(57) **Abrégé/Abstract:**

A cathode material for a lithium-ion secondary battery of the present invention is active material particles including central particles represented by General Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ ($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y) and a carbonaceous film that coats surfaces of the central particles, in which a coarse particle ratio in a particle size distribution is 35% or more and 65% or less.

ABSTRACT OF THE DISCLOSURE

A cathode material for a lithium-ion secondary battery of the present invention is active material particles including
5 central particles represented by General Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$
($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here, A represents
at least one element selected from the group consisting of Co,
Mn, Ni, Fe, Cu, and Cr, and D represents at least one element
selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn,
10 B, Al, Ga, In, Si, Ge, Sc, and Y) and a carbonaceous film that
coats surfaces of the central particles, in which a coarse particle
ratio in a particle size distribution is 35% or more and 65%
or less.

ACTIVE LITHIUM-ION CATHODE MATERIAL WITH IMPROVED PARTICLE SIZE
DISTRIBUTION, CATHODE USING THIS MATERIAL, AND BATTERY USING
THIS CATHODE

5 CROSS-REFERENCE TO RELATED APPLICATIONS

[0001]

This application claims the benefit of Japanese Patent
Application No. 2017-059179 filed March 24, 2017.

10 BACKGROUND OF THE INVENTION

Field of the Invention

[0002]

The present invention relates to a cathode material for
a lithium-ion secondary battery, a cathode for a lithium-ion
15 secondary battery, and a lithium-ion secondary battery.

Description of Related Art

[0003]

In recent years, as batteries anticipated to have a small
20 size and a high capacity and weigh less, non-aqueous electrolytic
solution-based secondary batteries such as lithium-ion secondary
batteries have been proposed and put into practical use.
Lithium-ion secondary batteries are constituted of a cathode
and an anode which have properties capable of reversibly
25 intercalating and deintercalating lithium ions, and a non-aqueous

electrolyte.

[0004]

As anode active materials for anode materials of lithium-ion secondary batteries, generally, carbon-based materials or
5 Li-containing metal oxides having properties capable of reversibly intercalating and deintercalating lithium ions are used. Examples of the Li-containing metal oxides include lithium titanate ($\text{Li}_4\text{Ti}_5\text{O}_{12}$).

[0005]

10 Meanwhile, as cathodes of lithium-ion secondary batteries, cathode material mixtures including a cathode material, a binder, and the like are used. As the cathode active material, for example, Li-containing metal oxides having properties capable of reversibly intercalating and deintercalating lithium ions such
15 as lithium iron phosphate (LiFePO_4) are used. In addition, cathodes of lithium-ion secondary batteries are formed by applying the cathode material mixture onto the surface of a metal foil that is called an electrode current collector.

[0006]

20 As electrolytic solutions for lithium-ion secondary batteries, non-aqueous solvents are used. Non-aqueous solvents enable the application of cathode active materials that are oxidized and reduced at a high potential or anode active materials that are oxidized and reduced at a low potential. Therefore,
25 lithium-ion secondary batteries having a higher voltage can be

realized.

[0007]

These lithium-ion secondary batteries have a small size and a higher energy and weigh less than secondary batteries in the related art such as lead batteries, nickel cadmium batteries, and nickel metal hydride batteries. Therefore, lithium-ion secondary batteries are used not only as small-size power supplies used in portable electronic devices such as mobile phones and notebook personal computers but also as large-size stationary emergency power supplies.

[0008]

In recent years, there has been a demand for the performance improvement of lithium-ion secondary batteries, and a variety of studies have been carried out. For example, in a case in which a lithium-ion secondary battery is used in a high-current density region, there is a demand for additional improvement in electron conductivity in order to improve the performance. Regarding the above-described property demands, techniques for coating the surfaces of cathode active materials with a carbonaceous material (hereinafter, in some cases, referred to as "carbonaceous film") are known (for example, refer to Japanese Laid-open Patent Publication No. 2009-004371, Japanese Laid-open Patent Publication No. 2011-049161, and Japanese Laid-open Patent Publication No. 2012-104290). As a method for coating the surface of a cathode active material with a carbonaceous film, methods

in which a cathode active material and a carbon source are mixed together and this mixture is calcinated in an inert atmosphere or a reducing atmosphere are known.

5

SUMMARY OF THE INVENTION

[0009]

When the cathode density is improved by filling the carbonaceous film that coats the surface of the cathode active material with a larger amount of a cathode active material, the energy density per unit volume improves. However, in a case in which the cathode active material agglomerates and thus forms agglomerates, voids are generated among the cathode active material particles in the carbonaceous film, and thus there is a problem in that the cathode density decreases. Therefore, techniques in which the agglomerates made of the cathode active material are cracked in a gas phase or the like so as to decrease the agglomerate diameter, and voids among the cathode active material particles are efficiently filled with the cathode active material, thereby improving the energy density per unit volume is known.

20

[0010]

However, in a case in which a cathode material including the primary particles of a cathode active material such as lithium iron phosphate and a carbonaceous film that coats the surfaces of the primary particles is cracked, when the cracking intensity

25

is too high, the carbonaceous film is peeled off from the surfaces of the primary particles, and thus the electron conductivity decreases. A decrease in the electron conductivity causes the deterioration of input and output characteristics or a decrease in the capacity after charge and discharge cycles, which is not preferable. In addition, when the cracking intensity is too low, the cathode density decrease, which is not preferable.

[0011]

For the above-described reasons, it is most preferable to crack the cathode material to necessary agglomerate particle sizes while guaranteeing the electron conductivity by suppressing the peeling of the carbonaceous film. However, the cracking intensity at which the carbonaceous film begins to peel off varies depending on the primary particle diameter of the cathode active material, the amount of carbon included in the cathode material, or the like, and thus it is difficult to optimally control the cracking intensity.

[0012]

The present invention has been made in consideration of the above-described circumstances, and an object of the present invention is to provide a cathode material for a lithium-ion secondary battery which suppresses the peeling of a carbonaceous film that coats the surfaces of primary particles of a cathode active material and is capable of improving the cathode density while guaranteeing the electron conductivity, a cathode for a

lithium-ion secondary battery including the cathode material for a lithium-ion secondary battery, and a lithium-ion secondary battery including the cathode for a lithium-ion secondary battery.

5 [0013]

The present inventors and the like carried out intensive studies in order to achieve the above-described object, consequently found that, in active material particles including central particles represented by General Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ (0.9 < x < 1.1, 0 < y ≤ 1, 0 ≤ z < 1, and 0.9 < y + z < 1.1; here, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y) and a carbonaceous film that coats surfaces of the central particles, when, in a particle size distribution, a ratio (hereinafter, also referred to as "coarse particle ratio") of an area surrounded by a curve indicating a peak (maximum) shape of coarse particles (hereinafter, in some cases, also referred to as "coarse particle-side peak area") to a sum of the area surrounded by the curve indicating the peak (maximum) shape of the coarse particles and an area surrounded by a curve indicating a peak (maximum) shape of fine particles (hereinafter, in some cases, also referred to as "fine particle-side peak area") is set to 35% or more and 65% or less, it is possible to suppress the peeling

of the carbonaceous film that coats the surfaces of primary particles of the central particles and provide a cathode material for a lithium-ion secondary battery capable of improving the cathode density while guaranteeing the electron conductivity, and completed the present invention.

[0014]

A cathode material for a lithium-ion secondary battery of the present invention is active material particles including central particles represented by General Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ ($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y) and a carbonaceous film that coats surfaces of the central particles, in which a coarse particle ratio in a particle size distribution is 35% or more and 65% or less.

[0015]

A cathode for a lithium-ion secondary battery of the present invention is a cathode for a lithium-ion secondary battery including an electrode current collector and a cathode mixture layer formed on the electrode current collector, in which the cathode mixture layer includes the cathode material for the lithium-ion secondary battery of the present invention.

[0016]

A lithium-ion secondary battery of the present invention includes the cathode for the lithium-ion secondary battery of the present invention.

[0017]

5 According to the cathode material for the lithium-ion secondary battery of the present invention, since the coarse particle ratio in the particle size distribution is 35% or more and 65% or less, it is possible to suppress the peeling of the carbonaceous film that coats the surfaces of the central particles
10 and provide a cathode material for a lithium-ion secondary battery capable of improving the cathode density while guaranteeing the electron conductivity.

[0018]

 According to the cathode for the lithium-ion secondary
15 battery of the present invention, since the cathode material for the lithium-ion secondary battery of the present invention is included, a lithium-ion secondary battery having a high energy density and excellent input and output characteristics can be obtained.

20 [0019]

 According to the lithium-ion secondary battery of the present invention, since the cathode for the lithium-ion secondary battery of the present invention is included, a lithium-ion secondary battery having a high energy density and
25 excellent input and output characteristics can be obtained.

BRIEF DESCRIPTION OF THE DRAWINGS

[0020]

FIG. 1 is a scanning electron microscopic image illustrating
5 agglomerates.

FIG. 2 is a scanning electron microscopic image illustrating
cracked particles.

FIG. 3 is a graph illustrating a particle size distribution
of a cathode material in Example 1.

10 FIG. 4 is a graph illustrating a particle size distribution
of a cathode material in Comparative Example 3.

DETAILED DESCRIPTION OF THE INVENTION

[0021]

15 Embodiments of a cathode material for a lithium-ion
secondary battery, a cathode for a lithium-ion secondary battery,
and a lithium-ion secondary battery of the present invention
will be described.

[0022]

20 Meanwhile, the present embodiment is specific description
for better understanding of the gist of the invention and does
not limit the present invention unless particularly otherwise
described.

[0023]

25 Cathode material for lithium-ion secondary battery

A cathode material for a lithium-ion secondary battery of the present embodiment (hereinafter, in some cases, simply referred to as "cathode material") is active material particles including central particles represented by General Formula

5 $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ ($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y) and a carbonaceous

10 film that coats surfaces of the central particles, in which a coarse particle ratio in a particle size distribution is 35% or more and 65% or less.

[0024]

In addition, the cathode material for a lithium-ion

15 secondary battery of the present embodiment is cracked particles which are produced using a method for manufacturing a cathode material for a lithium-ion secondary battery described below and are formed by cracking active material particles made of agglomerates of primary particles. In the cathode material for

20 a lithium-ion secondary battery of the present embodiment, the agglomerate refers to a substance allowing the differentiation of individual secondary particles in particle shapes observed using a scanning electron microscope (SEM) at a magnification of 1,000 times as illustrated in FIG. 1. Meanwhile, the cracked

25 particles refer to a substance in a state in which the

differentiation of individual particles is not allowed in particle shapes observed using a scanning electron microscope (SEM) at a magnification of 1,000 times as illustrated in FIG. 2.

5 [0025]

The average primary particle diameter of the cathode material for a lithium-ion secondary battery (active material particles) of the present embodiment is preferably 10 nm or more and 700 nm or less and more preferably 20 nm or more and 500
10 nm or less.

[0026]

When the average primary particle diameter of the cathode material is 10 nm or more, the specific surface area of the cathode material increases, and thus an increase in the mass of necessary
15 carbon is suppressed, and it is possible to suppress a decrease in the charge and discharge capacity of lithium-ion secondary batteries. On the other hand, when the average primary particle diameter of the cathode material is 700 nm or less, it is possible to suppress the extension of the time taken for lithium ions
20 or electrons to migrate in the cathode material. Therefore, it is possible to suppress the deterioration of the output characteristics attributed to an increase in the internal resistance of lithium-ion secondary batteries.

[0027]

25 Here, the average particle diameter refers to the

volume-average particle diameter. The average primary particle diameter of the primary particles of the cathode material can be measured using a laser diffraction and scattering particle size distribution measurement instrument or the like. In
5 addition, the average particle diameter of a plurality of primary particles that are arbitrarily selected and observed using a scanning electron microscope (SEM) may also be computed.

[0028]

The cathode material for a lithium-ion secondary battery
10 of the present embodiment has a peak (maximum) of coarse particles and a peak (maximum) of fine particles in the particle size distribution (refer to FIG. 3).

[0029]

In the cathode material for a lithium-ion secondary battery
15 of the present embodiment, the ratio (coarse particle ratio) of an area surrounded by a curve indicating the peak (maximum) shape of coarse particles (coarse particle-side peak area) to the sum of the area surrounded by the curve indicating the peak (maximum) shape of the coarse particles and an area surrounded
20 by a curve indicating the peak (maximum) shape of fine particles (fine particle-side peak area) is 35% or more and 65% or less and preferably 40% or more and 60% or less.

[0030]

When the coarse particle ratio is 35% or more, the peeling
25 of the carbonaceous film is suppressed, and thus the electron

conductivity of the cathode material improves, and it is possible to realize sufficient charge and discharge rate performance. When the coarse particle ratio is 65% or less, it becomes possible to densely fill cathodes with the cathode active material (central particles) during the production of the cathodes including the cathode material for a lithium-ion secondary battery, and the energy density per unit volume of the cathodes improves.

[0031]

The coarse particle ratio in the particle size distribution can be measured using a laser diffraction and scattering particle size distribution measurement instrument or the like and can be computed from the coarse particle-side peak area and the fine particle-side peak area in particle size distributions exhibiting bimodality.

[0032]

The cathode material for a lithium-ion secondary battery of the present embodiment is a cathode material which is produced using a method for manufacturing a cathode material for a lithium-ion secondary battery described below and is formed by cracking active material particles made of the agglomerates of primary particles, and the maximum value of fine particles in the particle size distribution is preferably 0.15 μm or more and 0.35 μm or less and more preferably 0.18 μm or more and 0.32 μm or less.

[0033]

When the maximum value of fine particles in the particle size distribution is 0.15 μm or more and 0.35 μm or less, the electron conductivity of the cathode material in which the peeling of the carbonaceous film that coats the surfaces of the primary
5 particles of the central particles is suppressed improves.

[0034]

The maximum value of coarse particles in the particle size distribution of the cathode material for a lithium-ion secondary battery is preferably 0.80 μm or more and 1.20 μm or less and
10 more preferably 0.85 μm or more and 1.15 μm or less.

[0035]

When the maximum value of coarse particles in the particle size distribution is 0.80 μm or more and 1.20 μm or less, it becomes possible to densely fill cathodes with the cathode
15 material during the production of the cathodes including the cathode material for a lithium-ion secondary battery, and the energy density per unit volume of the cathodes improves.

[0036]

The amount of carbon included in the cathode material for
20 a lithium-ion secondary battery, that is, the amount of carbon that forms the carbonaceous film is preferably 0.1 parts by mass or more and 10 parts by mass or less and more preferably 0.6 parts by mass or more and 3 parts by mass or less with respect to 100 parts by mass of the central particles.

25 [0037]

When the amount of carbon is 0.1 parts by mass or more, the discharge capacity of lithium-ion secondary batteries at a high charge-discharge rate increases, and it is possible to realize sufficient charge and discharge rate performance. On the other hand, when the amount of carbon is 10 parts by mass or less, it is possible to suppress the battery capacity of lithium-ion secondary batteries per unit mass of the cathode material being decreased more than necessary.

[0038]

The powder resistance value of the cathode material for a lithium-ion secondary battery is preferably 100 $\Omega\cdot\text{cm}$ or less and more preferably 80 $\Omega\cdot\text{cm}$ or less.

[0039]

When the powder resistance value is 100 $\Omega\cdot\text{cm}$ or less, it is possible to improve the electron conductivity of the cathode material and a cathode mixture layer formed on an electrode current collector.

[0040]

The powder resistance value can be measured from a specimen obtained by shaping the cathode material at a pressure of 50 MPa and, specifically, can be measured using a method described in examples.

[0041]

The carbon supporting amount with respect to the specific surface area of the primary particles of the central particles

constituting the cathode material for a lithium-ion secondary battery ("[the carbon supporting amount]/[the specific surface area of the primary particles of the central particles]"; hereinafter, referred to as "the carbon supporting amount ratio") is preferably 0.01 g/m² or more and 0.5 g/m² or less and more preferably 0.03 g/m² or more and 0.3 g/m² or less.

[0042]

When the carbon supporting amount ratio is 0.01 g/m² or more, the discharge capacity of lithium-ion secondary batteries at a high charge-discharge rate increases, and it is possible to realize sufficient charge and discharge rate performance. On the other hand, when the carbon supporting amount ratio is 0.5 g/m² or less, it is possible to suppress the battery capacity of lithium-ion secondary batteries per unit mass of the cathode material being decreased more than necessary.

[0043]

The BET specific surface area of the cathode material for a lithium-ion secondary battery is preferably 5 m²/g or more and 25 m²/g or less.

[0044]

When the BET specific surface area is 5 m²/g or more, the coarsening of the cathode material is suppressed, and thus it is possible to increase the diffusion rate of lithium ions among the particles. Therefore, it is possible to improve the battery characteristics of lithium-ion secondary batteries. On the

other hand, when the BET specific surface area is $25 \text{ m}^2/\text{g}$ or less, it is possible to increase the cathode density in cathodes including the cathode material for a lithium-ion secondary battery of the present embodiment. Therefore, it is possible to provide lithium-ion secondary batteries having a high energy density.

[0045]]

The median diameter of the cathode material for a lithium-ion secondary battery is preferably $0.50 \text{ }\mu\text{m}$ or more and $0.80 \text{ }\mu\text{m}$ or less and more preferably $0.55 \text{ }\mu\text{m}$ or more and $0.75 \text{ }\mu\text{m}$ or less.

[0046]

When the median diameter is $0.50 \text{ }\mu\text{m}$ or more, it is possible to prevent electron conductivity from being decreased due to excessive cracking. On the other hand, when the median diameter is $0.80 \text{ }\mu\text{m}$ or less, it becomes possible to densely fill cathodes with the cathode active material (central particles) during the production of the cathodes including the cathode material for a lithium-ion secondary battery, and the energy density per unit volume improves.

[0047]

The median diameter refers to the particle diameter of a void for which the distribution curve of the integral percentage in the particle size distribution intersects the horizontal axis at 50%.

[0048]

The chromaticity b^* in the $L^*a^*b^*$ color space of the cathode material for a lithium-ion secondary battery is preferably 1.9 or more and 2.3 or less and more preferably 1.95 or more and
5 2.3 or less.

[0049]

The chromaticity b^* of the cathode material for a lithium-ion secondary battery is an index indicating the degree of coating of the central particles with the carbonaceous film.

10 [0050]

When the chromaticity b^* is 1.9 or more, it becomes possible to densely fill cathodes with the cathode active material (central particles) during the production of the cathodes including the cathode material for a lithium-ion secondary battery, and the
15 energy density per unit volume improves. On the other hand, when the chromaticity b^* is 2.3 or less, in the cathode material for a lithium-ion secondary battery, it is possible to set the degree of exposure of central particles that are not coated with the carbonaceous film in a range enough to increase the energy density
20 per unit volume, and it is possible to prevent electron conductivity from being decreased due to excessive cracking.

[0051]

Central particles

The central particles constituting the cathode material
25 for a lithium-ion secondary battery of the present embodiment

are made of a cathode active material represented by General
Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ ($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here,
A represents at least one element selected from the group
consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at
5 least one element selected from the group consisting of Mg, Ca,
Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y).

[0052]

Examples of compounds represented by General Formula
 $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ include LiFePO_4 , LiMnPO_4 , LiCoPO_4 , LiFeMnPO_4 , LiMnZnPO_4 ,
10 and the like.

[0053]

The average primary particle diameter of the primary
particles of the central particles constituting the cathode
material particles for a lithium-ion secondary battery of the
15 present embodiment is preferably 5 nm or more and 800 nm or less
and more preferably 20 nm or more and 500 nm or less.

[0054]

When the average primary particle diameter of the primary
particles of the central particles is 5 nm or more, it is possible
20 to sufficiently coat the surfaces of the primary particles of
the central particles with the carbonaceous film. In addition,
it is possible to increase the discharge capacity of lithium-ion
secondary batteries during high-speed charge and discharge and
realize sufficient charge and discharge performance. On the
25 other hand, when the average primary particle diameter of the

primary particles of the central particles is 800 nm or less,
it is possible to decrease the internal resistance of the primary
particles of the central particles. In addition, it is possible
to increase the discharge capacity of lithium-ion secondary
5 batteries during high-speed charge and discharge.

[0055]

Carbonaceous film

The carbonaceous film coats the surfaces of the central
particles.

10 [0056]

When the surfaces of the central particles are coated with
the carbonaceous film, it is possible to improve the electron
conductivity of the cathode material for a lithium-ion secondary
battery.

15 [0057]

The thickness of the carbonaceous film is preferably 0.2
nm or more and 10 nm or less and more preferably 0.5 nm or more
and 4 nm or less.

[0058]

20 When the thickness of the carbonaceous film is 0.2 nm or
more, it is possible to prevent the excessively thin thickness
of the carbonaceous film from disabling the formation of films
having a desired resistance value. In addition, it is possible
to ensure conductive properties suitable for the cathode material
25 for a lithium-ion secondary battery. On the other hand, when

the thickness of the carbonaceous film is 10 nm or less, it is possible to suppress a decrease in the battery capacity per unit mass of the cathode material for a lithium-ion secondary battery.

[0059]

5 In addition, when the thickness of the carbonaceous film is 0.2 nm or more and 10 nm or less, it becomes easy to closely pack the cathode material for a lithium-ion secondary battery, and thus the amount of the cathode material for a lithium-ion secondary battery packed per unit volume of the cathode increases.
10 As a result, it is possible to increase the cathode density, and high-capacity lithium-ion secondary batteries can be obtained.

[0060]

 The coating ratio of the carbonaceous film with respect
15 to the central particles is preferably 60% or more and 95% or less and more preferably 80% or more and 95% or less. When the coating ratio of the carbonaceous film is 60% or more, the coating effect of the carbonaceous film can be sufficiently obtained.

[0061]

20 The density of the carbonaceous film, which is calculated using the carbon amount of the carbonaceous film, is preferably 0.3 g/cm^3 or more and 1.5 g/cm^3 or less and more preferably 0.4 g/cm^3 or more and 1.0 g/cm^3 or less.

[0062]

25 Here, the reasons for limiting the density of the

carbonaceous film, which is calculated using the carbon amount of the carbonaceous film, to the above-described range are as described below. When the density of the carbonaceous film, which is calculated using the carbon amount of the carbonaceous film, is 0.3 g/cm³ or more, the carbonaceous film exhibits sufficient electron conductivity. Meanwhile, when the density of the carbonaceous film is 1.5 g/cm³ or less, the amount of the fine crystals of graphite made of a lamellar structure in the carbonaceous film is small, and thus no steric hindrance is generated by the fine crystals of the graphite during the diffusion of lithium ions in the carbonaceous film. Therefore, there is no case in which the lithium ion migration resistance increases. As a result, there is no case in which the internal resistance of lithium-ion secondary batteries increases, and voltage drop does not occur at a high charge-discharge rate of lithium-ion secondary batteries.

[0063]

According to the cathode material for a lithium-ion secondary battery of the present embodiment, in the active material particles including the central particles represented by General Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ ($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge,

Sc, and Y) and the carbonaceous film that coats the surfaces of the central particles, the coarse particle ratio in the particle size distribution is set to 35% or more and 65% or less, and thus it is possible to suppress the peeling of the carbonaceous film that coats the surfaces of the primary particles of the cathode active material (central particles) and provide a cathode material for a lithium-ion secondary battery capable of improving the cathode density while guaranteeing the electron conductivity.

[0064]

10 Method for manufacturing cathode material for lithium-ion secondary battery

The cathode material for a lithium-ion secondary battery of the present embodiment can be manufactured by cracking active material particles made of agglomerates.

15 [0065]

Method for manufacturing active material particles

A method for manufacturing active material particles in the present embodiment includes, for example, a manufacturing step of the central particles and a precursor of the central particles, a slurry preparation step of preparing a slurry by mixing at least one central particle raw material selected from the group consisting of the central particles and the precursor of the central particles, an organic compound which is a carbonaceous film precursor, and water, and a calcination step of drying the slurry and calcinating the obtained dried substance

in a non-oxidative atmosphere.

[0066]

Step of manufacturing central particles and precursor of central particles

5 As a method for manufacturing the compound (the central particles) represented by $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ ($0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$; here, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group
10 consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y), a method of the related art such as a solid phase method, a liquid phase method, and a gas phase method is used. Examples of $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ obtained using the above-described method include particulate substances (hereinafter, in some cases,
15 referred to as " $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ particles").

[0067]

The $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ particles is obtained by, for example, hydrothermally synthesizing a slurry-form mixture obtained by mixing a Li source, an A source, a P source, water, and, if necessary,
20 a D source. By means of hydrothermal synthesis, $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ is generated as a precipitate in water. The obtained precipitate may be a precursor of $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$. In this case, target $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ particles are obtained by calcinating the precursor of $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$.

[0068]

25 In this hydrothermal synthesis, a pressure-resistant

airtight container is preferably used.

[0069]

Here, examples of the Li source include lithium salts such as lithium acetate (LiCH_3COO) and lithium chloride (LiCl), lithium hydroxide (LiOH), and the like. Among these, as the Li source, at least one selected from the group consisting of lithium acetate, lithium chloride, and lithium hydroxide is preferably used.

[0070]

Examples of the A source include chlorides, carboxylates, sulfates, and the like which include at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr. For example, in a case in which A in $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ is Fe, examples of the Fe source include divalent iron salts such as iron (II) chloride (FeCl_2), iron (II) acetate ($\text{Fe}(\text{CH}_3\text{COO})_2$), and iron (II) sulfate (FeSO_4). Among these, as the Fe source, at least one selected from the group consisting of iron (II) chloride, iron (II) acetate, and iron (II) sulfate is preferably used.

[0071]

Examples of the D source include chlorides, carboxylates, sulfates, and the like which include at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y.

[0072]

Examples of the P source include phosphoric acid compounds such as phosphoric acid (H_3PO_4), ammonium dihydrogen phosphate

($\text{NH}_4\text{H}_2\text{PO}_4$), diammonium hydrogen phosphate ($(\text{NH}_4)_2\text{HPO}_4$), and the like. Among these, as the P source, at least one selected from the group consisting of phosphonic acid, ammonium dihydrogen phosphate, and diammonium hydrogen phosphate is preferably used.

5 [0073]

Slurry preparation step

By means of the slurry preparation step, the organic compound which is the precursor of the carbonaceous film is interposed among the central particles, and the organic compound
10 and the central particles are uniformly mixed together, and thus the surfaces of the central particles can be uniformly coated with the organic compound.

[0074]

Furthermore, by means of the calcination step, the organic
15 compound that coats the surfaces of the central particles are carbonized, thereby obtaining active material particles (cathode material) including the central particles that are uniformly coated with the carbonaceous film.

[0075]

20 The organic compound that is used in the method for manufacturing active material particles in the present embodiment is not particularly limited as long as the compound is capable of forming the carbonaceous film on the surfaces of the central particles. Examples of the above-described organic compound
25 include divalent alcohols such as polyvinyl alcohol (PVA),

polyvinyl pyrrolidone, cellulose, starch, gelatin,
carboxymethyl cellulose, methyl cellulose, hydroxymethyl
cellulose, hydroxyethyl cellulose, polyacrylic acid,
polystyrene sulfonate, polyacrylamide, polyvinyl acetate,
5 glucose, fructose, galactose, mannose, maltose, sucrose, lactose,
glycogen, pectin, alginic acid, glucomannan, chitin, hyaluronic
acid, chondroitin, agarose, polyethers, and ethylene glycol,
trivalent alcohols such as glycerin, and the like.

[0076]

10 In the slurry preparation step, the central particle raw
material and the organic compound are dissolved or dispersed
in water, thereby preparing a homogeneous slurry.

[0077]

In the dissolution or dispersion of these raw materials
15 in water, it is also possible to add a dispersant thereto.

[0078]

A method for dissolving or dispersing the central particle
raw material and the organic compound in water is not particularly
limited as long as the central particle raw material is dispersed
20 in water and the organic compound is dissolved or dispersed in
water. The above-described method is preferably a method in which
a medium stirring-type dispersion device that stirs medium
particles at a high rate such as a planetary ball mill, an
oscillation ball mill, a bead mill, a paint shaker, or an attritor
25 is used.

[0079]

When the central particle raw material and the organic compound are dissolved or dispersed in water, it is preferable to disperse the central particle raw material in water in a primary particle form, then, add the organic compound to water, and stir the organic compound so as to be dissolved or dispersed. In such a case, the surfaces of the primary particles of the central particle raw material are easily coated with the organic compound. Therefore, the organic compound is uniformly dispersed on the surfaces of the primary particles of the central particle raw material, and consequently, the surfaces of the primary particles of the central particles are coated with the carbonaceous film derived from the organic compound.

[0080]

15 Calcination step

Next, the slurry prepared in the slurry preparation step is sprayed and dried in a high-temperature atmosphere, for example, in the atmosphere of 70°C or higher and 250°C or lower.

[0081]

20 Next, the obtained dried substance is calcinated in a non-oxidative atmosphere at a temperature of preferably 500°C or higher and 1,000°C or lower and more preferably 600°C or higher and 1,000°C or lower for 0.1 hours or longer and 40 hours or shorter.

[0082]

25 The non-oxidative atmosphere is preferably an atmosphere

filled with an inert gas such as nitrogen (N_2), argon (Ar), or the like. In a case in which it is necessary to further suppress the oxidation of the dried substance, a reducing atmosphere including approximately several percentages by volume of a reducing gas such as hydrogen (H_2) is preferred. In addition, for the purpose of removing organic components evaporated in the non-oxidative atmosphere during the calcination, a susceptible or burnable gas such as oxygen (O_2) may be introduced into the non-oxidative atmosphere.

10 [0083]

Here, when the calcination temperature is set to 500°C or higher, it is easy for the organic compound in the dried substance to be sufficiently decomposed and reacted, and the organic compound is easily and sufficiently carbonized. As a result, it is easy to prevent the generation of a high-resistance decomposed substance of the organic compound in the obtained agglomerates. Meanwhile, when the calcination temperature is set to $1,000^\circ\text{C}$ or lower, lithium (Li) in the central particle raw material is not easily evaporated, and the particle growth of the central particles to a size that is equal to or larger than the target size is suppressed. As a result, in a case in which lithium-ion secondary batteries including a cathode including the cathode material of the present embodiment are produced, it is possible to prevent the discharge capacity at a high charge-discharge rate from decreasing, and it is possible

15
20
25

to realize lithium-ion secondary batteries having sufficient charge and discharge rate performance.

[0084]

By means of the above-described steps, active material
5 particles made of agglomerates in which the surfaces of the primary particles of the central particles are coated with carbon (the carbonaceous film) generated by the thermal decomposition of the organic compound in the dried substance are obtained.

[0085]

10 Cracking step of active material particles

Next, at least some of the active material particles made of the agglomerates are cracked. Here, in order to "crack at least some of the active material particles made of the agglomerates", at least some of the agglomerates need to be cracked,
15 and not all of the agglomerates need to be cracked.

[0086]

A device that is used for the cracking of the agglomerates needs to be capable of cracking not all of the agglomerates but some of the agglomerates, and, for example, an air flow-type
20 fine crusher such as a dry-type ball mill, a wet-type ball mill, a mixer, or a jet mill, an ultrasonic crusher, or the like is used.

[0087]

In the present embodiment, a jet mill is preferably used
25 for the cracking since the damage of the active material particles

(the central particles and the primary particles) is suppressed.

[0088]

In addition, the supply rate of the agglomerates into the jet mill is preferably set to 50 g/hour to 1,500 g/hour, and the air pressure is preferably set to 0.3 MPa to 0.7 MPa. The cracking intensity can be freely adjusted by varying the supply rate of the agglomerates being injected into the jet mill. In addition, the coarse particle ratio in the particle size distribution of the cathode material for a lithium-ion secondary battery can be adjusted by adjusting the cracking intensity. Here, in a case in which the cracking intensity is strong, the coarse particle ratio becomes a small value, and the degree of exposure of central particles that are not coated with the carbonaceous film increases in the cathode material for a lithium-ion secondary battery. Meanwhile, the cracking intensity refers to the supply rate (g/hour) of the agglomerates when the above-described air pressure is fixed in the case of using, for example, a jet mill, and the cracking intensity becomes stronger as the supply rate decreases and becomes weaker as the supply rate increases.

[0089]

Cathode for lithium-ion secondary battery

A cathode for a lithium-ion secondary battery of the present embodiment (hereinafter, in some cases, referred to as "cathode") includes the cathode material for a lithium-ion secondary battery

of the present embodiment. In more detail, the cathode of the present embodiment includes an electrode current collector made of a metal foil and a cathode mixture layer formed on the electrode current collector, and the cathode mixture layer includes the cathode material for a lithium-ion secondary battery of the present embodiment. That is, the cathode of the present embodiment is obtained by forming a cathode mixture layer on one main surface of the electrode current collector using the cathode material for a lithium-ion secondary battery of the present embodiment.

[0090]

Since the cathode for a lithium-ion secondary battery of the present embodiment includes the cathode material for a lithium-ion secondary battery of the present embodiment, lithium-ion secondary batteries for which the cathode for a lithium-ion secondary battery of the present embodiment is used have a high energy density and have excellent input and output characteristics.

[0091]

Method for manufacturing cathode for lithium-ion secondary battery

The method for manufacturing the cathode for a lithium-ion secondary battery of the present embodiment is not particularly limited as long as the cathode mixture layer can be formed on one main surface of the electrode current collector using the

cathode material for a lithium-ion secondary battery of the present embodiment. Examples of the method for manufacturing the cathode of the present embodiment include the following method.

5 [0092]

First, the cathode material for a lithium-ion secondary battery of the present embodiment, a binding agent made of a binder resin, and a solvent are mixed together, thereby preparing cathode material paste. At this time, to the cathode material
10 paste in the present embodiment, a conductive auxiliary agent such as carbon black may be added if necessary.

[0093]

Binding agent

As the binding agent, that is, the binder resin, for example,
15 a polytetrafluoroethylene (PTFE) resin, a polyvinylidene fluoride (PVdF) resin, fluorine rubber, or the like is preferably used.

[0094]

The blending amount of the binding agent used to prepare
20 the cathode material paste is not particularly limited and is, for example, preferably 1 part by mass or more and 30 parts by mass or less and more preferably 3 parts by mass or more and 20 parts by mass or less with respect to 100 parts by mass of the cathode material for a lithium-ion secondary battery.

25 [0095]

When the blending amount of the binding agent is 1 part by mass or more, it is possible to sufficiently improve the binding property between the cathode mixture layer and the electrode current collector. Therefore, it is possible to prevent the cathode mixture layer from being cracked or dropped during the formation of the cathode mixture layer by means of rolling or the like. In addition, it is possible to prevent the cathode mixture layer from being peeled off from the electrode current collector in processes of charging and discharging lithium-ion secondary batteries and prevent the battery capacity or the charge-discharge rate from being decreased. On the other hand, when the blending amount of the binding agent is 30 parts by mass or less, it is possible to prevent the internal resistance of the cathode material for a lithium-ion secondary battery from being decreased and prevent the battery capacity at a high charge-discharge rate from being decreased.

[0096]

Conductive auxiliary agent

The conductive auxiliary agent is not particularly limited, and, for example, at least one element selected from the group consisting of particulate carbon such as acetylene black (AB), KETJEN BLACK, and furnace black and fibrous carbon such as vapor-grown carbon fiber (VGCF) and carbon nanotube is used.

[0097]

Solvent

The solvent that is used in the cathode material paste including the cathode material for a lithium-ion secondary battery of the present embodiment is appropriately selected depending on the properties of the binding agent. When the
5 solvent is appropriately selected, it is possible to facilitate the cathode material paste to be applied to substances to be coated such as the electrode current collector.

[0098]

Examples of the solvent include water, alcohols such as
10 methanol, ethanol, 1-propanol, 2-propanol (isopropyl alcohol: IPA), butanol, pentanol, hexanol, octanol, and diacetone alcohol, esters such as ethyl acetate, butyl acetate, ethyl lactate, propylene glycol monomethyl ether acetate, propylene glycol monoethyl ether acetate, and γ -butyrolactone, ethers such as
15 diethyl ether, ethylene glycol monomethyl ether (methyl cellosolve), ethylene glycol monoethyl ether (ethyl cellosolve), ethylene glycol monobutyl ether (butyl cellosolve), diethylene glycol monomethyl ether, and diethylene glycol monoethyl ether, ketones such as acetone, methyl ethyl ketone (MEK), methyl
20 isobutyl ketone (MIBK), acetylacetone, and cyclohexanone, amides such as dimethyl formamide, N,N-dimethylacetoacetamide, and N-methyl-2-pyrrolidone (NMP), glycols such as ethylene glycol, diethylene glycol, and propylene glycol, and the like. These solvents may be used singly, or a mixture of two or more solvents
25 may be used.

[0099]

The content rate of the solvent in the cathode material paste is preferably 50% by mass or more and 70% by mass or less and more preferably 55% by mass or more and 65% by mass or less
5 in a case in which the total mass of the cathode material for a lithium-ion secondary battery of the present embodiment, the binding agent, and the solvent is set to 100 parts by mass.

[0100]

When the content rate of the solvent in the cathode material
10 paste is in the above-described range, it is possible to obtain cathode material paste having excellent cathode formability and excellent battery characteristics.

[0101]

A method for mixing the cathode material for a lithium-ion
15 secondary battery of the present embodiment, the binding agent, the conductive auxiliary agent, and the solvent is not particularly limited as long as these components can be uniformly mixed together. Examples thereof include mixing methods in which a kneader such as a ball mill, a sand mill, a planetary
20 (sun-and-planet) mixer, a paint shaker, or a homogenizer is used.

[0102]

The cathode material paste is applied to one main surface of the electrode current collector so as to form a coated film, and then this coated film is dried, thereby obtaining the electrode
25 current collector having a coated film made of a mixture of the

cathode material and the binding agent formed on one main surface.

[0103]

After that, the coated film is pressed by pressure and is dried, thereby obtaining a cathode having the cathode mixture
5 layer on one main surface of the electrode current collector.

[0104]

Lithium-ion secondary battery

A lithium-ion secondary battery of the present embodiment includes a cathode, an anode, and a non-aqueous electrolyte,
10 in which the cathode is the cathode for a lithium-ion secondary battery of the present embodiment. Specifically, the lithium-ion secondary battery of the present embodiment includes the cathode for a lithium-ion secondary battery of the present embodiment as a cathode, an anode, a separator, and a non-aqueous
15 electrolyte.

[0105]

In the lithium-ion secondary battery of the present embodiment, the anode, the non-aqueous electrolyte, and the separator are not particularly limited.

20 [0106]

Anode

Examples of the anode include anodes including an anode material such as Li metal, carbon materials such as natural graphite and hard carbon, Li alloys, $\text{Li}_4\text{Ti}_5\text{O}_{12}$, $\text{Si}(\text{Li}_{4.4}\text{Si})$, and
25 the like.

[0107]

Non-aqueous electrolyte

Examples of the non-aqueous electrolyte include
non-aqueous electrolytes obtained by mixing ethylene carbonate
5 (EC) and ethyl methyl carbonate (EMC) so that the volume ratio
reaches 1:1 and dissolving lithium hexafluorophosphate (LiPF_6)
in the obtained solvent mixture so that the concentration reaches
1 mol/dm³.

[0108]

10 Separator

As the separator, it is possible to use, for example, porous
propylene.

[0109]

In addition, instead of the non-aqueous electrolyte and
15 the separator, a solid electrolyte may be used.

[0110]

Since the lithium-ion secondary battery of the present
embodiment includes the cathode for a lithium-ion secondary
battery of the present embodiment as the cathode, the lithium-ion
20 secondary battery has a high energy density and has excellent
input and output characteristics.

EXAMPLES

[0111]

Hereinafter, the present invention will be more
25 specifically described using examples and comparative examples,

but the present invention is not limited to the following examples.

[0112]

Example 1

Synthesis of cathode material for lithium-ion secondary
5 battery

Lithium phosphate (Li_3PO_4) (2 mol) and iron (II) sulfate
(FeSO_4) (2 mol) were added to and mixed with water so that the
total amount reached 4 L, thereby preparing a homogeneous
slurry-form mixture.

10 [0113]

Next, this mixture was stored in a pressure-resistant
airtight container having a capacity of 8 L and was hydrothermally
synthesized at 200°C for four hours, thereby generating a
precipitate.

15 [0114]

Next, this precipitate was cleaned with water, thereby
obtaining a cake-form precursor of a cathode active material.

[0115]

Next, a polyethylene glycol (20 g) was added as the organic
20 compound to the precursor of the cathode active material (150
g in terms of solid contents), and a dispersion treatment was
performed on a mixture thereof using zirconia balls having a
diameter of 5 mm as medium particles in a bead mill for two hours,
thereby preparing a homogeneous slurry.

25 [0116]

Next, this slurry was sprayed in the atmosphere at 200°C and dried, thereby obtaining agglomerates of the precursor of the cathode material which was coated with an organic substance having an average particle diameter of 8.5 μm.

5 [0117]

Next, the obtained dried powder (the agglomerates of the precursor of the cathode material) was calcinated in a nitrogen atmosphere for three hours at 700°C, thereby obtaining agglomerates having an average particle diameter of 8.5 μm.

10 [0118]

Cracking of agglomerates

The above-described agglomerates were cracked using a jet mill device (trade name: SJ-100, manufactured by Nisshin Engineering Inc.) under a condition of a supply rate of 200 g/hour, thereby obtaining a cathode material 1 of Example 1.

[0119]

Production of lithium-ion secondary battery

The cathode material 1, polyvinylidene fluoride (PVdF) as a binding agent, and acetylene black (AB) as a conductive auxiliary agent were added to N-methyl-2-pyrrolidone (NMP) which was a solvent so that the mass ratio (the cathode material 1:AB:PVdF) in paste reached 94:1:5, and the components were mixed together and kneaded using a kneader (trade name: THINKY MIXER, manufactured by Thinky Corporation) for 30 minutes under conditions of a revolution rate of 1,200 rpm and a rotation rate

of 800 rpm, thereby preparing cathode material paste (for the cathode).

[0120]

This cathode material paste (for the cathode) was applied
5 onto the surface of a 30 μm -thick aluminum foil (electrode current collector) so as to form a coated film, and the coated film was dried, thereby forming a cathode mixture layer on the surface of the aluminum foil.

[0121]

10 After that, the cathode mixture layer was pressed at a pressure of 58.84 MPa, thereby producing a cathode 1 of Example 1.

[0122]

A lithium metal was disposed as an anode with respect to
15 this cathode 1, and a separator made of porous polypropylene was disposed between the cathode 1 and the anode, thereby producing a member for a battery 1.

[0123]

Meanwhile, ethylene carbonate and diethyl carbonate were
20 mixed together in a mass ratio of 1:1, and furthermore, 1 mol/L of a LiPF_6 solution was added thereto, thereby producing an electrolyte solution 1 having lithium ion conductivity.

[0124]

Next, the member for a battery 1 was immersed in the
25 electrolyte solution 1, thereby producing a lithium-ion secondary

battery 1 of Example 1.

[0125]

Example 2

A cathode material 2 of Example 2 was obtained in the same
5 manner as in Example 1 except for the fact that the agglomerates
were cracked at a supply rate of 180 g/hour.

[0126]

A lithium-ion secondary battery 2 of Example 2 was produced
in the same manner as in Example 1 except for the fact that the
10 cathode material 2 was used.

[0127]

Example 3

A cathode material 3 of Example 3 was obtained in the same
manner as in Example 1 except for the fact that the agglomerates
15 were cracked at a supply rate of 150 g/hour.

[0128]

A lithium-ion secondary battery 3 of Example 3 was produced
in the same manner as in Example 1 except for the fact that the
cathode material 3 was used.

20 [0129]

Example 4

A cathode material 4 of Example 4 was obtained in the same
manner as in Example 1 except for the fact that the agglomerates
were cracked at a supply rate of 120 g/hour.

25 [0130]

A lithium-ion secondary battery 4 of Example 4 was produced in the same manner as in Example 1 except for the fact that the cathode material 4 was used.

[0131]

5 Example 5

A cathode material 5 of Example 5 was obtained in the same manner as in Example 1 except for the fact that the agglomerates were cracked at a supply rate of 100 g/hour.

[0132]

10 A lithium-ion secondary battery 5 of Example 5 was produced in the same manner as in Example 1 except for the fact that the cathode material 5 was used.

[0133]

Example 6

15 A cathode material 6 of Example 6 was obtained in the same manner as in Example 1 except for the fact that the agglomerates were cracked at a supply rate of 90 g/hour.

[0134]

20 A lithium-ion secondary battery 6 of Example 6 was produced in the same manner as in Example 1 except for the fact that the cathode material 6 was used.

[0135]

Example 7

25 Synthesis of cathode material for lithium-ion secondary battery

[0136]

Lithium phosphate (Li_3PO_4) (2 mol) and iron (II) sulfate (FeSO_4) (2 mol) were added to and mixed with water so that the total amount reached 4 L, thereby preparing a homogeneous
5 slurry-form mixture.

[0137]

Next, this mixture was stored in a pressure-resistant airtight container having a capacity of 8 L and was hydrothermally synthesized at 200°C for 24 hours, thereby generating a
10 precipitate.

[0138]

Next, this precipitate was cleaned with water, thereby obtaining a cake-form precursor of a cathode active material.

[0139]

15 Next, a polyethylene glycol (20 g) was added as the organic compound to the precursor of the cathode active material (150 g in terms of solid contents), and a dispersion treatment was performed on a mixture thereof using zirconia balls having a diameter of 5 mm as medium particles in a bead mill for two hours,
20 thereby preparing a homogeneous slurry.

[0140]

Next, this slurry was sprayed in the atmosphere at 200°C and dried, thereby obtaining agglomerates of the precursor of the cathode material which was coated with an organic substance
25 having an average particle diameter of $8.3\text{ }\mu\text{m}$.

[0141]

Next, the obtained dried powder (the agglomerates of the precursor of the cathode material) was calcinated in a nitrogen atmosphere for three hours at 700°C, thereby obtaining

5 agglomerates having an average particle diameter of 8.3 μm .

[0142]

Cracking of agglomerates

The above-described agglomerates were cracked using a jet mill device (trade name: SJ-100, manufactured by Nisshin Engineering Inc.) under a condition of a supply rate of 100 g/hour, thereby obtaining a cathode material 7 of Example 7.

[0143]

A lithium-ion secondary battery 7 of Example 7 was produced in the same manner as in Example 1 except for the fact that the cathode material 7 was used.

[0144]

Example 8

Synthesis of cathode material for lithium-ion secondary battery

20 [0145]

Lithium phosphate (Li_3PO_4) (2 mol) and iron (II) sulfate (FeSO_4) (2 mol) were added to and mixed with water so that the total amount reached 4 L, thereby preparing a homogeneous slurry-form mixture.

25 [0146]

Next, this mixture was stored in a pressure-resistant airtight container having a capacity of 8 L and was hydrothermally synthesized at 160°C for two hours, thereby generating a precipitate.

5 [0147]

Next, this precipitate was cleaned with water, thereby obtaining a cake-form precursor of a cathode active material.

[0148]

Next, a polyethylene glycol (20 g) was added as the organic
10 compound to the precursor of the cathode active material (150 g in terms of solid contents), and a dispersion treatment was performed on a mixture thereof using zirconia balls having a diameter of 5 mm as medium particles in a bead mill for two hours, thereby preparing a homogeneous slurry.

15 [0149]

Next, this slurry was sprayed in the atmosphere at 200°C and dried, thereby obtaining agglomerates of the precursor of the cathode material which was coated with an organic substance having an average particle diameter of 8.9 μm .

20 [0150]

Next, the obtained dried powder (the agglomerates of the precursor of the cathode material) was calcinated in a nitrogen atmosphere for three hours at 700°C, thereby obtaining agglomerates having an average particle diameter of 8.9 μm .

25 [0151]

Cracking of agglomerates

The above-described agglomerates were cracked using a jet mill device (trade name: SJ-100, manufactured by Nisshin Engineering Inc.) under a condition of a supply rate of 90 g/hour, thereby obtaining a cathode material 8 of Example 8.

[0152]

A lithium-ion secondary battery 8 of Example 8 was produced in the same manner as in Example 1 except for the fact that the cathode material 8 was used.

10 [0153]

Example 9

Synthesis of cathode material for lithium-ion secondary battery

Lithium phosphate (Li_3PO_4) (2 mol) and iron (II) sulfate (FeSO_4) (2 mol) were added to and mixed with water so that the total amount reached 4 L, thereby preparing a homogeneous slurry-form mixture.

[0154]

Next, this mixture was stored in a pressure-resistant airtight container having a capacity of 8 L and was hydrothermally synthesized at 120°C for five hours, thereby generating a precipitate.

[0155]

Next, this precipitate was cleaned with water, thereby obtaining a cake-form precursor of a cathode active material.

[0156]

Next, a polyethylene glycol (20 g) was added as the organic compound to the precursor of the cathode active material (150 g in terms of solid contents), and a dispersion treatment was performed on a mixture thereof using zirconia balls having a diameter of 5 mm as medium particles in a bead mill for two hours, thereby preparing a homogeneous slurry.

[0157]

Next, this slurry was sprayed in the atmosphere at 200°C and dried, thereby obtaining agglomerates of the precursor of the cathode material which was coated with an organic substance having an average particle diameter of 9.1 μm .

[0158]

Next, the obtained dried powder (the agglomerates of the precursor of the cathode material) was calcinated in a nitrogen atmosphere for three hours at 700°C, thereby obtaining agglomerates having an average particle diameter of 9.1 μm .

[0159]

Cracking of agglomerates

The above-described agglomerates were cracked using a jet mill device (trade name: SJ-100, manufactured by Nisshin Engineering Inc.) under a condition of a supply rate of 80 g/hour, thereby obtaining a cathode material 9 of Example 9.

[0160]

A lithium-ion secondary battery 9 of Example 9 was produced

in the same manner as in Example 1 except for the fact that the cathode material 9 was used.

[0161]

Comparative Example 1

5 A cathode material 10 of Comparative Example 1 was obtained in the same manner as in Example 1 except for the fact that the agglomerates were cracked at a supply rate of 280 g/hour.

[0162]

10 A lithium-ion secondary battery 10 of Comparative Example 1 was produced in the same manner as in Example 1 except for the fact that the cathode material 10 was used.

[0163]

Comparative Example 2

15 A cathode material 11 of Comparative Example 2 was obtained in the same manner as in Example 1 except for the fact that the agglomerates were cracked at a supply rate of 250 g/hour.

[0164]

20 A lithium-ion secondary battery 11 of Comparative Example 2 was produced in the same manner as in Example 1 except for the fact that the cathode material 11 was used.

[0165]

Comparative Example 3

25 A cathode material 12 of Comparative Example 3 was obtained in the same manner as in Example 1 except for the fact that the agglomerates were cracked at a supply rate of 70 g/hour.

[0166]

A lithium-ion secondary battery 12 of Comparative Example 3 was produced in the same manner as in Example 1 except for the fact that the cathode material 12 was used.

5 [0167]

Comparative Example 4

A cathode material 13 of Comparative Example 4 was obtained in the same manner as in Example 1 except for the fact that the agglomerates were cracked at a supply rate of 55 g/hour.

10 [0168]

A lithium-ion secondary battery 13 of Comparative Example 4 was produced in the same manner as in Example 1 except for the fact that the cathode material 13 was used.

[0169]

15 Comparative Example 5

A cathode material 14 of Comparative Example 5 was obtained in the same manner as in Example 8 except for the fact that the agglomerates were cracked at a supply rate of 65 g/hour.

[0170]

20 A lithium-ion secondary battery 14 of Comparative Example 5 was produced in the same manner as in Example 1 except for the fact that the cathode material 14 was used.

[0171]

Comparative Example 6

25 A cathode material 15 of Comparative Example 6 was obtained

in the same manner as in Example 9 except for the fact that the agglomerates were cracked at a supply rate of 55 g/hour.

[0172]

A lithium-ion secondary battery 15 of Comparative Example 5 6 was produced in the same manner as in Example 1 except for the fact that the cathode material 15 was used.

[0173]

Evaluation of cathode material for lithium-ion secondary battery and lithium-ion secondary battery

10 The cathode material for a lithium-ion secondary battery and the lithium-ion secondary batteries of Examples 1 to 9 and Comparative Examples 1 to 6 were evaluated as described below.

[0174]

1. Specific surface area

15 The BET specific surface area of the cathode material for a lithium-ion secondary battery was measured using a measurement device (trade name: HM model-1208, manufactured by Mountech Co., Ltd.) and a one-point method at a relative pressure of 0.29 (P/P_0).

[0175]

20 2. Amount of carbon

The amount of carbon in the cathode material for a lithium-ion secondary battery was measured using a carbon/sulfur analyzer (trade name: EMIA-220V, manufactured by Horiba Ltd.).

[0176]

25 3. Powder resistance value

The powder resistance value of the cathode material for a lithium-ion secondary battery was measured using a specimen produced by injecting the cathode material into a die and shaping the cathode material at a pressure of 50 MPa, a low resistivity meter (trade name: Loresta-GP, manufactured by Mitsubishi Chemical Corporation), and a four point measurement at 25°C.

[0177]

4. Median diameter

The median diameter of the cathode material for a lithium-ion secondary battery was measured using the following method.

[0178]

The median diameter was measured using a measurement device (trade name: LA-950V2, manufactured by Horiba Ltd.).

[0179]

First, pure water (40 g) and polyvinylpyrrolidone (PVP) (0.12 g) as a dispersion liquids and the cathode material for a lithium-ion secondary battery (0.04 g) as specimen powder were weighed in a 70 mL mayonnaise bottle. This mayonnaise bottle was manually shaken approximately ten times so as to mix the specimen powder and the dispersion liquids well.

[0180]

Next, the mixed solution of the specimen powder and the dispersion liquids was treated with ultrasonic waves for two minutes under conditions of output 5 and pulse 50% in an ultrasonic

homogenizer (trade name: SONIFIER450, manufactured by Branson Ultrasonics, Emersion Japan, Ltd.), and the median diameter was measured using the obtained dispersion solution. The median diameter refers to the particle diameter of a void for which the distribution curve of the integral percentage in the particle size distribution intersects the horizontal axis at 50% and was thus computed on the basis of the measurement results of the particle size distribution of the cathode material for a lithium-ion secondary battery.

10 [0181]

The median diameter was measured with the data loading number set to 5,000 in terms of a semiconductor laser (LD) and 1,000 in terms of a light-emitting diode (LED), and the data computation conditions were as described below.

15 Computation conditions

(Sample refractive index)

LD real part: 1.48

LD imaginary part: 0.45

LED real part: 1.50

20 LED imaginary part: 0.55

Dispersion medium refractive index

LD real part: 1.33

LD imaginary part: 0.00

LED real part: 1.33

25 LED imaginary part: 0.00

(Number of repetitions): 15 times

(Particle diameter criterion): Volume

(Computation algorithm): Standard computation

[0182]

5 5. Coarse particle ratio

The coarse particle ratio was computed from Expression (1) using the coarse particle-side peak area A and the fine particle-side peak area B in the particle size distribution of the cathode material for a lithium-ion secondary battery which had been obtained in the measurement of the median diameter.

$$\text{Coarse particle ratio (\%)} = A / (A + B) \times 100 \quad \dots \quad (1)$$

[0183]

6. Chromaticity b^*

The chromaticity b^* in the $L^*a^*b^*$ color space of the cathode material for a lithium-ion secondary battery was obtained by means of reflected light two-degree viewing angle measurement in which a spectroscopic calorimeter (Serial No.: SE-2000, manufactured by Nippon Denshoku Industries Co., Ltd.) and a D65 light source. When the chromaticity b^* of the cathode material for a lithium-ion secondary battery was measured, the cathode material of the measurement subject was evenly placed on a schale, and the chromaticity b^* of the cathode material was measured.

[0184]

7. Cathode density

The cathode density of the cathode material for a

lithium-ion secondary battery was computed as the ratio of the mass of the cathode material as the numerator to the volume of the cathode which was the compressed cathode excluding the aluminum electrode current collector as the denominator.

5 [0185]

In addition, in a case in which the cathode density was 2.00 g/cc or more, the cathode density was evaluated as A, in a case in which the cathode density was 1.90 g/cc or more, the cathode density was evaluated as B, and, in a case in which the
10 cathode density was less than 1.90 g/cc, the cathode density was evaluated as C.

[0186]

8. Capacity retention after 20 cycles

Regarding the capacity retention of the lithium-ion
15 secondary battery after 20 cycles, constant-current charging at a current value of 0.25 C until the battery voltage reached 3.7 V and then discharging at a current value of 0.5 C until the battery voltage reached 2.5 V in an environment of 45°C was considered as one cycle, this cycle was repeated 20 times, and
20 the fraction of the discharge capacity at the 20th cycle as the numerator to the discharge capacity at the first cycle as the denominator was evaluated as the capacity retention. In a case in which the electron conductivity of the cathode material was not sufficiently guaranteed, the active material particles
25 repeatedly expanded and shrank according to the charge and

discharge cycles, and thus the number of electron conduction paths in the cathode became insufficient, and thus the capacity retention decreased.

[0187]

5 In addition, in a case in which the capacity retention after 20 cycles was 70% or more, the electron conductivity was evaluated as B, and, in a case in which the capacity retention after 20 cycles was less than 70%, the electron conductivity was evaluated as C.

10 [0188]

Evaluation results

 The evaluation results of the cathode materials for a lithium-ion secondary battery and the lithium-ion secondary batteries of Examples 1 to 9 and Comparative Examples 1 to 6 are shown in Table 1. Meanwhile, the amount of carbon in Table 1 is the amount (parts by mass) of carbon forming the carbonaceous film with respect to 100 parts by mass of the cathode active material. In addition, the particle size distribution of the cathode material for a lithium-ion secondary battery of Example 20 1, which was obtained in order to compute the median diameter, is illustrated in FIG. 3. Similarly, the particle size distribution of the cathode material for a lithium-ion secondary battery of Comparative Example 3, which was obtained in order to compute the median diameter, is illustrated in FIG. 4.

25

[0189]

[Table 1]

	Agglomerate supply rate [g/hour]	Coarse particle ratio [%]	Specific surface area [m ² /g]	Amount of carbon [parts by mass]	Powder resistance value [Ω·cm]	Chromaticity b*	Median diameter [μm]	Cathode density [g/cc]	Cathode density evaluation	Capacity retention after 20 cycles [%]	Electron conductivity evaluation
Example 1	200	61	8.6	1.06	26	1.88	0.78	1.91	B	76	B
Example 2	180	58	8.6	1.06	30	1.91	0.74	1.93	B	75	B
Example 3	150	54	8.7	1.06	39	1.98	0.71	1.95	B	73	B
Example 4	120	46	8.6	1.06	45	2.08	0.67	1.99	B	73	B
Example 5	100	43	8.7	1.06	58	2.20	0.62	2.04	A	72	B
Example 6	90	41	8.7	1.06	60	2.22	0.59	2.06	A	72	B
Example 7	100	51	5.9	0.73	25	2.21	0.54	2.08	A	77	B
Example 8	90	46	15.5	1.91	78	2.26	0.63	1.99	B	72	B
Example 9	80	43	24.0	2.96	92	2.28	0.71	1.91	B	71	B
Comparative Example 1	280	71	8.4	1.06	10	1.82	0.85	1.81	C	77	B
Comparative Example 2	250	68	8.4	1.06	15	1.86	0.83	1.86	C	76	B
Comparative Example 3	70	33	8.8	1.06	111	2.35	0.55	2.10	A	66	C
Comparative Example 4	55	25	8.9	1.06	130	2.46	0.49	2.14	A	55	C
Comparative Example 5	65	31	15.8	1.91	351	2.35	0.52	2.02	A	64	C
Comparative Example 6	55	29	24.4	2.96	542	2.40	0.64	1.98	B	51	C

[0190]

When Examples 1 to 9 and Comparative Examples 1 to 6 are compared with one another using the results in Table 1, in Comparative Examples 1 and 2 in which the coarse particle ratios
5 exceeded 65%, cracking was not sufficient, and thus the cathode densities were as low as less than 1.90 g/cc, and the energy densities per unit volume were poor when the cathode materials for a lithium-ion secondary battery were used as cathode materials for a lithium-ion secondary batteries.

10 [0191]

In addition, in Comparative Examples 3 to 6 in which the coarse particle ratios were less than 35%, the cracking intensities were too high, and thus the carbonaceous films that coated the surfaces of the central particles were peeled off
15 during the cracking, the capacity retention after 20 cycles was as low as less than 70%, and the input and output characteristics and durability were poor when the cathode materials for a lithium-ion secondary battery were used as cathode materials for a lithium-ion secondary batteries.

20 [0192]

On the other hand, in Examples 1 to 9, since the coarse particle ratios were in a range of 35% or more and 65% or less, the cathode densities were 1.90 g/cc or more, the capacity retention after 20 cycles was in a range of 70% or more, excellent
25 battery characteristics were exhibited, and it was possible to

provide lithium-ion secondary batteries having excellent energy density, input and output characteristics, and durability in the case of being used as cathode materials for a lithium-ion secondary batteries.

5 [0193]

In addition, when Examples 6 to 9 and Comparative Examples 5 and 6 were compared with one another, it is also possible to confirm that, even when the specific surface area and the amount of carbon vary, as long as the cracking intensity is adjusted so that the coarse particle ratio becomes 35% or more and 65% or less, it is possible to develop excellent battery characteristics which are the cathode density reaching 1.9 g/cc or more and the capacity retention after 20 cycles reaching 70% or more.

15 [0194]

Lithium-ion secondary batteries for which the cathode material for a lithium-ion secondary battery of the present invention is used have an excellent energy density, input and output characteristics, and durability and are thus capable of significantly contributing to the advancement of the reliability of lithium-ion secondary batteries including mobile body applications.

AMENDED CLAIMS

1. A cathode material for a lithium-ion secondary battery which is active material
 5 particles including central particles represented by General Formula $\text{Li}_x\text{A}_y\text{D}_z\text{PO}_4$ in which $0.9 < x < 1.1$, $0 < y \leq 1$, $0 \leq z < 1$, and $0.9 < y + z < 1.1$, A represents at least one element selected from the group consisting of Co, Mn, Ni, Fe, Cu, and Cr, and D represents at least one element selected from the group consisting of Mg, Ca, Sr, Ba, Ti, Zn, B, Al, Ga, In, Si, Ge, Sc, and Y, and a carbonaceous film that coats surfaces of the central particles, wherein:

10 a particle size distribution of the active material particles measured by a laser diffraction and scattering particle size distribution measurement instrument has a peak of fine particles and a peak of coarse particles,

a maximum value of the peak of the fine particles in the particle size distribution of the active material particles is $0.15\text{ }\mu\text{m}$ or more and $0.35\text{ }\mu\text{m}$ or less, and a maximum value
 15 of the peak of the coarse particles is $0.80\text{ }\mu\text{m}$ or more and $1.20\text{ }\mu\text{m}$ or less,

a coarse particle ratio which is a ratio of an area surrounded by a curve indicating a peak shape of the coarse particles in the particle size distribution to the sum of the area surrounded by the curve indicating the peak shape of the coarse particles and an area surrounded by a curve indicating a peak shape of fine particles in the particle size
 20 distribution is 35% or more and 65% or less, and

a median diameter of the active material particles is $0.50\text{ }\mu\text{m}$ to $0.80\text{ }\mu\text{m}$.
2. The cathode material for the lithium-ion secondary battery according to claim 1,
 wherein a powder resistance value of the active material particles is $100\text{ }\Omega\cdot\text{cm}$ or less,
 25 the powder resistance value being measured using a specimen produced by injecting the cathode material into a die and shaping the cathode material at a pressure of 50 MPa, a low resistivity meter, and a four point measurement at 25°C .
3. The cathode material for the lithium-ion secondary battery according to claim 1 or 2,

wherein chromaticity b^* in an $L^*a^*b^*$ color space is 1.9 or more and 2.3 or less, the chromaticity b^* being obtained by means of reflected light two-degree viewing angle measurement in which a spectroscopic calorimeter and a D65 light source are used.

- 5 4. The cathode material for the lithium-ion secondary battery according to any one of claims 1 to 3,
 wherein a BET specific surface area is $5 \text{ m}^2/\text{g}$ or more and $25 \text{ m}^2/\text{g}$ or less, and an amount of carbon forming the carbonaceous film is 0.1 parts by mass or more and 10 parts by mass or less with respect to 100 parts by mass of the central particles.

10

5. A cathode for a lithium-ion secondary battery, comprising:
 an electrode current collector; and
 a cathode mixture layer formed on the electrode current collector,
 wherein the cathode mixture layer includes the cathode material for the lithium-ion
 15 secondary battery according to any one of claims 1 to 4.

6. A lithium-ion secondary battery comprising:
 the cathode for the lithium-ion secondary battery according to claim 5.
