## **QUINOLONES AND AZAQUINOLONES THAT INHIBIT PROLYL HYDROXYLASE**

### **FIELD OF THE INVENTION**

[002] The present invention relates to compounds capable of inhibiting prolyl hydroxylases such as HIF prolyl hydroxylases, compounds that modulate HIF levels, compounds that stabilize HIF, compositions comprising the compounds, and methods for their use for controlling HIF levels. The compounds and compositions may be used to treat diseases or conditions modulated by HIF such as ischemia, anemia, wound healing, auto-transplantation, allo-transplantation, xeno-transplantation, systemic high blood pressure, thalassemia, diabetes, cancer, and inflammatory disorders.

### **BACKGROUND OF THE INVENTION**

[003] The cellular transcription factor HIF (Hypoxia Inducible Factor) occupies a central position in oxygen homeostasis in a wide range of organisms and is a key regulator of responses to hypoxia. The genes regulated by HIF transcriptional activity can play critical roles in angiogenesis, erythropoiesis, hemoglobin F production, energy metabolism, inflammation, vasomotor function, apoptosis and cellular proliferation. HIF can also play a role in cancer, in which it is commonly upregulated, and in the pathophysiological responses to ischemia and hypoxia.

[004] The HIF transcriptional complex comprises an  $\alpha\beta$  heterodimer: HIF- $\beta$  is a constitutive nuclear protein that dimerizes with oxygen-regulated HIF- $\alpha$  subunits. Oxygen regulation occurs through hydroxylation of the HIF- $\alpha$

subunits, which are then rapidly destroyed by the proteasome. In oxygenated cells, the von Hippel-Lindau tumor suppressor protein (pVHL) binds to hydroxylated HIF- $\alpha$  subunits, thereby promoting their ubiquitin dependent proteolysis. This process is suppressed under hypoxic conditions, stabilizing HIF- $\alpha$  and promoting transcriptional activation by the HIF  $\alpha\beta$  complex. *See, e.g.*, U.S. Patent 6,787,326.

[005] Hydroxylation of HIF- $\alpha$  subunits can occur on proline and asparagine residues and can be mediated by a family of 2-oxoglutarate dependent enzymes. This family includes the HIF prolyl hydroxylase isozymes (PHDs), which hydroxylate Pro 402 and Pro 564 of human HIF1 $\alpha$ , as well as Factor Inhibiting HIF (FIH), which hydroxylates Asn 803 of human HIF1 $\alpha$ . Inhibition of FIH or the PHDs leads to HIF stabilization and transcriptional activation. *See, e.g.*, Schofield and Ratcliffe, *Nature Rev. Mol. Cell Biol.*, Vol 5, pages 343-354 (2004).

#### **DETAILED DESCRIPTION OF THE INVENTION**

[054] Unless otherwise indicated, all numbers expressing quantities of ingredients, reaction conditions, and so forth used in the specification and claims are to be understood as being modified in all instances by the term “about.” Accordingly, unless indicated to the contrary, the numerical parameters set forth in the following specification and attached claims are approximations that may vary depending upon the standard deviation found in their respective testing measurements.

[055] As used herein, if any variable occurs more than one time in a chemical formula, its definition on each occurrence is independent of its definition at every other occurrence. If the chemical structure and chemical name conflict, the chemical structure is determinative of the identity of the compound. The compounds of the present disclosure may contain one or more chiral centers and/or double bonds and therefore, may exist as stereoisomers, such as double-bond isomers (i.e., geometric isomers), enantiomers or diastereomers. Accordingly, any chemical structures within the scope of the specification depicted, in whole or in part, with a relative configuration encompass all possible enantiomers and stereoisomers of the illustrated compounds including the stereoisomerically pure form (e.g., geometrically pure, enantiomerically pure or diastereomerically pure) and enantiomeric and stereoisomeric mixtures. Enantiomeric and stereoisomeric mixtures can be resolved into the component enantiomers or stereoisomers using separation techniques or chiral synthesis techniques well known to the skilled artisan.

[056] Compounds of Formula I include, but are not limited to, optical isomers of compounds of Formula I, racemates, and other mixtures thereof. In

those situations, the single enantiomers or diastereomers, i.e., optically active forms, can be obtained by asymmetric synthesis or by resolution of the racemates. Resolution of the racemates can be accomplished, for example, by conventional methods such as crystallization in the presence of a resolving agent, or chromatography, using, for example a chiral high-pressure liquid chromatography (HPLC) column. In addition, compounds of Formula I include Z- and E- forms (or *cis*- and *trans*- forms) of compounds with double bonds.

[057] Compounds of the invention may exist in multiple tautomeric forms. These forms are illustrated below as “Tautomer A”, “Tautomer B”, and “Tautomer C”:

Compounds of the invention are depicted structurally and named as compounds in the “Tautomer A” form. [0140] The term “composition” as used herein is intended to encompass a product comprising the specified ingredients (and in the specified amounts, if indicated), as well as any product which results, directly or indirectly, from combination of the specified ingredients in the specified amounts. By “pharmaceutically acceptable” it is meant that the carrier, excipient, or diluent is compatible with the other ingredients of the formulation and is not deleterious to the recipient thereof.

[0141] Composition formulation may improve one or more pharmacokinetic properties (*e.g.*, oral bioavailability, membrane permeability) of a compound of the invention (herein referred to as the active ingredient).

[0142] The pharmaceutical compositions for the administration of the compounds of this invention may conveniently be presented in unit dosage form and may be prepared by any of the methods well known in the art. All methods include the step of bringing the active ingredient into association with the carrier which constitutes one or more accessory ingredients. In general, the pharmaceutical compositions are prepared by uniformly and intimately bringing the active ingredient into association with a liquid carrier or a finely divided solid carrier or both, and then, if necessary, shaping the product into the desired formulation. In the pharmaceutical composition, the active object compound is included in an amount sufficient to produce the desired effect upon the process or condition of diseases.

[0143] The pharmaceutical compositions containing the active ingredient may be in a form suitable for oral use, for example, as tablets, troches, lozenges, aqueous or oily suspensions, dispersible powders or granules, emulsions, hard or soft capsules, or syrups or elixirs. Compositions intended for oral use may be prepared according to any method known to the art for the manufacture of pharmaceutical compositions. Such compositions may contain one or more agents selected from sweetening agents, flavoring agents, coloring agents and preserving agents in order to provide pharmaceutically elegant and palatable preparations. Tablets contain the active ingredient in admixture with other non-toxic pharmaceutically acceptable excipients which are suitable for the manufacture of tablets. These excipients may be, for example, inert diluents, such as calcium carbonate, sodium carbonate, lactose, calcium phosphate or sodium phosphate; granulating and disintegrating agents, for example, corn starch, or alginic acid; binding agents, for example starch, gelatin or acacia, and lubricating agents, for example magnesium stearate, stearic acid, or talc. The tablets may be uncoated or they may be coated by known techniques to delay disintegration and absorption in the gastrointestinal tract and thereby provide a sustained action over a longer period. For example, a time delay material such as glyceryl monostearate or glyceryl distearate may be employed. They may also be coated by the techniques described in U.S. Patent Nos. 4,256,108, 4,160,452, and 4,265,874 to form osmotic therapeutic tablets for control release.

[0144] Formulations for oral use may also be presented as hard gelatin capsules wherein the active ingredient is mixed with an inert solid diluent, for example, calcium carbonate, calcium phosphate, or kaolin, or as soft gelatin capsules wherein the active ingredient is mixed with water or an oil medium, for example peanut oil, liquid paraffin, or olive oil.

[0145] Aqueous suspensions contain the active materials in admixture with excipients suitable for the manufacture of aqueous suspensions. Such excipients are suspending agents, for example sodium carboxymethylcellulose, methylcellulose, hydroxy-propylmethylcellulose, sodium alginate, polyvinylpyrrolidone, gum tragacanth and gum acacia; dispersing or wetting agents may

be a naturally-occurring phosphatide, for example lecithin, or condensation products of an alkylene oxide with fatty acids, for example polyoxy-ethylene stearate, or condensation products of ethylene oxide with long chain aliphatic alcohols, for example heptadecaethyleneoxycetanol, or condensation products of ethylene oxide with partial esters derived from fatty acids and a hexitol such as polyoxyethylene sorbitol monooleate, or condensation products of ethylene oxide with partial esters derived from fatty acids and hexitol anhydrides, for example polyethylene sorbitan monooleate. The aqueous suspensions may also contain one or more preservatives, for example ethyl, or n-propyl, p-hydroxybenzoate, one or more coloring agents, one or more flavoring agents, and one or more sweetening agents, such as sucrose or saccharin.

[0146] Oily suspensions may be formulated by suspending the active ingredient in a vegetable oil, for example arachis oil, olive oil, sesame oil, or coconut oil, or in a mineral oil such as liquid paraffin. The oily suspensions may contain a thickening agent, for example beeswax, hard paraffin, or cetyl alcohol. Sweetening agents such as those set forth above, and flavoring agents may be added to provide a palatable oral preparation. These compositions may be preserved by the addition of an anti-oxidant such as ascorbic acid.

[0147] Dispersible powders and granules suitable for preparation of an aqueous suspension by the addition of water provide the active ingredient in admixture with a dispersing or wetting agent, suspending agent and one or more preservatives. Suitable dispersing or wetting agents and suspending agents are exemplified by those already mentioned above. Additional excipients, for example sweetening, flavoring and coloring agents, may also be present.

[0148] The pharmaceutical compositions of the invention may also be in the form of oil-in-water emulsions. The oily phase may be a vegetable oil, for example olive oil or arachis oil, or a mineral oil, for example liquid paraffin or mixtures of these. Suitable emulsifying agents may be naturally-occurring gums, for example gum acacia or gum tragacanth, naturally-occurring phosphatides, for example soy bean, lecithin, and esters or partial esters derived from fatty acids and hexitol anhydrides, for example sorbitan monooleate, and

condensation products of the said partial esters with ethylene oxide, for example polyoxyethylene sorbitan monooleate. The emulsions may also contain sweetening and flavoring agents.

[0149] Syrups and elixirs may be formulated with sweetening agents, for example glycerol, propylene glycol, sorbitol or sucrose. Such formulations may also contain a demulcent, a preservative, and flavoring and coloring agents.

[0150] The pharmaceutical compositions may be in the form of a sterile injectable aqueous or oleagenous suspension. This suspension may be formulated according to the known art using those suitable dispersing or wetting agents and suspending agents which have been mentioned above. The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example as a solution in 1,3-butane diol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose, any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

[0151] The pharmaceutical compositions may also be administered in the form of suppositories for rectal administration of the drug. These compositions can be prepared by mixing the drug with a suitable non-irritating excipient which is solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum to release the drug. Such materials include, for example, cocoa butter and polyethylene glycols.

[0152] For topical use, creams, ointments, jellies, solutions, or suspensions, *etc.*, containing the compounds of the invention are employed. As used herein, topical application is also meant to include the use of mouthwashes and gargles.

[0153] The compounds of the invention can be prepared using the general synthetic routes shown below in Scheme 1 and Scheme 2 and described more fully in the Examples.

**Scheme 1****Scheme 2**

[0154] Synthetic intermediates used to prepare the compounds of the invention can be synthesized by the methodology shown in Scheme 3 and described more fully in the Examples.

**Scheme 3**

[0242] The following are examples of methods that may be used to quantitate HIF PHD activity and the inhibition of HIF PHD activity by compounds of the present invention.

Expression, Purification and Europium Labeling of VCB and Design of an Eu-VCB based TR-FRET Assay for the Detection of Hydroxyprolyl HIF1 $\alpha$  Peptides

[0243] The VCB complex is defined as the Von Hippel-Lindau protein (pVHL), elongin B and elongin C heterotrimeric complex. VCB specifically binds to hydroxyproline residues of HIF1 $\alpha$ , initiating polyubiquitinylation of HIF1 $\alpha$  and its subsequent proteolytic destruction. In the absence of prolyl hydroxylase activity, VCB does not bind unmodified HIF1 $\alpha$ . The VCB complex was expressed in *E.coli* and purified from the soluble fraction. The amino acid sequences of the three protein components are as follows:

The N-terminus of VHL contains a six histidine affinity tag for purification purposes.

[0244] A VCB-based assay allows a highly sensitive and direct measurement of enzymatic product formation (HIF1 $\alpha$  protein or fragments thereof containing a hydroxylated proline residue) and is suitable for high throughput screening.

[0245] For expression in *E.coli*, VHL 54-213 was cloned into pAMG21 (Plux promoter) between the NdeI-XhoI site. Immediately downstream of this is the ElonginC gene cloned into the XhoI site to SacII. There is a 13 bp spacer between the stop codon of VHL and the initiating codon of ElonginC. The expression plasmid pAMG21 is a 6118 base pair plasmid that was derived from the expression vector pCFM1656 (ATCC #69576), which in turn can be derived from the expression vector system described in US Patent No. 4,710,473. This design allows for chemical rather than thermal induction of protein expression by substitution of the promoter region, replacing a synthetic bacteriophage lambda pl promoter with a DNA segment containing the LuxR gene and the LuxPR promoter, and affords regulation of expression by the plasmid-encoded LuxR protein, thereby allowing any *E.coli* strain to serve as host.

[0246] ElonginB was cloned into pTA2 (pACYC184.1 based vector) under the control of a Lac promoter. Competent *E.coli* cells were transformed with the pAMG21-VHL-ElonginC construct. These *E.coli* cells were rendered competent again prior to transformation with the pTA2-elonginB construct to produce the final *E.coli* strain containing both plasmid constructs. Induction of

protein expression was initiated by the addition of IPTG and N-(3-oxo-hexanoyl)-homoserine lactone (HSL) at 30°C.

[0247] Bacterial cells were lysed by a microfluidizer in aqueous buffer of pH 8.0 and the soluble fraction was separated by centrifugation. The soluble *E.coli* fraction was subjected to Nickel-NTA chelating chromatography to utilize the six histidine affinity tag located on the pVHL construct. The pooled fractions from the nickel column were applied to a Superdex 200 size exclusion<sup>\*</sup> chromatography (SEC) column. The protein eluted as a monomer on SEC, indicating that the three protein components formed a complex in solution. The fractions from the SEC column were pooled and applied to a Q Sepharose anion exchange column for final purification. The purified complex was visualized by SDS-PAGE and the identities of the three protein components were confirmed by N-terminal amino acid sequencing.

[0248] Purified VCB was exchanged into 50 mM sodium carbonate buffer pH 9.2 and labeled with a europium chelate overnight. LANCE<sup>TM</sup> europium chelate (PerkinElmer, Inc; Eu-W1024 ITC chelate; catalog number is AD0013) was used to label the lysine residues of the VCB complex. The chelate contains an isothiocyanate reactive group that specifically labels proteins on lysine residues (there are fifteen lysine residues in the VCB protein complex). The resulting europylated VCB was purified by desalting columns and quantitated by standard means. The labeling yield was determined to be 6.6 europium groups per one VCB complex.

[0249] Two peptides were produced by SynPep, Inc.: a hydroxyproline modified peptide and an unmodified control peptide. VCB was expected to specifically bind to the hydroxyproline modified peptide (a mimic of enzymatic hydroxylation by prolyl hydroxylase). VCB was not expected to bind to the unmodified peptide. Both peptides were produced with a biotin group at the N-terminus to allow for binding by the streptavidin-labeled fluorescent acceptor allophycocyanin (streptavidin APC; Prozyme, Inc.).

[0250] The sequence of the custom synthesized HIF1 $\alpha$  peptides (amino acids 556-575, with methionine residues replaced with alanine residues to prevent oxidation) were as follows:

(unmodified) Biotin-DLDLEALAPYIPADDDFQLR-CONH<sub>2</sub> (SEQ ID NO: 4)

(modified) Biotin-DLDLEALA[hyP]YIPADDDFQLR-CONH<sub>2</sub> (SEQ ID NO: 5)

[0251] The peptides were purchased from SynPep as lyophilized solids and were suspended in DMSO for experimental use. The peptides were quantitated according to their absorbance at 280 nm.

[0252] Experiments were conducted in 96 well Costar polystyrene plates. Biotinylated peptides and europylated VCB were suspended in the following buffer: 100 mM HEPES 7.5, 0.1 M NaCl, 0.1% BSA and 0.05% Tween<sup>\*</sup> 20. The reagents were allowed to reach equilibrium by shaking for 1 hour before the plates were read on the Discovery Instrument (Packard). The data output is the ratio of the 665 nm and 620 nm emission signal resulting from the 320 nm excitation.

[0253] As shown in Figure 1, the specific interaction of europylated VCB with the hydroxyproline modified HIF1 $\alpha$  peptide coupled to streptavidin APC generated a fluorescence signal detectable over the background signal. These results demonstrate a fluorescence signal generated by the specific interaction of Eu-VCB with hyp-HIF1 $\alpha$  peptide. Each bar represents the data from a single well of a 96 well assay plate. The signal to background ratio was calculated from data from a control plate (unmodified peptide). Eu-VCB concentration was titrated across rows (nM) and streptavidin APC concentrations were titrated down columns. The peptide concentration was fixed at 100 nM.

Detection of Enzymatically Converted Hydroxyprolyl HIF-1 $\alpha$  by  
HIF PHD2 and Inhibition of HIF PHD2 activity

[0254] Binding of the P564-HIF1 $\alpha$  peptide to VCB was validated utilizing the homogeneous time-resolved FRET (TR-FRET) technology. A 17 amino acid (17aa) peptide with an N-terminally labeled biotin molecule corresponding to amino acid sequences 558 to 574 of the HIF1 $\alpha$  protein was

synthesized in-house (DLEMLAPYIPMDDDFQL (SEQ ID NO: 6)). A second 17aa peptide containing a hydroxylated proline at position 564 was chemically generated to mimic the PHD enzyme converted product form of the protein that is recognized by VCB. The assay was performed in a final volume of 100  $\mu$ L in buffer containing 50 mM Tris-HCl (pH 8), 100 mM NaCl, 0.05% heat inactivated FBS, 0.05% Tween-20, and 0.5%  $\text{NaN}_3$ . The optimal signal over background and the linear range of detection was determined by titrating the hydroxylated or unhydroxylated peptide at varied concentrations between 0 and 1  $\mu$ M with a titration of VCB-Eu at varying concentrations between 0 and 50 nM with 50 nM of streptavidin APC. The binding reagents were allowed to reach equilibrium by shaking for 1 hour before it was read on the Discovery Instrument (Packard). The data output is the ratio of the 665 nm and 620 nm emission signal resulting from the 320 nm excitation.

[0255] HIF PHD2 activity was detected by P564-HIF1 $\alpha$  peptide and VCB binding in the TR-FRET format. HIF PHD2 was assayed at various concentrations between 0 and 400nM with 3  $\mu$ M HIF1 $\alpha$  peptide in buffer containing 50 mM Tris-HCl (pH 7.5), 100 mM NaCl, 0.05% Tween 20, 2 mM 2-oxoglutarate (2-OG), 2 mM ascorbic acid and 100  $\mu$ M  $\text{FeCl}_2$  in a final volume of 100  $\mu$ L. The time-course was determined by periodically transferring 2.5  $\mu$ L of the reaction into 250  $\mu$ L of 10x TR-FRET buffer containing 500 mM HEPES (pH 7.5), 1 M NaCl, 1% BSA, and 0.5% Tween-20 to terminate the enzyme reaction. 15nM HIF-1 $\alpha$  peptide from the terminated reaction was added to 35 nM streptavidin-APC and 10nM VCB-Eu to a final volume of 100  $\mu$ L in 10X TR-FRET buffer. The TR-FRET reagents were placed on a shaker for 1 hour before detection on the Discovery platform.

[0256] As demonstrated in Figures 2A and 2B, there was a dose dependent increase in TR-FRET signal resulting from binding of the hydroxylated-P564-HIF1 $\alpha$  peptide to VCB-Eu compared to the unhydroxylated form of the peptide resulting in a 14 fold signal over noise ratio at 125 nM HIF1 $\alpha$  peptide. VCB binding to the APC bound peptide permits a FRET transfer between the Eu and APC. The signal was linear to 2 nM peptide with 3.125 nM

VCB, but increases to 62.5 nM peptide with 50 nM VCB resulting in a larger linear range.

[0257] TR-FRET detection utilizing Eu-labeled VCB is a practical system for determining HIF PHD2 catalytic activity. HIF PHD2 hydroxylation of the HIF1 $\alpha$  peptide results in the increase affinity of VCB to the peptide and hence and increased FRET signal. As shown in Figures 3A and 3B, activity was verified with a fairly linear and an increasing TR-FRET signal over time. There was a dose dependant increase in initial rates with increasing HIF PHD2 enzyme concentration up to 400 nM. The initial rates were linear to 100 nM enzyme.

[0258] Inhibition of HIF PHD2 activity was quantified utilizing the TR-FRET technology. HIF PHD2 catalyzes a hydroxyl modification on the proline residue of the P564-HIF1 $\alpha$  peptide substrate (Biotin-DLEMLAPYIPMDDDFQL (SEQ ID NO: 7)) resulting in recognition and binding of the europylated Von Hippel-Lindau protein (pVHL), elongin B and elongin C heterotrimeric (VCB-Eu) complex.

[0259] The PHD2 inhibition assay was executed by addition of freshly dissolved FeCl<sub>2</sub> to 178.57  $\mu$ M (100  $\mu$ M final concentration) in PHD2 Reaction Buffer containing 30 mM MES, pH 6, 10 mM NaCl, 0.25% Brij-35, 0.01% BSA, and 1% DMSO. 28  $\mu$ L of the iron solution and 2  $\mu$ L of inhibitor compounds serially diluted in 100% DMSO (5% DMSO final) were added to black polypropylene 96-well microtiter plates. To that, 10  $\mu$ L of 10 nM PHD2 (2 nM final) was added to all wells of the plate except for the 8 wells of column 12 (LO control), and allowed to incubate at room temperature on the shaker for one hour. Column 6 was the HI control containing PHD2 enzyme and 5% DMSO vehicle, but no inhibitor compound. To initiate the PHD2 enzymatic reaction, 10  $\mu$ L of a solution containing 500 nM P564-HIF1 $\alpha$  peptide (100 nM final), 10 mM ascorbic acid (2 mM final), and 1.25  $\mu$ M 2-oxoglutarate ( $\alpha$ -ketoglutarate; 0.25  $\mu$ M final) in PHD2 Reaction Buffer was added to all wells of the plate and allowed to incubate on the shaker at room temperature for one hour.

[0260] The reaction was terminated by addition of 25  $\mu$ L TR-FRET Buffer (50 mM TRIS-HCl, pH 9, 100 mM NaCl, 0.05% BSA, and 0.5% Tween-20)

containing 150 mM succinate (product inhibitor; 50 mM final), 75 nM streptavidin-APC (25 nM final), and 7.5 nM VCB-Eu (2.5 nM final). The TR-FRET detection reagents were placed on a shaker for 1 hour to reach binding equilibrium before reading on the Discovery platform (PerkinElmer). Europium is excited at 315 nm and phosphoresces at 615nm with a large Stoke's shift. APC, in turn, emits at 655 nm upon excitation at 615 nm. The TR-FRET signal is measured as the ratio of the APC 655 nm signal divided by the internal europium reference 615 nm emission signal.

[0261] The POC (percentage of control) was determined by comparing the signal from hydroxylated peptide substrate in the enzyme reaction containing inhibitor compound with that from PHD2 enzyme with DMSO vehicle alone (HI control), and no enzyme (LO control). POC was calculated using the formula: % control (POC) = (cpd – average LO) / (average HI – average LO)\*100. Data (consisting of POC and inhibitor concentration in  $\mu\text{M}$ ) was fitted to a 4-parameter equation ( $y = A + ((B-A) / (1 + ((x/C)^D)))$ ), where A is the minimum y (POC) value, B is the maximum y (POC), C is the x (cpd concentration) at the point of inflection and D is the slope factor) using a Levenburg-Marquardt non-linear regression algorithm.

[0262] In certain embodiments, compounds of the present invention exhibit a HIF PHD inhibitory activity  $\text{IC}_{50}$  value of 40  $\mu\text{M}$  or less. In additional embodiments, compounds of the present invention exhibit a HIF PHD inhibitory activity  $\text{IC}_{50}$  value of 10  $\mu\text{M}$  or less and in further embodiments, compounds of the present invention exhibit a HIP PHD inhibitory activity  $\text{IC}_{50}$  value of 5  $\mu\text{M}$  or less.

Collagen Prolyl Hydroxylase I and II Activity Determined by Radiometric HPLC  
Measurement of 2-Oxoglutarate Conversion to Succinic Acid

[0264] IC<sub>50</sub> values were obtained for the Example compounds with respect to Collagen Prolyl Hydroxylase I (CPH1) and Collagen Prolyl Hydroxylase II (CPH2) using the assay methods described below. Surprisingly, replacement of an amide N in the side chain of the molecule with a C atom greatly enhanced the selectivity of the Example compounds for PHD2 with respect to CPH1 and CPH2.

[0265] Assay conditions were established in separate studies to define dependence on dithiothreitol (DTT), ascorbate, and catalase, and to define reaction linearity and K<sub>m</sub> values for 2-oxoglutarate (2-OG; PerkinElmer LAS, Shelton, CT or Moravek Biochemicals, Brea, CA), FeSO<sub>4</sub>, and (Pro-Pro-Gly)<sub>10</sub> peptide (PPG<sub>10</sub>; Peptides International, Louisville, KY). Linearity was evident

to at least 40% conversion but reactions did not typically exceed 30% conversion of 2-OG to succinic acid (SA). Product inhibition was not evident. Compounds were dissolved and serially diluted in 100% DMSO for potency determination. Assay Buffer consisted of Tris-HCl, pH 7.5, 0.2 mM DTT, and 0.5 mg/ml catalase. PPG<sub>10</sub> peptide was dissolved in 0.25% acetic acid and denatured by boiling for 5 minutes then placed on ice for 5 minutes. The denatured PPG<sub>10</sub> was then pre-mixed with 1 M ascorbate, prepared in water, and the mixture diluted with Assay Buffer to yield a working solution of 5X peptide and ascorbate. FeSO<sub>4</sub> was freshly dissolved in water and diluted to a 2.8X concentration in Assay Buffer. Enzyme stocks were diluted to a 5X concentration in Assay Buffer. Example compounds plus FeSO<sub>4</sub> solution were mixed, followed by addition of 5X enzyme solutions. After 10 minutes gentle mixing at room temperature, the 5X peptide solution was added. After another 10 minutes gentle mixing at room temperature, a 5X stock of 2-OG was added to initiate the reaction. Final concentrations in the assay were: 50 mM Tris-HCl, pH 7.5, 0.2 mM DTT, 0.5 mg/mL catalase, 10  $\mu$ M FeSO<sub>4</sub>, 100  $\mu$ M PPG<sub>10</sub>, 50  $\mu$ M 5-[<sup>14</sup>C]-2-oxoglutarate (23-37 cpm/pmol), 1 mM ascorbate, and 4% DMSO. Reactions were gently mixed at room temperature for 1 hour and terminated by addition of an equal volume of 0.02 N H<sub>2</sub>SO<sub>4</sub>. Unless otherwise indicated, all reagents were obtained from Sigma and were the highest grade available.

[0266] A portion of each terminated reaction was auto-injected into a Polypore H column (PerkinElmer, Waltham, MA) at a rate of 0.3 mL/min with 0.01 N H<sub>2</sub>SO<sub>4</sub> as the mobile phase. The HPLC method employed exploits the difference in pK<sub>a</sub> of the 2-OG and SA carboxylates to chromatographically separate substrate from product at low pH on ion-exchange resin, as described by Cunliffe, et al (Biochem J., **240**, 617-619 (1986)) and Kaule and Gunzler (Anal. Biochem., **184**, 291-297 (1990)). An Agilent 1100 HPLC System with dual quaternary pumps, column switching valve, and dual columns was used to resolve product from substrate. The Agilent 1100 Multiple Wavelength Detector indicated UV absorption of the substrate and product peaks at 210 nm

and a Beta-RAM Model 2 radiation detector with In-Flow 2:1 scintillation cocktail (IN/US Systems Inc.) enabled quantitation of the 2 radioactive peaks. Laura Lite<sup>\*</sup> software (IN/US, Tampa, FL) was used to collect and analyze radiometric data. AUC measurements were converted to percent turnover of 2-OG. To standardize across studies, 2-OG conversion was normalized to percent of control (POC) values using reactions that lacked enzyme or inhibitor as low and high controls, respectively. POC data was fitted to the 4-parameter logistic model  $(A + ((B - A) / (1 + ((x / C)^D))))$  using ActivityBase<sup>\*</sup> (IDBS, Alameda CA) where A is the minimum POC value, B is the maximum POC value, D is the slope factor, and C is compound concentration at the inflection point (IC<sub>50</sub>, micromolar).

#### Cloning and Expression of CPH1 and CPH2 Enzymes

[0267] The Baculovirus Expression Vector System (BEVS) from Invitrogen was used to express collagen prolyl 4-hydroxylase (CPH) in *Trichoplusia ni* insect cells. Active collagen prolyl 4-hydroxylase is an oligomeric protein that exists as an  $\alpha_2\beta_2$  tetramer. The alpha subunits incorporated into the tetramer can be either collagen prolyl 4-hydroxylase  $\alpha_1$  (GenBank reference sequence NM\_000917) or collagen prolyl 4-hydroxylase  $\alpha_2$  (GenBank reference sequence NM\_004199). The beta subunit, collagen prolyl 4-hydroxylase  $\beta$  (GenBank reference sequence NM\_000918), is common to both forms of the tetramer. The genes encoding the three subunits,  $\alpha_1$ ,  $\alpha_2$  and  $\beta$ , were cloned individually into separate pFastBac1<sup>\*</sup> shuttle vectors (Invitrogen) in their precursor forms, which include the native human secretion signal sequences. For the purpose of identifying expressed protein, the  $\alpha$  subunit genes included a caspase-3 cleavable six-histidine metal affinity sequence at the 5' end of the gene. In the expressed protein, the metal affinity tag (MAHHHHHHDEVD)(SEQ ID NO: 8) was positioned at the  $\alpha$  subunit N-terminus upstream of the secretion signal sequence. For the purpose of identification and purification, the  $\beta$  subunit gene was designed to encode a six-histidine metal affinity tag positioned downstream of the secretion signal

peptide so that the metal affinity tag would remain after cleavage and secretion into the endoplasmic reticulum. These recombinant pFastBac1 shuttle vectors were each used to generate baculovirus capable of expressing their respective subunit polypeptides. The active, tetrameric form of the enzyme was generated by co-expressing either CPH- $\alpha$ 1 and CPH- $\beta$  or CPH- $\alpha$ 2 and CPH- $\beta$  baculovirus at 27°C. Cells were harvested 48 hours post-infection by centrifugation.

#### Purification and Characterization of CPH Enzymes

[0269] *T.ni* cells were resuspended in 25 mM Tris (pH 7.8), 0.15M NaCl, 10% glycerol, 0.1% Triton X-100, and Complete “Free” protease inhibitor cocktail (Roche) and were lysed by a microfluidizer. Lysate was cleared by centrifugation and filtered through a 0.45  $\mu$ m cellulose acetate membrane before application to a Ni-NTA column at 2mL/min. The column was washed with 25 mM imidazole and protein was eluted with a buffer containing; 20 mM Tris 7.8, 0.15 M NaCl, 10% glycerol, 0.1% CHAPS and 250 mM imidazole. Peak fractions were pooled and applied to a Superdex 200 XK 26/60 column (GE Biosciences) equilibrated with; 20 mM Tris (pH 7.8), 0.15M NaCl, 10%

glycerol and 0.1% CHAPS. Protein identity was confirmed by Edman sequencing and  $\alpha 2\beta 2$  heterodimer formation was detected by light scattering. Protein concentration was determined according to the calculated molar extinction coefficient at 280 nm, and enzyme was typically snap frozen in liquid nitrogen and stored at  $-80^{\circ}\text{C}$ .

[0270] The following table includes PHD2, CPH1, and CPH2  $\text{IC}_{50}$  values obtained using the procedures set forth herein for Comparative and Example compounds described herein. As shown in the following table, replacement of the N atom with a C atom in the side chain results in a significant and surprising increase in selectivity of a compound for PHD2 with respect to both CPH1 and CPH2 in the compounds of the invention. Therefore, in some embodiments, the invention provides a compound of any of the embodiments in which the selectivity of the compound for PHD2 with respect to CPH1 is greater than 5, greater than 8, greater than 10, greater than 15, greater than 20, or is even higher. The selectivity for these purposes, can be determined by dividing the CPH1  $\text{IC}_{50}$  value of the compound by the PHD2  $\text{IC}_{50}$  value of the compound where the  $\text{IC}_{50}$  values are determined using the methods presented herein.

Stimulation of Erythropoietin by Compounds of the Invention

[0271] Female Sprague-Dawley rats (Charles River Laboratories, Wilmington, MA) weighing approximately 220-240 grams, were given a single *per os* administration of the test compound(s) or vehicle (2% hydroxypropylmethylcellulose, 1% Tween 80, 0.075N NaOH, pH 9 with HCl) via oral gavage with an 18 gauge 2" disposable feeding needle (Popper and Sons, New Hyde Park, NY). Approximately 150 $\mu$ L of blood was collected from the tail vein using a 23 gauge 3/4" butterfly needle at various time points between 0.5 and 48 hours post-administration. Blood was transferred into collection tubes containing EDTA (Greiner Bio-One, Kremsmunster, Austria), and centrifuged at 10,000 rpm at 4 degrees centigrade for 8 minutes for plasma collection. At 48 hours post-administration, animals were sacrificed via CO<sub>2</sub> inhalation and 3-4 mL of blood was collected via cardiac puncture with a 20 gauge 1" needle, and aliquoted into collection tubes containing EDTA and into serum separator tubes (Greiner Bio-One, Kremsmunster, Austria). Blood was centrifuged as described above for plasma and serum collection. The resulting plasma from each time point was analyzed for erythropoietin using a MSD rat EPO assay (Meso Scale Discovery, Gaithersburg, MD) and the results are shown in Figure 4. Each of Example compounds 4, 7, and 8 produced a dramatic increase in erythropoietin following administration as is clear when compared with the data corresponding to administration of vehicle.
