TETRAHYDROTHIENO PYRIDINE DERIVATIVES AS DDRs INHIBITORS

FIELD OF THE INVENTION

The present invention relates to compounds inhibiting Discoidin Domain Receptors (DDR inhibitors), methods of preparing such compounds, pharmaceutical compositions containing them and therapeutic use thereof.

The compounds of the invention may be useful for instance in the treatment of many disorders associated with DDR mechanisms.

BACKGROUND OF THE INVENTION

Discoidin Domain Receptors (DDRs) are type I transmembrane receptor tyrosine kinase (RTKs). The DDR family comprises two distinct members, DDR1 and DDR2.

DDRs are unique receptors among the other members of the RTK superfamily, in that DDRs are activated by collagen whereas other members of the RTK superfamily are typically activated by soluble peptide-like growth factors (see Vogel, W. (1997) Mol. Cell 1, 13–23; Shrivastava A. Mol Cell. 1997; 1:25–34.). Moreover, DDRs are unusual RTKs also because they form ligand-independent stable dimers that are non-covalently linked (see Noordeen, N. A.(2006) J. Biol. Chem. 281, 22744–22751; Mihai C. J Mol Biol. 2009; 385:432–445).

The DDR1 subfamily is composed of five membrane-anchored isoforms, and the DDR2 subfamily is represented by a single protein. The five DDR1 isoforms all have in common the extracellular and transmembrane domains but differ in the cytoplasmic region (see Valiathan, R. R. (2012) Cancer Metastasis Rev. 31, 295–321; Alves, F. (2001) FASEB J. 15, 1321–1323).

DDR receptor family has been found involved in a series of fibrotic diseases, such as pulmonary fibrosis, and in particular idiopathic pulmonary fibrosis (IPF). The first evidence for a protective role of DDR1 deletion in lung fibrosis was generated in 2006 by the research group of Dr. Vogel (see Avivi-Green C, Am J Respir Crit Care Med 2006;174:420–427). The authors demonstrated that DDR1-null mice were largely protected against bleomycin (BLM)-induced injury. Furthermore, myofibroblast expansion and apoptosis were much lower in these animals compared with their wild-

type counterparts. Absence of inflammation in knockout mice was confirmed by lavage cell count and cytokines ELISA. These results indicated that DDR1 expression is a prerequisite for the development of lung inflammation and fibrosis.

DDR2 deficiency or downregulation reduces bleomycin-induced lung fibrosis (see Zhao H, Bian H, Bu X, Zhang S, Zhang P, Yu J, et al Mol Ther 2016; 24:1734–1744). Zhao et al, demonstrated that DDR2 plays a critical role in the induction of fibrosis and angiogenesis in the lung, in particular that DDR2 synergizes with transforming growth factor (TGF)-β to induce myofibroblast differentiation. Furthermore, they showed that treatment of injured mice with specific siRNA against DDR2 exhibited therapeutic efficacy against lung fibrosis. In a second publication, Jia et al showed that mice lacking DDR2 are protected from bleomycin-induced lung fibrosis (see Jia S, Am J Respir Cell Mol Biol 2018;59:295–305. In addition, DDR2-null fibroblasts are significantly more prone to apoptosis than wild-type fibroblasts, supporting a paradigm in which fibroblast resistance to apoptosis is critical for progression of fibrosis.

Some compounds have been described in the literature as DDR1 or DDR2 antagonists.

WO2016064970 (Guangzhou) discloses tetrahydroisoquinoline-7-carboxamides as selective DDR1 inhibitors useful as therapeutic agents for preventing and treating inflammation, liver fibrosis, kidney fibrosis, lung fibrosis, skin scar, atherosclerosis and cancer.

Of note, antagonizing the DDR receptors may be useful for the treatment of fibrosis and disease, disorder and conditions that result from fibrosis and even more antagonizing both receptors DDR1 and DDR2 may be particularly efficacious in the treatment of the above-mentioned disease, disorder and conditions.

Several efforts have been done in the past years to develop novel DDR1 and DDR2 receptor antagonists useful for the treatment of several disease and some of those compounds have shown efficacy also in humans.

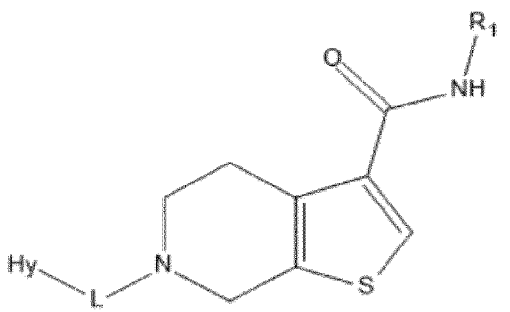

Despite the above cited prior art, there remains a potential for developing selective inhibitors of both receptors DDR1 and DDR2 useful for the treatment of diseases or conditions associated with a dysregulation of DDR receptors, in the respiratory field, in particular idiopathic pulmonary fibrosis (IPF), to be administered by the inhalation route and characterized by a good inhalatory profile, that corresponds to a good activity in the

lung, a good lung retention and to a low metabolic stability in order to minimize the systemic exposure and correlated safety issues.

In this direction, we have surprisingly found a new series of compounds of general formula (I), as herein below reported, that solves the problem of providing inhibitors for receptors DDR1 and DDR2 for administration by inhalation, that are active as selective inhibitors of DDR1 and DDR2 receptors with respect to other human protein kinases. These compounds show high potency, good inhalatory profile, low metabolic stability, low systemic exposure, improved safety and tolerability.

As above indicated, the present invention refers to a series of compounds represented by the general formula (I) as herein below described in details, which are endowed with an inhibitory activity on receptors DDR1 and DDR2. Antagonizing receptors DDR1 and DDR2 can be particularly effective in the treatment of those diseases where the DDR receptors play a role, such as fibrosis and disease, disorder and condition related to fibrosis.

Indeed, as detailed in the experimental part below, the compounds of formula (I) of the present invention are able to act as inhibitors of both DDR1 and DDR2 receptors in a substantive and effective way. In particular, Table 5 below shows that for the compounds of the present invention, both the affinity for either DDR1 and DDR2 receptors and the inhibitory activity against either DDR1 and DDR2 receptors are below about 80 nM respectively in the binding (expressed as Ki) and the cell based assays (expressed as IC50). This confirms that the compounds of formula (I) are able to inhibit the two isoforms of DDR receptor mainly involved in fibrosis and diseases resulting from

fibrosis. Accordingly, the compounds of formula (I) can be used in the treatment of fibrosis, in particular pulmonary fibrosis, when DDR1 and DDR2 are involved.

As indicated in the experimental part, comparative examples, in particular in Table 6, it is shown that, conversely to the comparative compound of Example C1, characterized by lacking a linker between the tetrahydrothieno pyridine ring and the Hy group, the presence of a $-CH_2-$ or $-C(O)-$ linker in that position in the present invention compounds unexpectedly and remarkably determines a relevant increase in the inhibitory activity on the DDR1 and DDR2 receptors.

Furthermore, as indicated in the same experimental part, data demonstrate that, conversely to the compound of Example C2, characterized by the absence of a linker between the tetrahydrothieno pyridine ring and the Hy group and by the -C(O)NH- group substitution at the α position with respect to sulphur atom, instead of the β position as in Example 3 of the present invention, the presence of the above mentioned linker concurrently with the substitution at the β position in the present invention compounds unexpectedly and noteworthy determines a relevant increase in the inhibitory activity against the DDR1 and DDR2 receptors.

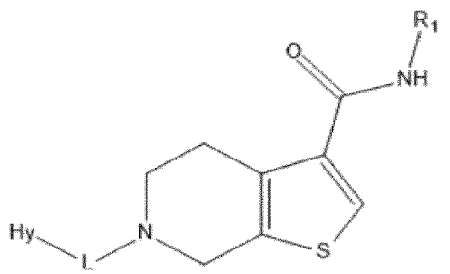

Advantageously, the compounds of the present invention are endowed with a very high potency, they could be administered in human at a lower dosage respect to the compounds of the prior art, thus reducing the adverse events that typically occur administering higher dosages of drug.

In addition to being notably potent with respect to their inhibitory activity on both receptors DDR1 and DDR2, the compounds of the present invention are also characterized by being selective inhibitors of DDR1 and DDR2 receptors with respect to other human protein kinases, by a good inhalatory profile, that permits to act effectively on the lung compartment and have, at the same time, a low metabolic stability, that allows to minimize the drawbacks associated with the systemic exposure, such as safety and tolerability issues.

Therefore, the compounds of the present invention are particularly appreciated by the skilled person when looking at suitable and efficacious compounds useful for the treatment of fibrosis, in particular idiopathic pulmonary fibrosis, administered by the inhalation route and characterized by a good inhalatory profile, that corresponds to a good

activity on the lung, a good lung retention and to a low metabolic stability, that minimizes the systemic exposure and correlated safety issues.

According to Scheme 1, Intermediate III may be prepared following a one-step synthesis starting from intermediate II, under direct amidation of esters (transamidation) conditions, using for example butyllithium as a promoter in a suitable organic solvent, such as THF or Dioxane, at a temperature ranging from -78 °C to room temperature for few hours. Intermediate IV can be obtained from intermediate III under suitable deprotection conditions, using for example aqueous HCl or HCl in Dioxane or TFA, in a suitable solvent, such as DCM, at a suitable temperature ranging from 0°C to room temperature. Applying suitable alkylation conditions with the appropriate alkylbromide intermediate XII, for example using a suitable base, such as DIPEA or TEA, in a suitable solvent, such as DMF or DMA, at room temperature, compounds of formula (I) can be obtained.

Alternatively, intermediate III can be prepared from intermediate II performing an hydrolysis using a suitable aqueous inorganic base, such as NaOH, in a suitable solvent, such as MeOH, at room temperature, followed by an amide coupling with the proper amine VIII or IX, under suitable amide coupling conditions, in the presence of an agent that activates the carboxylic acid partner, such as TBTU or HATU or T3P, and in the presence of an organic base such as DIPEA or TEA, in a suitable organic solvent, such as DCM or DMF, and at a temperature generally around room temperature.

Alternatively, intermediate III can be prepared from intermediate II via amidation in the presence of TCFH and 1-methylimidazole to give the transient activated acylimidazolinium intermediate that is reacted with the appropriate amine VIII or IX in a solvent such as DMF, at RT. In a different approach, intermediate III can be prepared from intermediate II the presence of an appropriate chlorinating reagent, such as $POCl_3$ or thionyl chloride or oxalyl chloride, in a solvent such as pyridine or cyclopentylmethylether in the presence of a catalytic amount of DMF, at a temperature ranging from 5°C to room temperature, to get the corresponding acyl chloride that is treated directly with the appropriate amine VIII or IX.

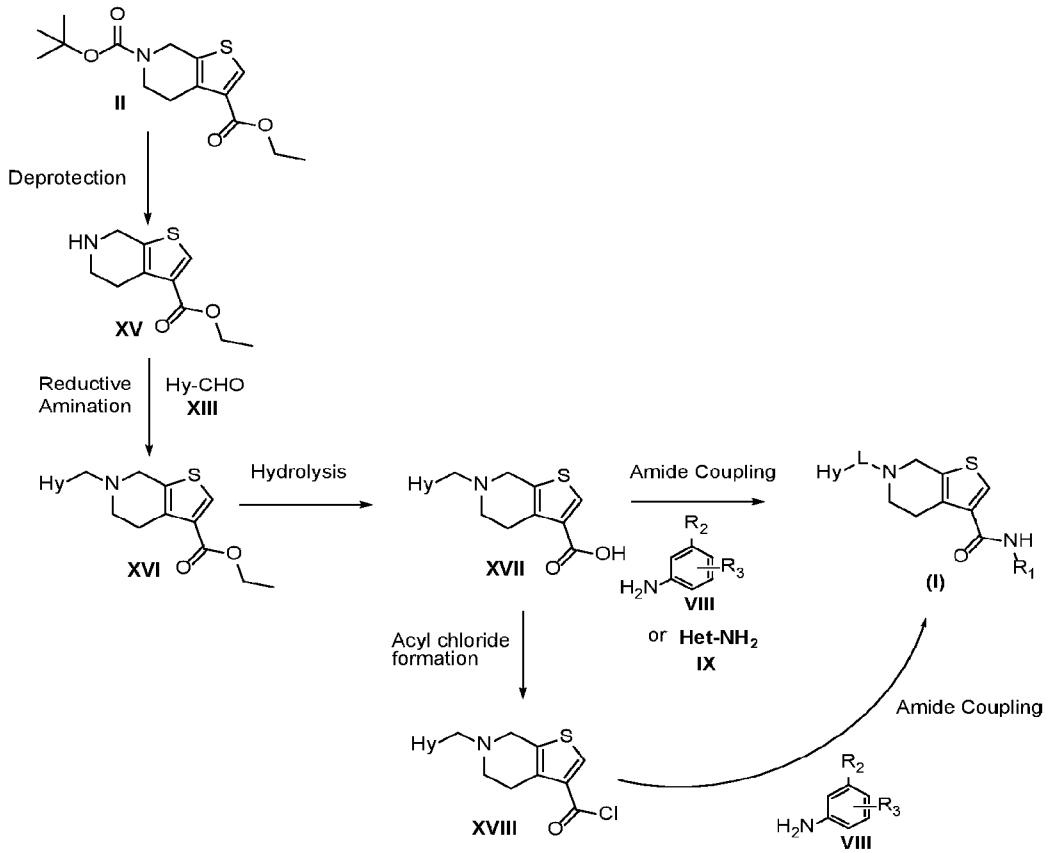

Differently, intermediate IV can be converted into intermediate V applying reductive amination conditions with the appropriate aldehyde X, with a suitable reducing agent, such as $Na(OAc)_3BH$ or $NaCNBH_3$, in a suitable solvent, such as DCM or EtOH, in the presence of an acid, such as acetic acid, and in the presence of a dehydrating agent, such as magnesium sulfate, if needed, or in the presence of a suitable coordinating agent, such as titanium tetrahydroisopropoxide, if needed, at a temperature ranging from room

temperature to 50°C. Intermediate V can be converted into compounds of formula (I) performing a Buchwald-Hartwig cross-coupling with the appropriate amine using the suitable palladium catalyst, such as RuPhos Pd G3, and the suitable base, such as cesium carbonate, in a suitable solvent, such as DMF or Dioxane. Alternatively, Intermediate V can be converted into compounds of formula (I) performing a Pd-catalyzed amide N-arylation with the appropriate amide, using the suitable palladium catalyst, such as $Pd(dba)_2$, with a suitable ligand, such as XantPhos, in a suitable solvent, such as toluene, in the presence of a catalytic amount of aluminium triflate, at a temperature of 110°C.

In a different approach, intermediate VI can be prepared from intermediate V applying the suitable reductive amination conditions described above with the appropriate aldehyde XI and subsequently transformed into compounds of formula (I) via amidation with the proper acylchloride XIV using the suitable base, such as TEA or DIPEA, in a suitable solvent, such as THF, at room temperature. Compounds of formula (I) can also be obtained from intermediate IV following reductive amination conditions described above and using the appropriate aldehyde XIII. Differently, compounds of formula (I) can be prepared from intermediate IV via amidation with the proper carboxylic acid, applying the conditions described above.

In another embodiment, compounds of formula (I) may be prepared according to Scheme 2.

Scheme 2

According to Scheme 2, intermediate XV can be obtained from intermediate II under suitable deprotection conditions, using for example aqueous HCl or HCl in Dioxane or TFA, in a suitable solvent, such as DCM or Diethyl Ether at a suitable temperature ranging from 0°C to room temperature. Intermediate XV can undergo reductive amination to afford intermediate XVI, with the appropriate aldehyde XIII, with a suitable reductant agent, such as $Na(OAc)_3BH$ or $NaCNBH_3$, in a suitable solvent, such as DCM or EtOH, in the presence of an acid, such as acetic acid, and in the presence of a dehydrating agent, such as magnesium sulfate, if needed, or in the presence of a suitable coordinating agent, such as titanium tetrahydroisopropoxide, if needed, at a temperature ranging from room temperature to 50°C. Subsequently, compounds of formula (I) can be prepared from intermediate XVI performing an hydrolysis using a suitable aqueous inorganic base, such as NaOH, in a suitable solvent, such as MeOH, at room temperature, followed by an amide coupling with the proper amine VIII or IX, under suitable amide coupling

conditions, in the presence of an agent that activates the carboxylic acid partner, such as TBTU or HATU or T3P, and in the presence of organic base such as DIPEA or TEA, in a suitable organic solvent such as DCM or DMF, and at a temperature generally around room temperature. Alternatively, compounds of formula (I) can be prepared from intermediate XVII the presence of an appropriate chlorinating reagent, such as $POCl_3$ or thionyl chloride or oxalyl chloride, in a solvent such as pyridine or cyclopentylmethyl ether, if needed, in the presence of a catalytic amount of DMF, if needed, at a temperature ranging from 5°C to 50°C, to get the corresponding acyl chloride XVIII that may undergo an amide coupling with the appropriate amide VIII using the proper base, such as TEA, in a proper solvent, such as DCM, at around room temperature.

Intermediate 10 (1 g, 3.28 mmol) and HATU (4.982 g, 13.10 mmol) were weighed into a reaction tube which was backfilled with argon (x3). DCM (24.56 ml) and DMF (8.19 ml) were added to the reaction mixture followed by DIPEA (9.16 ml, 52.4 mmol). The reaction mixture was stirred for 30 mins and 3-(tert-butyl)-1-methyl-1H-pyrazol-5-amine (0.502 g, 3.28 mmol) was added and the reaction was heated to 45C and stirred until LC-MS indicated consumption of starting material. Further additions of HATU and DIPEA were necessary to obtain complete conversion. The reaction mixture was then extracted with DCM/H_2O (x3) and the combined organic layers washed with 1:1

NaCl(sat):H_2O solution followed by brine. The combined organic layers were then concentrated under vacuum to yield the crude material which was purified via flash column chromatography (0-50% EtOAc/Hexane. Product eluted at 50% EtOAc) to give title compound (1.13 g, 2.70 mmol, 82 % yield).

PHARMACOLOGICAL ACTIVITY OF THE COMPOUNDS OF THE INVENTION

In vitro Assays

Binding Assays

DDR1 and DDR2 binding assays were performed using Life Technologies LanthaScreen™ Europium Kinase Binding assay. The compounds were incubated with 5 nM DDR1 (Carna Biosciences) or 5 nM DDR2 (Life Technologies) for 1 hour at room temperature in white 384-well OptiPlate (PerkinElmer), containing 20 nM or 10 nM Kinase Tracer 178 respectively and 2 nM Europium labelled anti-GST antibody (Life Technologies) in assay buffer (50 mM HEPES pH 7.5, 10 mM MgCl2, 1 mM EGTA and 0.01% BRIJ35).

The ratio of fluorescence emission 665 nm/ 615 nm after excitation at 340 nm was obtained using the Tecan Spark 20M plate reader. IC50 values were determined in GraphPad Prism 7.0 software, using 4 parameter model: log(inhibitor) vs. response. IC50 values were converted in Ki using the Cheng-Prusoff equation (Ki=IC50/(1+[Tracer]/Kd).

DDR1 cell based assay

The inhibition of DDR1 receptor activation by compounds was evaluated by PathHunter® U2OS DDR1 assay (Eurofins DiscoverX), according to the manufacturer's instructions. Briefly, U2OS-DDR1 cells were seeded in white 384-well plates at a density

of 5000 cells/well and incubated for 2 hours at 37°C and 5% CO_2. Cells were then treated with compounds at different concentrations and incubated for 30 minutes, before stimulation with bovine Type II Collagen 20 µg/ml and incubation overnight at 37°C and 5% CO_2. PathHunter Detection Reagents were prepared according to the protocol provided by DiscoverX and 20 µl/well of this mix were added to each well. After incubating the plates for 1 hour at room temperature in the dark, luminescence signal was acquired with a plate reader. Raw data were normalized to vehicle control (0% for normalization) and positive control (100% for normalization; cells treated with 20 µg/ml collagen II) and IC50 parameters were calculated in GraphPad Prism 8.0 software, using sigmoidal dose-response curve fitting with variable slope.

DDR2 cell based assay

The inhibition of DDR2 phosphorylation by compounds was evaluated in HEK293T-DDR2 recombinant cells by phospho-ELISA assay. Briefly, HEK293T-DDR2 cells were seeded in poly-D-lysine-coated 24-well plates at a density of 250.000 cells/well and incubated for 1.5 hours at 37°C and 5% CO_2 in DMEM + 10% FBS. After that, the medium was changed to serum-free DMEM and cells were incubated for 3 hours. Then. test compounds were added at different concentrations 30 minutes before stimulation with bovine Type II Collagen at 50 µg/ml for further 3 hours. For DDR2 phospho-ELISA assay (DuoSet IC Human Phospho-DDR2; R&D Systems), protein extracts were obtained by adding 60 µl/well of lysis buffer prepared according to the manufacturer's instructions. Protein concentration in the samples was determined by BCA assay and the levels of phospho-DDR2 were determined following R&D Systems indications. Raw data were normalized to maximal inhibition control (0% for normalization) and positive control (100% for normalization; cells treated with 20 µg/ml collagen II) and IC50 parameters were calculated in GraphPad Prism 8.0 software, using sigmoidal dose-response curve fitting with variable slope.

The results for individual compounds are provided below in Table 5, wherein the compounds are classified in term of potency (nM) in binding and cell based assay with respect to their inhibitory activity on DDR1 and DDR2:

As it can be appreciated, the compounds of Table 5, i.e. the compounds of the invention, show a good activity as antagonist of DDR1 and DDR2. Accordingly, the compounds of the invention can be effectively used for treating disease, disorder or condition associated with DDR receptors, such as fibrosis, e.g. pulmonary fibrosis, idiopathic pulmonary fibrosis (IPF), hepatic fibrosis, renal fibrosis, ocular fibrosis, cardiac fibrosis, arterial fibrosis and systemic sclerosis.

Comparative Examples

Compounds of the Examples C1 and C2 were tested in the same binding assay described above.

Table 6

Example No	DDR1 Ki (nM)	DDR2 Ki (nM)
C1	238	172
C2	29000	50000

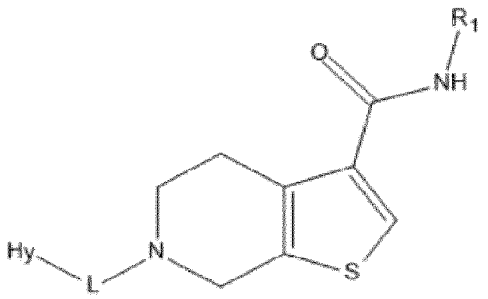

The compounds of the present invention, as shown in Table 5, have both a binding affinity for DDR1 and DDR2 receptors expressed as Ki and an inhibitory potency expressed as IC50 against DDR1 and DDR2 receptors lower than 80 nM, and for most of the compounds lower than 50 nM or even lower than 25 nM. Conversely, comparative Example C1 has a binding affinity higher than 230 nM on DDR1 receptor, and higher than 170 nM on DDR2; and comparative Example C2 has a binding affinity of 29000 nM on DDR1 receptor, and of 50000 nM on DDR2.

These data demonstrate that, conversely to the comparative compound of Example C1 characterized by lacking a linker between the tetrahydrothieno pyridine ring and Hy group, the presence in the compound of Example 2 of the present invention of a $-CH_2-$ linker in that position, unexpectedly and remarkably determines a relevant increase in the inhibitory activity on the DDR1 and DDR2 receptors.

As a further evidence, conversely to the compound of Example C2, characterized by the absence of a linker between the tetrahydrothieno pyridine ring and Hy group and by the -C(O)NH- group substitution at the α position with respect to sulphur atom, instead of the β position as in Example 2 of the present invention, the presence of the above mentioned linker concurrently with the substitution at the β position in the present invention compounds unexpectedly and noteworthy determines a relevant increase in the inhibitory activity against the DDR1 and DDR2 receptors.
