Solar Cell Assembly

Field of Invention

The present invention relates to a solar cell assembly and the manufacture of the same, and particularly the invention relates to a solar cell assembly comprising a cooling substrate and a bonding pad for the attachment of a solar cell.

Background of the invention

Photovoltaic or solar cells are designed for converting the solar radiation to electrical current. In concentrator solar photovoltaic applications, the incoming sunlight is optically concentrated before it is directed to solar cells. For example, the incoming sunlight is received by a primary mirror that reflects the received radiation toward a secondary mirror that, in turn, reflects the radiation toward a solar cell, which converts the concentrated radiation to electrical current by the generation of electron-hole pairs in III-V semiconductor or single crystal silicon, for example.

The solar cell comprises a semiconductor integrated circuit die and therefore requires some manner of integrated circuit package or solar cell assembly wherein the solar cell is connected to one or more functional devices. The solar cell assembly (SCA) may particularly provide environmental protection, heat dissipation and electrical connectivity to the solar cell.

In the art, SCAs are manufactured on a continuous single substrate base or comprises multiple components that are electrically isolated from each other. A critical issue is the backside contacting of the solar cell with the substrate of the SCA. Conventionally, a continuous single substrate functioning as a cooling substrate is contacted to the backside of a solar cell by means of selective noble metal (e.g., gold) deposition that represents a tedious and time-consuming as well as expensive processing step.
The provision of a number of electrically isolating material elements results in poor thermal conductivity and, thus, an inefficient overall thermal connection of the solar cell. Moreover, provision of materials of different material characteristics implies higher expenses and a plurality of connection regions and, therefore, results in a significant deterioration of the (long-life) reliability of the manufactured SCA.

Thus, despite the recent engineering progress there is still a need for providing an SCA that shows reliable electric contacting, efficient thermal conductivity and resistance against aging without increasing costs and, moreover, taking into account production rationalization.

**Description of the Invention**

The present invention addresses the above-mentioned need and, accordingly, provides a method for the manufacture of a solar cell assembly (SCA) according to claim 1, comprising the steps of

- providing a solar cell and a bonding pad for bonding of the solar cell;

- providing a cooling substrate; and

- attaching the bonding pad to a surface of the cooling substrate by means of a thermally conductive adhesive means.

According to an embodiment and electrically contacting the bonding pad to the cooling substrate can be achieved by a bonding wire. In this application the term "bonding pad" is used in the general meaning of a flat surface of an electrically conductive material intended to make electrical contact with a device. Alternatively, the bonding pad can be attached to the surface of the cooling substrate by means of an adhesive means that is both thermally and electrically conductive. This alternative example for the inventive method may further comprise electrically contacting the bonding pad to
the cooling substrate by a bonding wire in order to obtain an improved electrical connection between the bonding pad and the cooling substrate.

The adhesive means may be provided in form of a solder, conductive adhesive, adhesive tape, glue etc. In a particular example, a glue or an adhesive tape made of epoxy containing aluminum oxide is used as the adhesive means.

According to the present invention there is no need for some additional electrical insulation layer provided between the bonding pad and the cooling substrate as it is necessary in the art. Electrical contacting of the bonding pad and the cooling substrate can reliably obtained by means of the adhesive means and by providing electrical contact by a bonding wire. In particular, with respect to SCAs of the art the overall number of Galvanic elements and the number of different processed materials, that result in the formation of Galvanic elements, can effectively be reduced according to the present invention.

Thus, according to the present invention the number of expensive materials for the contact area can be reduced and production costs can be kept low and good reliability and long lifetime of the SCA are guaranteed.

The above-described examples for the inventive method may further comprise forming a contacting surface on at least a part of the bonding pad, for example, in a rectangular shape, and attaching the solar cell to the contacting surface. The solar cell may be contacted to the contacting surface by means of a thermally and/or electrically conductive adhesive or solder. The contacting surface may comprise or consist of a plating of a noble metal (e.g., gold, silver) or a non-noble metal (e.g., copper, tin, nickel or nickel-phosphorous). In particular, an electro-plated layer of a noble metal (e.g., gold, silver) or a non-noble metal (e.g., copper, tin, nickel or nickel-phosphorous) can be provided as the contact surface.

The bonding pad in the above-described embodiments may be provided in a geometric shape that (in a top view) comprises a superposition of a tetragon and an octagon such that one of two parallel sides of the octagon that are equally sized and longer
than each of the other six sides of the octagon (that may be equally sized) is superposed with one of two equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon. The other one of the equally sized parallel sides of the tetragon does not lie within the shape of the octagon.

According to an alternative embodiment the bonding pad in the above-described embodiments may be provided in a geometric shape that (in a top view) comprises a superposition of two trapezoids (that can be isosceles trapezoids) and a tetragon wherein the longer one of the sides of the upper isosceles trapezoid that are perpendicular to the symmetry axis of the upper (isosceles) trapezoid is superposed on an upper side of the tetragon that is larger than that side (i.e., the longer one of the sides of the upper (isosceles) trapezoid that are perpendicular to the symmetry axis of the upper (isosceles) trapezoid) and the longer one of the sides of the lower (isosceles) trapezoid that are perpendicular to the symmetry axis of the lower (isosceles) trapezoid is superposed on the lower side of the tetragon that is larger than that side (the longer one of the sides of the lower (isosceles) trapezoid that are perpendicular to the symmetry axis of the lower (isosceles) trapezoid). The two (isosceles) trapezoids are superposed on the tetragon such that the smaller sides parallel to the ones superposed on the respective sides of the tetragon do not lie within the shape of the tetragon.

In alternative embodiments the bonding pad has a hexagonal or rectangular shape.

In all alternative embodiments the bonding pad is integrally formed in one single piece of these geometric shapes. Particular examples of the shapes are illustrated in Figures 3a and 3b as well as 6a and 6b.

It is also provided a solar cell assembly, comprising

a solar cell attached to a bonding pad;

a cooling substrate;
wherein the bonding pad is attached to a surface of the cooling substrate by means of a thermally conductive adhesive means. The bonding pad may be, furthermore, electrically contacted to the cooling substrate by a bonding wire.

According to an alternative embodiment it is provided a solar cell assembly, comprising

a solar cell attached to a bonding pad;

a cooling substrate;

wherein the bonding pad is attached to a surface of the cooling substrate by means of a thermally and electrically conductive adhesive means.

In this alternative embodiment the bonding pad may furthermore be electrically contacted to the cooling substrate by a bonding wire.

In the above-mentioned examples of the inventive solar cell the bonding pad may be provided in a geometric shape that comprises (in a top view)

a superposition of a tetragon, in particular, a rectangle, and an octagon such that one of two parallel sides of the octagon that are equally sized and longer than each of the other six sides of the octagon is superposed with one of two equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon;

or a superposition of two (isosceles) trapezoids and a tetragon wherein the longer one of the sides of the upper (isosceles) trapezoid that are perpendicular to the symmetry axis of the upper (isosceles) trapezoid is superposed on an upper side of the tetragon that is larger than that side and the longer one of the sides of the lower (isosceles) trapezoid that are perpendicular to the symmetry axis of the lower (isosceles) trapezoid is superposed on the lower side of the tetragon that is larger than that side.
Again, the other one of the equally sized parallel sides of the tetragon does not lie within the shape of the octagon and the two (isosceles) trapezoids are superposed on the tetragon such that the smaller sides parallel to the ones superposed on the respective sides of the tetragon do not lie within the shape of the tetragon.

The solar cell assembly may further comprise an electrical device, as for example, a bypass diode or any device with a conductive surface insulated against the cooling substrate, that is connected to a surface of the solar cell by wires and positioned on a region of the bonding pad or the cooling substrate.

The present invention, furthermore, provides a bonding pad for bonding a solar cell and suitable for connection with a cooling substrate, wherein the bonding pad shows the geometric shape (in a top view) of

a superposition of a tetragon, in particular, a rectangle, and an octagon such that one of two parallel sides of the octagon that are equally sized and longer than each of the other six sides of the octagon is superposed with one of two equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon;

or a superposition of two (isosceles) trapezoids and a tetragon wherein the longer one of the sides of the upper (isosceles) trapezoid that are perpendicular to the symmetry axis of the upper (isosceles) trapezoid is superposed on an upper side of the tetragon that is larger than that side and the longer one of the sides of the lower (isosceles) trapezoid that are perpendicular to the symmetry axis of the lower (isosceles) trapezoid is superposed on the lower side of the tetragon that is larger than that side.

Again, the other one of the equally sized parallel sides of the tetragon does not lie within the shape of the octagon and the two (isosceles) trapezoids are superposed on the tetragon such that the smaller sides parallel to the ones superposed on the respective sides of the tetragon do not lie within the shape of the tetragon.
Alternatively, the bonding pad may show the geometric shape of a hexagon or a rectangle.

The bonding pad may further comprise a contact surface for contacting the back side of a solar cell that is to be attached to the bonding pad, wherein the contact surface, in particular, consists of a plating of a noble metal (e.g., gold, silver) or a non-noble metal (e.g., copper, tin, nickel or nickel-phosphorous). In particular, an electro-plated layer of a noble metal (e.g., gold, silver) or a non-noble metal (e.g., copper, tin, nickel or nickel-phosphorous) can be provided as the contact surface.

In addition, it is provided a leadframe comprising a plurality of the above-described bonding pads, wherein the bonding pads are densely packed in one plane. In particular, the leadframe may comprise the arrangement of bonding pads as illustrated in Figure 5. Such a leadframe allows for very efficient processing by standard semiconductor technology.

In all of the above exemplary methods and devices the bonding pad and/or the cooling substrate may comprise or consist of an aluminum alloy, for example, of a 99.5 % aluminum alloy. In particular, a cooling substrate of a 99.5 % aluminum alloy and a bonding pad of a 99.5 % aluminum alloy and comprising a contacting surface with an uppermost silver layer for contacting the backside of the solar cell in combination with attachment of the bonding pad to the cooling substrate by an epoxy glue comprising aluminium oxide and electrically contacting the bonding pad with the cooling substrate by aluminium wiring represents a particularly cost-effective configuration when used in the above-described examples.

Additional features and advantages of the present invention will be described with reference to the drawings. In the description, reference is made to the accompanying figures that are meant to illustrate preferred embodiments of the invention. It is understood that such embodiments do not represent the full scope of the invention.

Figures 1a and 1b illustrate an example of an SCA comprising a cooling substrate, a bonding pad, a solar cell and an electrical device contacted with the solar cell according to the invention.
Figures 2a and 2b illustrates another example of an SCA comprising a cooling substrate, a bonding pad, a solar cell and an electrical device contacted with the solar cell according to the invention.

Figures 3a and 3b illustrate exemplary geometric shapes of bonding pads according to examples of the present invention.

Figure 4 illustrates thick-wire wiring of individual SCAs formed according to examples of the present invention.

Figure 5 illustrates a leadframe comprising bonding pads according to an example of the present invention.

Figures 6a and 6b illustrate further exemplary geometric shapes of bonding pads arranged in leadframes according to examples of the present invention.

An SCA configuration manufactured in accordance with the present invention is illustrated in Figures 1a (top view) and 1b (side view). According to the shown example, the SCA comprises a solar cell 1, a bonding pad 2, a separate electronic device 3 (for example, a bypass diode or any device with a conductive surface insulated against the cooling substrate) that is electrically contacted with the upper surface of the solar cell 1 by means of bonding wires 4 and a cooling substrate 5. It is noted that a pad, for example, an aluminium pad can be provided in place of the electronic device 3. It is preferred that the bonding pad 2 and the cooling substrate 5 are made of the same material. According to an example this material is an aluminum alloy, in particular, a 99.5% aluminum alloy. Thermal stresses and galvanic elements between the bonding pad 2 and the cooling substrate 5 are largely avoided by the choice of the same material.

In principle, the cooling substrate 5 consists of a plane metal and shall provide thermal cooling and may also serve as an electric conductor. The dimensions and, particularly,
the thickness of the plane metal (as the thickness of the bonding pad 2) can be selected in accordance with the desired cooling performance. The choice of a 99.5% aluminum alloy for the cooling substrate 5 allows for reliably contacting to thin-wire or thick-wire or ribbon bond connections as well as connecting to a secondary optics of a concentrator solar photovoltaic application made of aluminium.

The bonding pad 2 comprises a contact surface 6 covering completely or partly the bonding pad 2. The contact surface 6 consists of a material that is suitable for contacting the back side of the solar cell 1. For example, the contact surface 6 may consist of a plating of a noble metal (e.g., gold, silver) or a non-noble metal (e.g., copper, tin, nickel or nickel-phosphorous). In particular, an electro-plated layer of a noble metal (e.g., gold, silver) or a non-noble metal (e.g., copper, tin, nickel or nickel-phosphorous) can be provided as the contact surface 6. The contact surface can particularly be provided in a rectangular shape. Alternatively, the solar cell may be directly connected to the aluminium bonding pad 2. Furthermore, electrical contact between the bonding pad 2 and the cooling substrate 5 is provided by a bonding wire 7.

The bonding pad 2 is attached to the cooling substrate 5 by means of a thermally conductive adhesive means 9 (see Figure 1b). The adhesive means 9 can be a thermally conductive glue, solder or adhesive tape or foil, for example. The thermally conductive adhesive means 9 may also provide for electrical conductivity. However, in order to save manufacturing costs an electrically non-conducting adhesive means 9 may be provided, for instance, glue or an adhesive tape made of epoxy containing aluminum oxide. In this case, electrical connection can be provided by bond wiring 7, in particular, by means of an aluminum wire, as it is illustrated in Figures 1a and 1b.

The bonding pad 2 shows a geometric shape that facilitates thermal cooling and may comprise a portion that is appropriate for positioning a device 3, for example, a bypass diode or an electrically isolated contact pad, to be electrically contacted with the upper surface of the solar cell 1 by means of bonding wires 4. In the shown example (see Figure 1a) the bonding pad 2 has a shape of an octagon superimposed by a tetragon such that one of two parallel sides of the octagon that are equally sized and longer than each of the other six sides of the octagon is superposed with one of two
equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon.

Contacting of the solar cell 1 with the bonding pad 2 can be realized by means of a solder 8 or thermally and/or electrically conductive adhesive 8 as it is shown in Figure 1b. According to the present example, device 3 is similarly contacted by the solder 8 or conductive adhesive 8 to the bonding pad 2. A preferred example for the adhesive 8 is a silver glue for the case that the uppermost layer of the contact surface 6 comprises silver.

According to a particular embodiment at least one of the bonding pad 2 and the cooling substrate consists of a 99.5% aluminum alloy and the bonding pad 2 comprises a galvanic layer or plating with an exposed silver surface at the top. On the silver surface a conductive silver adhesive is formed for electrical and thermal connection with the backside of the solar cell 1. The same or a different conductive silver adhesive is used for the electrical and thermal connection of the bonding pad 2 and device 3.

Figures 2a and 2b illustrate another embodiment of an SCA comprising a cooling substrate, a bonding pad a solar cell and an electrical device contacted with the solar cell according to the invention. As compared to the example shown in Figures 1a and 1b the bonding pad 2 has a different shape and does not include a portion for positioning device 3 that is connected to the upper surface of the solar cell 1 by wires 4. The bonding pad shown in Figure 2a is shaped in the form of a polygon with twelve corners and sides. In detail, the shape of the bonding pad 2 is given by a superposition of two (isosceles) trapezoids and a tetragon. The longer one of the sides of the upper (isosceles) trapezoid that are perpendicular to the symmetry axis of the upper (isosceles) trapezoid is superposed on an upper side of the tetragon that is larger than that side. Similarly, the longer one of the sides of the lower (isosceles) trapezoid that are perpendicular to the symmetry axis of the lower (isosceles) trapezoid is superposed on the lower side of the tetragon (parallel to the upper side of the tetragon) that is larger than that side (see Figure 2a).
As in the example described with reference to Figures 1a and 1b, the bonding pad 2 comprises a contact surface 6 covering partly the bonding pad 2. The contact surface 6 is shaped rectangular and consists of a material that is suitable for contacting the back side of the solar cell 1, for example, gold, silver, copper, tin, nickel or nickel-phosphorous. The solar cell 1 is contacted with the bonding pad via a solder 8 or thermally and/or electrically conductive adhesive 7. The device 3 is positioned spaced apart from the bonding pad 2 and it is contacted with the cooling substrate 5 via another solder 8 or a thermally and/or electrically conductive adhesive 8 of the same or a different material as the one used for contacting the solar cell 1 with the bonding pad 2 (Figure 2b).

Individual SCAs according to the examples of Figures 1a and 1b or Figures 2a and 2b can be wired as it is shown in Figure 4. Thick-wires 9, for example, aluminium wires, connect to the bonding pads 2 of the SCAs. A secondary optics or its mount made of aluminum can readily be connected to the cooling substrate 5 by means of laser welding, etc.

Fabrication of the bonding pads can be realized, for example, as follows. Rectangular pieces of aluminum (or a different metal) are provided. Stripes of noble or non-noble metal are formed on this rectangular piece of aluminum to form the future contact surfaces. Then the bonding pads are formed by stamping, to form a so called leadframe 10 shown in Figure 5. The position and shape of the pad are designed such that a very high density of bonding pad can be arranged on a single rectangular piece of aluminium, such that a single stamping step is sufficient to form the pad. Also, the bonding pads are designed and positioned such that the continuous stripes of noble or non-noble metal coated on the surface of the aluminium piece are appropriately positioned on the pad, after stamping, for receiving the solar cell and possibly the diode.

The assembling of the bonding pad, the cooling substrate and the solar cell may comprise the following. The solar cells and possibly the diode are successively assembled on the bonding pad being part of the leadframe. Then each bonding pad of the leadframe is "detached" and joined/attached to the cooling substrate. This is very preferable in term of manufacturability, since the small elements (diode, solar cells) are
picked and placed on the leadframe. This procedure can be performed in an automated industrial way with current equipment. However, care should be taken not to deteriorate those electronic components during the assembly of the bond pad with the cooling substrate. In this procedure there is a need to pick and place the bond pad with their electronic component mounted on them. Therefore the bond pad should exhibit some "handling area" that typically is not coated with a noble or non-noble metal. The handling area will allow the "pick and place" tool to manipulate the bond pad.

By the areas defined by the sides indicated by e and g and by f and g of Figure 3a as well as by the trapezoid areas of Figure 3b handling areas defined. Moreover, the handling area is helpful since it put some distance between the devices (solar cell, diode) with the contour of the bond pad that can exhibit a high temperature during the assembling step with the cooling substrate.

In the present invention bonding pads 2 of particular geometric shapes are provided as it is also illustrated in Figures 3a and 3b. The bonding pads 2 provided by the present invention are particularly suitable for mass production and processing by semiconductor technology. In Figure 5 a leadframe comprising a plurality bonding pads 2 is illustrated. The bonding pads are densely and planar packed on a metal stripe 10 that can be promoted in a production line. In the shown example a plurality of bonding pads 2 described with reference to Figures 1a and 1b and as shown in Figure 3a form the leadframe. The uppermost and lowermost bonding pads 2 and the leftmost and rightmost bonding pads 2 of Figure 5 may be designated as boundary bonding pads. All bonding pads that are completely neighboured by other bonding pads are designated as inner bonding pads.

The inner bonding pads are arranged such that for each of these bonding pads I the following holds:

A) A long side (indicated by a in Figure 3) of the rectangle of the bonding pad I (being parallel to a long side of the octagon of the same bonding pad) is positioned adjacent to a long side of the octagon of a first other bonding pad II and a long side (indicated
by b in Figure 3a) of the octagon of the same bonding pad I is positioned adjacent to a long side of the rectangle of second other bonding pad III.

B) A first short side (shorter than the long side and indicated by c in Figure 3a) of the rectangle of the bonding pad I is positioned adjacent to a first short side of an octagon of a third other bonding pad IV and a second short side (indicated by d in Figure 3a) parallel to the first short side of the rectangle of the bonding pad I is positioned adjacent to a first short side of an octagon of a fourth other bonding pad V.

C) A first short side (shorter than the long side and indicated by e in Figure 3a) of the octagon of the bonding pad I is positioned adjacent to a first short side of the rectangle of a fifth other bonding pad VI and a second short side (parallel to the first one and indicated by f in Figure 3a)) of the octagon of the bonding pad I is positioned adjacent to a first short side of the rectangle of a sixth other bonding pad VII.

D) The diagonal sides (indicated by g in Figure 3a) of the octagon of the bonding pad I are adjacent to respective diagonal sides of the third to sixth octagons IV to VII as shown in Figure 5.

In a similar manner the bonding pads described with reference to Figures 2a and 2b and as shown in Figure 3b can be arranged in a dense arrangement. In a particular arrangement, diagonal sides of one bonding pad 2 illustrated in Figure 3b are positioned adjacent to diagonal sides of other bonding pads 2 of the same shape in a leadframe comprising the bonding pads 2 shown in Figure 3b.

Whereas particular geometric shapes of the bonding pad 2 and the corresponding arrangement of the same in a leadframe are described above, the inventive bonding pads 2 are not restricted to that.

Further alternative appropriate shapes of the inventive bonding pad 2 and arrangements of the same in a leadframe are illustrated in Figures 6a and 6b. Compared with the geometric shapes of the above-described bonding pads the shapes of the bonding pads shown in Figures 6a (hexagon) and 6b (two rectangles) are simpler. No particu-
lar handling area is defined. In this case, the dimensions of the bonding pad can be reduced and manufacture of the bonding pad is cheaper. Such bonding pads are particularly useful for the following procedure of assembling the bonding pad, the cooling substrate and the solar cell. In a first step, the bonding pad is assembled on the cooling substrate. In a second step, the solar cell and possibly the diode are connected to the bonding pad. However, the manufacture is less easy (in terms of automation) as compared to the above-described method of assembly, because the devices are to be positioned on rather large substrates (cooling substrate and bonding pad).

All previously discussed embodiments are not intended as limitations but serve as examples illustrating features and advantages of the invention. It is to be understood that some or all of the above described features can also be combined in different ways.
Claims

1. Method for the manufacture of a solar cell assembly, comprising

   providing a solar cell (1) and a bonding pad (2) for bonding of the solar cell (1);

   providing a cooling substrate (5); and

   attaching the bonding pad (2) to a surface of the cooling substrate (5) by means of a thermally conductive adhesive means (9), in particular, by a glue or an adhesive tape made of epoxy containing aluminum oxide.

2. The method according to claim 1, further comprising electrically contacting the bonding pad (2) to the cooling substrate (5) by a bonding wire (7).

3. The method according to claim 1, wherein the bonding pad (2) is attached to the surface of the cooling substrate (5) by means of a thermally and electrically conductive adhesive means (9).

4. The method according to claim 3, further comprising electrically contacting the bonding pad (2) to the cooling substrate (5) by a bonding wire (7).

5. The method according to one of the preceding claims, further comprising forming a contacting surface (6) on at least a part of the bonding pad (2) and attaching the solar cell (1) to the contacting surface (6).

6. The method according to claim 5, wherein the solar cell (1) is contacted to the contacting surface (6) by means of a thermally and/or electrically conductive adhesive (8) or solder (8), in particular, by a silver glue.

7. The method according to one of the preceding claims, wherein the bonding pad (2) is provided in a geometric shape that
either comprises a superposition of a tetragon, in particular, a rectangle, and an octagon such that one of two parallel sides of the octagon that are equally sized and longer than each of the other six sides of the octagon is superposed with one of two equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon;

or a superposition of two trapezoid, in particular, isosceles trapezoids, and a tetragon wherein the longer one of the sides of the upper trapezoid that are perpendicular to the symmetry axis of the upper trapezoid is superposed on an upper side of the tetragon that is larger than that side and the longer one of the sides of the lower trapezoid that are perpendicular to the symmetry axis of the lower trapezoid is superposed on the lower side of the tetragon that is larger than that side;

or the bonding pad is provided in a geometric shape given by a hexagon or rectangle.

8. A solar cell assembly, comprising

a solar cell (1) attached to a bonding pad (2);

a cooling substrate (5);

wherein the bonding pad (2) is attached to a surface of the cooling substrate (5) by means of a thermally conductive adhesive means (9)

9. The solar cell assembly according to claim 8, wherein the bonding pad (2) is electrically contacted to the cooling substrate (5) by a bonding wire (7).

10. The solar cell assembly according to claim 8, wherein the bonding pad (2) is attached to a surface of the cooling substrate (5) by means of a thermally and electrically conductive adhesive means (9).
11. The solar cell assembly according to claim 10, wherein the bonding pad is electrically contacted to the cooling substrate (5) by a bonding wire (7).

12. The solar cell assembly according to one of the claims 7 to 9, wherein the bonding pad (2) is provided in a geometric shape that comprises

a superposition of a tetragon, in particular, a rectangle, and an octagon such that one of two parallel sides of the octagon that are equally sized and longer than each of the other six sides of the octagon is superposed with one of two equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon;

or a superposition of two isosceles trapezoids and a tetragon wherein the longer one of the sides of the upper isosceles trapezoid that are perpendicular to the symmetry axis of the upper isosceles trapezoid is superposed on an upper side of the tetragon that is larger than that side and the longer one of the sides of the lower isosceles trapezoid that are perpendicular to the symmetry axis of the lower isosceles trapezoid is superposed on the lower side of the tetragon that is larger than that side;

or the bonding pad is provided in a geometric shape given by a hexagon or rectangle.

13. A bonding pad (2) for bonding a solar cell (1) and suitable for connection with a cooling substrate (5), wherein the bonding pad (2) shows the geometric shape of

a superposition of a tetragon, in particular, a rectangle, and an octagon such that one of two parallel sides of the octagon that are equally sized and longer than each of the other six sides of the octagon is superposed with one of two equally sized parallel sides of the tetragon that are longer than the other two parallel equally sized sides of the tetragon;
or a superposition of two isosceles trapezoids and a tetragon wherein the longer one of the sides of the upper isosceles trapezoid that are perpendicular to the symmetry axis of the upper isosceles trapezoid is superposed on an upper side of the tetragon that is larger than that side and the longer one of the sides of the lower isosceles trapezoid that are perpendicular to the symmetry axis of the lower isosceles trapezoid is superposed on the lower side of the tetragon that is larger than that side;

or a hexagon or a rectangle.

14. The bonding pad (2) according to claim 12 and further comprising a contact surface (6) for contacting the back side of a solar cell (1) that is to be attached to the bonding pad (2), wherein the contact surface (6), in particular, consists of a plating of a noble metal, in particular, gold or silver, or a non-noble metal, in particular, copper, tin, nickel or nickel-phosphorous) an, in particular, an electro-plated layer of a noble metal or a non-noble metal.

15. A leadframe comprising a plurality of bonding pads (2) according to claim 12 or 13, wherein the bonding pads (2) are densely packed in one plane.

See patent family annex.

* Special categories of cited documents:
  * "A": document defining the general state of the art which is not considered to be of particular relevance
  * "E": earlier document but published on or after the international filing date
  * "L": document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
  * "O": document referring to an oral disclosure, use, exhibition or other means
  * "P": document published prior to the international filing date but later than the priority date claimed

* "T": later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

* "X": document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is taken alone

* "Y": document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

* "A": document member of the same patent family

---

Date of the actual completion of the international search: 27 June 2011  
Date of mailing of the international search report: 01/07/2011

Name and mailing address of the ISA/  
European Patent Office, P.B. 5818 Patentlaan 2  
NL - 2280 HV Rijswijk  
Tel. (+31-70) 340-2040,  
Fax. (+31-70) 340-3016

Authorized officer: Favre, Pierre

Form PCT/ISA/210 (second sheet) (April 2005)
