually associated with the momentary closure of the push button switch.

Referring to Figures 1 and 2, when switch 25 is closed, toggle pulses 31 at 1 pulse per second rate (waveform A of Fig. 2) for example are provided through OR gate 45 to the first flip-flop 47 causing the output at

terminal  $\bar{Q}$  of flip-flop 47 to go to a low state 105 as indicated at point 37 in waveform B of

Fig. 2. This low at  $\bar{Q}$  terminal of flip-flop 47 provides a low at D terminal of D-type

110

flip-flop 49. The Q and  $\bar{Q}$  outputs of flip-flop 49 remain however in the previous state until the arrival of a pulse (pulse 38 in waveform C of Fig. 2) to the C input of this flip-flop. The arrival of a vertical toggle 115 pulse, (vertical sync) at the C input of second flip-flop 49 causes Q output terminal of this flip-flop to go low (see point 39 of waveform D of Fig. 2) providing a low at terminal 33. This low at terminal 33 causes 120 the memory 15 to start writing or storing new input video at the beginning of the field. The

Q output of the second flip-flop 49 goes high when Q goes low and that high level is applied through delay inverters 51 and 52 to the input of OR gate 45. The high at OR gate 45 causes a high level signal or toggle pulse at the toggle input C of the first flip-

5 flop 47 causing the  $\bar{Q}$  output of the first flip-flop 47 to go to a high level as indicated at point 41 in waveform B of Fig. 2. This provides a high level to the D input of the second flip-flop 49. With the arrival of the next vertical sync pulse to the C input of second flip-flop 49, the output of the Q terminal of this flip-flop goes to a high level (see point 42 of waveform D of Fig. 2) causing a high at terminal 33 and a write inhibit control signal to be applied to the memory 15. The memory 15 ceases writing or storing new information and the last 10 written video field in the memory is repeatedly read out of the memory 15. In this state, the system provides the same fixed or "frozen" image. On the occurrence of the second pulse 31a from generator 23, the 15 operation as discussed above reoccurs and a low is provided to memory control 27 in synchronism with the next vertical sync pulse at terminal 35 to cause the writing or 20 storing of a single field of the new video 25 present at terminal 17. The Q high level from flip-flop 49 again through delays 51 and 52 causes in response to the next vertical sync pulse at terminal 35 a high level at the Q terminal of flip-flop 49. The high level at the input memory of control 27 provides the inhibit to the video input and video output returns to the "frozen" image until the 30 occurrence of another pulse from generator 35 23. This writing of updated video and freezing reoccurs with new or updated video occurring at the repetition rate of the generator producing the desired special effect of 40 discontinuous motion similar to that produced on stage by viewing moving objects with the sole illumination being a strobe light. The repetition rate of the generator 23 may be selected to be similar to that of the strobe light. This special effect may be 45 stopped simply by opening switch 25. A continuous-freeze image or a manually switched freeze image may be provided with switch 25 open by depressing switch 41. Each time switch 41 is depressed, the operation 50 is similar to that which occurs when a single pulse 31 is applied from generator 23, namely, a single new field of video is written into the memory with the system automatically returning to the "freeze" condition on 55 the occurrence of the next vertical sync pulse.

55 Switch 61 is provided in Figure 1 to connect terminal 33 to ground when closed. This provides a continuous low into the system when closed causing continuous video to be written into and read out of the memory system. With switch 61 open as 60 illustrated in Figure 1, the memory system is under the control of the logic circuit of Figures 1 or 3.

A very useful modification to the basic information is shown in Figure 3 wherein a low-pass filter extracts from the audio signal at terminal 70 the low frequency components representing the rhythm of the music accompanying the video signal. This low frequency audio signal is converted to a pulse by clipping and shaping circuit 73, and the resultant pulse is applied when switching 75 is closed as one of the inputs to the OR gate 45. The "frozen" pictures will then appear at a rate synchronous with the audio; more specifically, at a rate synchronous with the beat of the music.

80

## WHAT WE CLAIM IS:—

1. A discontinuous motion special effects generator system for television comprising: memory means responsive to a television video signal for storing signals representing a television picture field, memory control means for controlling the writing into, and for continuously reading out of, said memory the stored picture field, first control means for automatically providing control pulses at a predetermined rate for providing during said readout the special effect of discontinuous motion, and second control means coupled to said memory control means and responsive to said control pulses for causing the stored field, which is read out of the memory to change only in response to said control pulses.

85

2. Generator system as claimed in Claim 1 wherein said second control means includes means coupled to said memory control means responsive to said control pulses for causing the writing into said memory of a single picture field of video only on the occurrence of each control pulse.

100

3. Generator system as claimed in Claim 1 or 2 wherein said first control means includes a pulse generator.

105

4. Generator system as claimed in Claim 3 wherein said pulse generator has a pulse repetition rate on the order of 1 to 2 pulses per second.

110

5. Generator system as claimed in Claim 1 or 2 wherein said first control means includes means responsive to audio signals for producing control signals.

115

6. Generator system as claimed in Claim 5 wherein said means responsive to said audio signal includes a low pass filter for passing the low frequency components representing the rhythm of music that may be accompanying the video.

120

7. Generator system as claimed in Claim 5 including a clipping circuit coupled to the output of said low pass filter.

125

8. A discontinuous motion special effects generator system for television comprising: memory means responsive to a television video signal for storing signals representing a television picture field, memory control

130

means for controlling the writing into and for continuously reading out of said memory means the stored picture field, first control means for providing control pulses at a rate 5 determined by the frequency components of audio signals accompanying the television signal, and second control means coupled to said memory control means and responsive to said control pulses for causing the stored 10 field which is read out of the memory to change only in response to said control pulses.

9. The system of Claim 8 wherein said control means includes means for changing

the stored readout in synchronism with the 15 rhythm of music.

10. The system of Claim 9 wherein said control means includes a low pass filter.

11. A discontinuous motion special 20 effects generator system for television, substantially as hereinbefore described with reference to Figure 1 or Figure 3.
