compounds and compositions which inhibit renin, processes for making such compounds, synthetic intermediates employed in these processes and a method of treating hypertension with such compounds.

Background Art

Renin is a proteolytic enzyme synthesized and stored principally in a specific part of the kidney called the juxtaglomerular apparatus. Any of three different physiologic circumstances may cause the release of renin into the circulation: (a) a decrease in the blood pressure entering or within the kidney itself; (b) a decrease in the blood volume in the body; or (c) a fall in the concentration of sodium in the distal tubules of the kidney.

When renin is released into the blood from the kidney, the renin-angiotensin system is activated, leading to vasoconstriction and conservation of sodium, both of which result in increased blood pressure. The renin acts on a circulating protein, angiotensinogen, to cleave out a fragment called angiotensin I (AI). AI

itself has only slight pharmacologic activity but, after additional cleavage by a second enzyme, angiotensin converting enzyme (ACE), forms the potent molecule angiotensin II (AII). The major pharmacological effects of AII are vasoconstriction and stimulation of the adrenal cortex to release aldosterone, a hormone which causes sodium retention. Sodium retention causes blood volume to increase, which leads to hypertension. AII is cleaved by an aminopeptidase to form angiotensin III (AIII), which, compared to AII, is a less potent vasoconstrictor but a more potent inducer of aldosterone release.

Inhibitors of renin have been sought as agents for control of hypertension and as diagnostic agents for identification of cases of hypertension due to renin excess.

With these objectives in mind, the renin-angiotensin system has been modulated or manipulated, in the past, with ACE inhibitors. However, ACE acts on several substrates other than angiotensin I (AI), most notably the kinins which cause such undesirable side effects as pain, "leaky" capillaries, prostaglandin release and a variety of behavioral and neurologic effects. Further, ACE inhibition leads to the accumulation of AI. Although AI has much less vasoconstrictor activity than AII, its presence may negate some of the hypotensive effects of the blockade of AII synthesis.

Inhibition of other targets in the renin-angiotensin system such as AII with compounds such as saralasin can block AII activity, but would leave unimpaired and perhaps enhance the hypertensive effects of AIII.

The compounds of the invention may be made as shown in Scheme 1, Scheme 2 and Scheme 3. Compound (IV) can serve as a common intermediate for the synthetic processes disclosed.

In particular, the process shown in Scheme 1 discloses an N-protected amino acid ester (I) which is reduced to the aldehyde and condensed with a vinyl anion equivalent to provide allylic alcohol (II) as an RS mixture at the hydroxyl center. Closure to the oxazolidone and isomer separation, followed by basic hydrolysis, affords the isomerically pure allylic alcohol (III). O- and N- protection of (III) yields (IV).

The process shown in Scheme 2 discloses bis-hydroxylation of allylic alcohol (IV) to provide a diol intermediate which is reacted with a diactivated carbonyl reagent to provide carbonate 11.

Alternatively, allylic alcohol (IV) may be epoxidized to (V) which is reacted with cyanide to give (VI) as an RS mixture at the free hydroxyl center. One isomer of (VI) is reduced to the free amine and then reacted with a diactivated carbonyl reagent to provide urethane 17. The other isomer of (VI) may also be reduced and the hydroxyl converted to an amine with inversion of stereochemistry. This amine is then reacted with a diactivated carboxyl reagent to provide urea 21. Epoxide (V) can also be reacted with monosubstituted amines to give intermediate amino-alcohols which are reacted with diactivated carbonyl reagents to provide urethanes 7, 8, 9, 28 and 104. The intermediate amino-alcohol can also be converted to a 1, 2-diamine via azide (VII). The 1, 2-diamine gives urea 14 after

reaction with a diactivated carbonyl reagent. Reaction of epoxide (V) with a 1-substituted - 2-protected hydrazine derivative provides intermediate (VIII), which is deprotected and reacted with a diactivated carbonyl reagent to provide urethane 24.

Heterocycles 7, 8, 9, 11, 14, 17, 21, 24, 28 and 104 are deprotected and coupled to peptide segments, which are described in Examples 30-103 or generally disclosed herein. (The peptide segments are either purchased commercially or are made by analogy to the examples disclosed herein). The coupling reaction is accomplished using either the mixed anhydride method (employing isobutyl chloroformate and N-methylmorpholine) or the carbodiimide method (employing N-ethyl-N'-(3-dimethylaminopropyl) carbodiimide, 1-hydroxybenzotriazole, and N-methylmorpholine in dimethylformamide) to give renin inhibitors of this invention. Deprotection of certain of these compounds yields still further renin inhibitors of this invention.

The process shown in Scheme 3 discloses the conversion of allylic alcohol (II) to aldehyde (IX) via a three step procedure comprising (a) oxazolidine formation using 2-methoxypropene and pyridinium p-toluenesulfonate, (b) ozonolysis, and (c) equilibration of diastereomers using potassium carbonate in methanol. Aldehyde (IX) is condensed with methyl 2-(bromomethyl)acrylate in the presence of zinc to give the unsaturated lactone (X). Hydrogenation of (X) over palladium on carbon leads to saturated lactone (XI). Reduction of (XI) with sodium borohydride gives diol (XII), which can be cyclized to the substituted

tetrahydrofuran (XIII) using a two step procedure including (a) mesylation with methanesulfonyl chloride and triethylamine and (b) ring closure with sodium hydride. Alternatively, (XI) can be alkylated using lithium diisopropylamide and an alkyl halide to provide (XIV). Reduction of (XIV) using sodium borohydride leads to diol (XV). Intermediates (X), (XI), (XII), (XIII), (XIV) and (XV) are deprotected and coupled to peptide segments in the manner disclosed in Scheme 2 to give the novel renin inhibiting compounds of this invention.

Ethyl hydrogen (α,α -dimethylbenzyl)malonate.

Diethyl (α,α -dimethylbenzyl)malonate was prepared by the conjugate addition of phenyl magnesium bromide to diethyl isopropylidenemalonate as described by C. Holmberg [Liebigs Ann. Chem., 748 (1981)]. A solution of this diester (42.1 g, 0.15 mmol) in ethanol (100 ml) was treated by dropwise addition with a solution of potassium hydroxide (8.48 g, 0.13 mmol) in 100 ml of ethanol. After heating at 90°C for 1 h and at 50°C for 20 h, the reaction mixture was evaporated on the rotary evaporator to a residue. The residue was diluted with water and extracted with ether to remove unreacted starting material. The aqueous phase was cooled to 5°C, acidified to pH 3 with 6N HCl, and extracted with methylene chloride. The organic layer was washed with brine solution and dried over magnesium sulfate. Evaporation of the solvent gave 27.3 g (84%) of liquid product. 1HMR ($CDCl_3$): 1.05 (t, 3H), 1.6 (s, 6H), 3.78 (s, 1H), 3.96 (m, 2H), 7.2-7.4 (m, 5H).

The compounds of the present invention can be used in the form of salts derived from inorganic or organic acids. These salts include but are not limited to the following: acetate, adipate, alginate, citrate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, camphorate, camphorsulfonate, digluconate, cyclopentanepropionate, dodecylsulfate, ethanesulfonate, glucoheptonate, glycerophosphate, hemisulfate, heptonate, hexanoate, fumarate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxy-ethanesulfonate, lactate, maleate, methanesulfonate, nicotinate, 2-naphthalenesulfonate, oxalate, pamoate, pectinate, persulfate, 3-phenylpropionate, picrate, pivalate, propionate, succinate, tartrate, thiocyanate, tosylate, and undecanoate. Also, the basic nitrogen-containing groups can be quaternized with such agents as loweralkyl halides, such as methyl, ethyl, propyl, and butyl chloride, bromides, and iodides; dialkyl sulfates like dimethyl, diethyl, dibutyl, and diamyl sulfates, long chain halides such as decyl, lauryl, myristyl and stearyl chlorides, bromides and iodides, aralkyl halides like benzyl and phenethyl bromides, and others. Water or oil-soluble or dispersible products are thereby obtained.

Examples of acids which may be employed to form pharmaceutically acceptable acid addition salts include such inorganic acids as hydrochloric acid, sulphuric acid and phosphoric acid and such organic acids as oxalic acid, maleic acid, succinic acid and citric acid. Other salts include salts with alkali metals or alkaline earth metals, such as sodium, potassium, calcium or magnesium or with organic bases.

The compounds of the present invention can also be used in the form of esters. Examples of such esters include a hydroxyl-substituted compound of formula I which has been acylated with a blocked or unblocked amino acid residue, a phosphate function, or a hemisuccinate residue. The amino acid esters of particular interest are glycine and lysine; however, other amino acid residues can also be used. These esters serve as pro-drugs of the compounds of the present invention and serve to increase the solubility of these substances in the gastrointestinal tract. The preparation of the pro-drug esters is carried out by reacting a hydroxyl-substituted compound of formula I with an activated amino acyl, phosphoryl or hemisuccinyl derivative. The resulting product is then deprotected to provide the desired pro-drug ester.

The novel compounds of the present invention possess an excellent degree of activity and specificity in treating hypertension in a host. The ability of the compounds of the invention to inhibit human renal renin can be demonstrated in vitro by reacting a selected compound at varied concentrations with human renal renin, free from acid proteolytic activity, and with renin substrate (human angiotensinogen) at 37 degrees C and pH of 6.0. At the end of the incubation, the amount of angiotensin I formed is measured by radioimmunoassay and the molar concentration required to cause 50% inhibition, expressed as the IC_{50} , is calculated. When tested in accordance with the foregoing procedure, the compounds of the invention demonstrated IC_{50} 's in the range of 10^{-6} to 10^{-10} M as seen in Table I.

The compounds of the invention may also be used with one or more antihypertensive agents selected from the group consisting of diuretics, and/or β -adrenergic blocking agents, central nervous system-acting agents, adrenergic neuron blocking agents, vasodilators, angiotensin I converting enzyme inhibitors, and other antihypertensive agents.

Total daily dose administered to a host in single or divided doses may be in amounts, for example,

from 0.001 to 10 mg/kg body weight daily and more usually 0.01 to 10 mg. Dosage unit compositions may contain such amounts of submultiples thereof to make up the daily dose.

The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration.

It will be understood, however, that the specific dose level for any particular patient will depend upon a variety of factors including the activity of the specific compound employed, the age, body weight, general health, sex, diet, time of administration, route of administration, rate of excretion, drug combination, and the severity of the particular disease undergoing therapy.

The compounds of the present invention may be administered orally, parenterally, by inhalation spray, rectally, or topically in dosage unit formulations containing conventional nontoxic pharmaceutically acceptable carriers, adjuvants, and vehicles as desired. Topical administration may also involve the use of transdermal administration such as transdermal patches or iontophoresis devices. The term parenteral as used herein includes subcutaneous injections, intravenous, intramuscular, intrasternal injection, or infusion techniques.

Injectable preparations, for example, sterile injectable aqueous or oleagenous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile

injectable solution or suspension in a nontoxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable nonirritating excipient such as cocoa butter and polyethylene glycols which are solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum and release the drug.

Solid dosage forms for oral administration may include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound may be admixed with at least one inert diluent such as sucrose lactose or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than inert diluents, e.g., lubricating agents such as magnesium stearate. In the case of capsules, tablets, and pills, the dosage forms may also comprise buffering agents. Tablets and pills can additionally be prepared with enteric coatings.

Liquid dosage forms for oral administration may include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs containing inert diluents commonly used in the art, such as water.

-162-

Such compositions may also comprise adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring, and perfuming agents.

The foregoing is merely illustrative of the invention and is not intended to limit the invention to the disclosed compounds. Variations and changes which are obvious to one skilled in the art are intended to be within the scope and nature of the invention which are defined in the appended claims.
