Title: DISAMBIGUATION OF WORDS CONTAINING LETTERS AND SYMBOLS

Abstract: A handheld electronic device includes a reduced QWERTY keyboard and is enabled with text disambiguation software. The device provides output in the form of a default output and a number of variants. The output is based largely upon the frequency, i.e., the likelihood that a user intended a particular output, but various features of the device provide additional variants that are not based solely on frequency and rather are provided by various logic structures resident on the device. The device includes a number of non-alphabetic characters that are assigned to keys and that can be accessed directly by the text disambiguation software without the need to activate a non-alphabetic input routine or to additionally actuate and <SHIFT> key or an <ALT> key, for instance.

DISAMBIGUATION OF WORDS CONTAINING LETTERS AND SYMBOLS

BACKGROUND

Field

The disclosed and claimed concept relates generally to handheld electronic devices and, more particularly, to a handheld electronic device having a reduced keyboard and a text disambiguation function that enable the outputting of non-alphabetic characters.

Background Information

Numerous types of handheld electronic devices are known. Examples of such handheld electronic devices include, for instance, personal data assistants (PDAs), handheld computers, two-way pagers, cellular telephones, and the like. Many handheld electronic devices also feature wireless communication capability, although many such handheld electronic devices are stand-alone devices that are functional without communication with other devices.

Such handheld electronic devices are generally intended to be portable, and thus are of a relatively compact configuration in which keys and other input structures often perform multiple functions under certain circumstances or may otherwise have multiple aspects or features assigned thereto. With advances in technology, handheld electronic devices are built to have progressively smaller form factors yet have progressively greater numbers of applications and features resident thereon. As a practical matter, the keys of a keypad can only be reduced to a certain small size before the keys become relatively unusable. In order to enable text entry, however, a keypad must be capable of entering all twenty-six letters of the Latin alphabet, for instance, as well as appropriate punctuation and other symbols.

One way of providing numerous letters, digits, and symbols in a small space has been to provide a "reduced keyboard" in which multiple letters, digits, and/or symbols , and the like, are assigned to any given key. For example, a touch-tone telephone includes a reduced keypad by providing twelve keys, of which ten have digits thereon, and of these ten keys eight have Latin letters assigned thereto. For instance, one of the keys includes the digit "2" as well
as the letters "A", "B", and "C". Other known reduced keyboards have included other arrangements of keys, letters, symbols, digits, and the like. Since a single actuation of such a key potentially could be intended by the user to refer to any of the letters "A", "B", and "C", and potentially could also be intended to refer to the digit "2", the input generally is an ambiguous input and is in need of some type of disambiguation in order to be useful for text entry purposes.

In order to enable a user to make use of the multiple letters, digits, symbols, and the like assigned to any given key, numerous keystroke interpretation systems have been provided. For instance, a "multi-tap" system allows a user to substantially unambiguously specify a particular character on a key by pressing the same key a number of times equivalent to the position of the desired character on the key. For example, on the aforementioned telephone key that includes the letters "ABC", and the user desires to specify the letter "C", the user will press the key three times. While such multi-tap systems have been generally effective for their intended purposes, they nevertheless can require a relatively large number of key inputs compared with the number of characters that ultimately are output.

Another exemplary keystroke interpretation system would include key chording, of which various types exist. For instance, a particular character can be entered by pressing two keys in succession or by pressing and holding first key while pressing a second key. Still another exemplary keystroke interpretation system would be a "press-and-hold / press-and-release" interpretation function in which a given key provides a first result if the key is pressed and immediately released, and provides a second result if the key is pressed and held for a short period of time. While they systems have likewise been generally effective for their intended purposes, such systems also have their own unique drawbacks.

Another keystroke interpretation system that has been employed is a software-based text disambiguation function. In such a system, a user typically presses keys to which one or more characters have been assigned, generally pressing each key one time for each desired letter, and the disambiguation software attempt to predict the intended input. Numerous such systems have been proposed, and while many have been generally effective for their intended purposes, shortcomings still exist.
Specifically, previous software-based text disambiguation functions provide disambiguated text interpretations of inputs, i.e., the processing of an ambiguous input by a software-based text disambiguation function results in textual output. As mentioned above, however, many keys have both alphabetic characters, i.e., letters, as well as non-alphabetic characters such as digits, symbols, and the like. It thus would be desirable to provide a software-based text disambiguation function that facilitates the output of non-alphabetic characters.
BRIEF DESCRIPTION OF THE DRAWINGS

A full understanding of the disclosed and claimed concept can be gained from the following Description when read in conjunction with the accompanying drawings in which:

DESCRIPTION

An improved handheld electronic device 4 is indicated generally in Fig. 1 and is depicted schematically in Fig. 2. The exemplary handheld electronic device 4 includes a housing 6 upon which are disposed a processor unit that includes an input apparatus 8, an output apparatus 12, a processor 16, a memory 20, and at least a first routine. The processor and the memory 20 can be said to together form a processor apparatus. The processor 16 may be, for instance, and without limitation, a microprocessor (μP) and is responsive to inputs from the input apparatus 8 and provides output signals to the output apparatus 12. The processor 16 also interfaces with the memory 20. Examples of handheld electronic devices are included in U.S. Patent Nos. 6,452,588 and 6,489,950, which are incorporated by reference herein.
As can be understood from Fig. 1, the input apparatus 8 includes a keypad 24 and a thumbwheel 32. As will be described in greater detail below, the keypad 24 is in the exemplary form of a reduced QWERTY keyboard including a plurality of keys 28 that serve as input members. It is noted, however, that the keypad 24 may be of other configurations, such as an AZERTY keyboard, a QWERTZ keyboard, or other keyboard arrangement, whether presently known or unknown, and either reduced or not reduced. In this regard, the expression "reduced" and variations thereof, in the context of a keyboard, a keypad, or other arrangement of input members, shall refer broadly to an arrangement in which at least one of the input members has assigned thereto a plurality of characters within a given set, such as a plurality of letters, for example, in the set of Latin letters, for example, thereby rendering ambiguous an intended result of an actuation of the at least one of the input members.

In this regard, and as will be set forth below in greater detail, the system architecture of the handheld electronic device 4 advantageously is organized to be operable independent of the specific layout of the keypad 24. Accordingly, the system architecture of the handheld electronic device 4 can be employed in conjunction with virtually any keypad layout substantially without requiring any meaningful change in the system architecture. It is further noted that certain of the features set forth herein are usable on either or both of a reduced keyboard and a non-reduced keyboard.

The keys 28 are disposed on a front face of the housing 6, and the thumbwheel 32 is disposed at a side of the housing 6. The thumbwheel 32 can serve as another input member and is both rotatable, as is indicated by the arrow 34, to provide selection inputs to the processor 16, and also can be pressed in a direction generally toward the housing 6, as is indicated by the arrow 38, to provide another selection input to the processor 16.

Among the keys 28 of the keypad 24 are a <NEXT> key 40 and an <ENTER> key 44. The <NEXT> key 40 can be pressed to provide a selection input to the processor 16 and provides substantially the same selection input as is provided by a rotational input of the thumbwheel 32. Since the <NEXT> key 40 is provided adjacent a number of the other keys 28 of the keypad 24, the user can provide a selection input to the processor 16 substantially without moving the user's hands away from the keypad 24 during a text entry operation. As will be described in greater detail below, the <NEXT> key 40 additionally and
advantageously includes a graphic 42 disposed thereon, and in certain circumstances the
output apparatus 12 also displays a displayed graphic 46 thereon to identify the <NEXT> key
40 as being able to provide a selection input to the processor 16. In this regard, the displayed
graphic 46 of the output apparatus 12 is substantially similar to the graphic 42 on the
<NEXT> key and thus identifies the <NEXT> key 40 as being capable of providing a
desirable selection input to the processor 16.

As can further be seen in Fig. 1, many of the keys 28 include a number of characters
48 disposed thereon. As employed herein, the expression "a number of" and variations
thereof shall refer broadly to any quantity, including a quantity of one. In the exemplary
depiction of the keypad 24, many of the keys 28 have assigned thereto at least two characters,
such as including a first alphabetic character 52 and a second alphabetic character 56 assigned
thereto. Some of the keys 28 additionally have assigned thereto one or more non-alphabetic
characters such as a numeric character 53 and/or a symbol character 55. It is understood that
the expression "symbol" shall broadly be construed herein to include punctuation marks such
as the period (.), the exclamation point (!), the question mark (?), the apostrophe ('), the
comma (,), and the like without limitation, and other marks such as the ampersand (&), the
dash (-), the plus (+), and the like without limitation, it being generally understood that a
symbol character typically will be a character that is non-alphabetic and non-numeric,
although exceptions to this rule are possible.

One of the keys 28 of the keypad 24 includes as the characters 48 thereof the letters
"Q" and "W", and an adjacent key 28 includes as the characters 48 thereof the letters "E" and
"R". It can be seen that the arrangement of the characters 48 on the keys 28 of the keypad 24
is generally of a QWERTY arrangement, albeit with many of the keys 28 including two of the
characters 48.

The output apparatus 12 includes a display 60 upon which can be provided an output
64. An exemplary output 64 is depicted on the display 60 in Fig. 1. The output 64 includes a
text component 68 and a variant component 72. The variant component 72 includes a default
portion 76 and a variant portion 80. The display also includes a caret 84 that depicts generally
where the next input from the input apparatus 8 will be received.
The text component 68 of the output 64 provides a depiction of the default portion 76 of the output 64 at a location on the display 60 where the text is being input. The variant component 72 is disposed generally in the vicinity of the text component 68 and provides, in addition to the default proposed output 76, a depiction of the various alternate text choices, i.e., alternates to the default proposed output 76, that are proposed by an input disambiguation function in response to an input sequence of key actuations of the keys 28.

As will be described in greater detail below, the default portion 76 is proposed by the disambiguation function as being the most likely disambiguated interpretation of the ambiguous input provided by the user. The variant portion 80 includes a predetermined quantity of alternate proposed interpretations of the same ambiguous input from which the user can select, if desired. The displayed graphic 46 typically is provided in the variant component 72 in the vicinity of the variant portion 80, although it is understood that the displayed graphic 46 could be provided in other locations and in other fashions without departing from the disclosed and claimed concept. It is also noted that the exemplary variant portion 80 is depicted herein as extending vertically below the default portion 76, but it is understood that numerous other arrangements could be provided without departing from the disclosed and claimed concept.

Among the keys 28 of the keypad 24 additionally is a <DELETE> key 86 that can be provided to delete a text entry. As will be described in greater detail below, the <DELETE> key 86 can also be employed in providing an alternation input to the processor 16 for use by the disambiguation function.

The memory 20 is depicted schematically in Fig. 2A. The memory 20 can be said to constitute a machine-readable medium and can be any of a variety of types of internal and/or external storage media such as, without limitation, RAM, ROM, EPROM(s), EEPROM(s), and the like that provide a storage register for data storage such as in the fashion of an internal storage area of a computer, and can be volatile memory or nonvolatile memory. The memory 20 additionally includes a number of routines depicted generally with the numeral 22 for the processing of data. The routines 22 can be in any of a variety of forms such as, without limitation, software, firmware, and the like. As will be explained in greater detail below, the
routines 22 include the aforementioned disambiguation function as an application, as well as other routines.

As can be understood from Fig. 2A, the memory 20 additionally includes data stored and/or organized in a number of tables, sets, lists, and/or otherwise. Specifically, the memory 20 includes a generic word list 88, a new words database 92, and a frequency learning database 96. Stored within the various areas of the memory 20 are a number of language objects 100 and frequency objects 104. The language objects 100 generally are each associated with an associated frequency object 104. The language objects 100 include a plurality of word objects 108 and a plurality of N-gram objects 112. The word objects 108 are generally representative of complete words within the language or custom words stored in the memory 20. For instance, if the language stored in the memory is, for example, English, generally each word object 108 would represent a word in the English language or would represent a custom word.

Associated with substantially each word object 108 is a frequency object 104 having frequency value that is indicative of the relative frequency within the relevant language of the given word represented by the word object 108. In this regard, the generic word list 88 includes a corpus of word objects 108 and associated frequency objects 104 that together are representative of a wide variety of words and their relative frequency within a given vernacular of, for instance, a given language. The generic word list 88 can be derived in any of a wide variety of fashions, such as by analyzing numerous texts and other language sources to determine the various words within the language sources as well as their relative probabilities, i.e., relative frequencies, of occurrences of the various words within the language sources.

The N-gram objects 112 stored within the generic word list 88 are short strings of characters within the relevant language typically, for example, one to three characters in length, and typically represent word fragments within the relevant language, although certain of the N-gram objects 112 additionally can themselves be words. However, to the extent that an N-gram object 112 also is a word within the relevant language, the same word likely would be separately stored as a word object 108 within the generic word list 88. As employed herein, the expression “string” and variations thereof shall refer broadly to an object having
one or more characters or components, and can refer to any of a complete word, a fragment of a word, a custom word or expression, and the like.

In the present exemplary embodiment of the handheld electronic device 4, the N-gram objects 112 include 1-gram objects, i.e., string objects that are one character in length, 2-gram objects, i.e., string objects that are two characters in length, and 3-gram objects, i.e., string objects that are three characters in length, all of which are collectively referred to as N-grams 112. Substantially each N-gram object 112 in the generic word list 88 is similarly associated with an associated frequency object 104 stored within the generic word list 88, but the frequency object 104 associated with a given N-gram object 112 has a frequency value that indicates the relative probability that the character string represented by the particular N-gram object 112 exists at any location within any word of the relevant language. The N-gram objects 112 and the associated frequency objects 104 are a part of the corpus of the generic word list 88 and are obtained in a fashion similar to the way in which the word object 108 and the associated frequency objects 104 are obtained, although the analysis performed in obtaining the N-gram objects 112 will be slightly different because it will involve analysis of the various character strings within the various words instead of relying primarily on the relative occurrence of a given word.

The present exemplary embodiment of the handheld electronic device 4, with its exemplary language being the English language, includes twenty-six 1-gram N-gram objects 112, i.e., one 1-gram object for each of the twenty-six letters in the Latin alphabet upon which the English language is based, and further includes 676 2-gram N-gram objects 112, i.e., twenty-six squared, representing each two-letter permutation of the twenty-six letters within the Latin alphabet.

The N-gram objects 112 also include a certain quantity of 3-gram N-gram objects 112, primarily those that have a relatively high frequency within the relevant language. The exemplary embodiment of the handheld electronic device 4 includes fewer than all of the three-letter permutations of the twenty-six letters of the Latin alphabet due to considerations of data storage size, and also because the 2-gram N-gram objects 112 can already provide a meaningful amount of information regarding the relevant language. As will be set forth in greater detail below, the N-gram objects 112 and their associated frequency objects 104
provide frequency data that can be attributed to character strings for which a corresponding word object 108 cannot be identified or has not been identified, and typically is employed as a fallback data source, although this need not be exclusively the case.

In the present exemplary embodiment, the language objects 100 and the frequency objects 104 are maintained substantially inviolate in the generic word list 88, meaning that the basic language corpus remains substantially unaltered within the generic word list 88, and the learning functions that are provided by the handheld electronic device 4 and that are described below operate in conjunction with other object that are generally stored elsewhere in memory 20, such as, for example, in the new words database 92 and the frequency learning database 96.

The new words database 92 and the frequency learning database 96 store additional word objects 108 and associated frequency objects 104 in order to provide to a user a customized experience in which words and the like that are used relatively more frequently by a user will be associated with relatively higher frequency values than might otherwise be reflected in the generic word list 88. More particularly, the new words database 92 includes word objects 108 that are user-defined and that generally are not found among the word objects 108 of the generic word list 88. Each word object 108 in the new words database 92 has associated therewith an associated frequency object 104 that is also stored in the new words database 92. The frequency learning database 96 stores word objects 108 and associated frequency objects 104 that are indicative of relatively more frequent usage of such words by a user than would be reflected in the generic word list 88. As such, the new words database 92 and the frequency learning database 96 provide two learning functions, that is, they together provide the ability to learn new words as well the ability to learn altered frequency values for known words.

Figs. 3A and 3B depict in an exemplary fashion the general operation of certain aspects of the disambiguation function of the handheld electronic device 4. Additional features, functions, and the like are depicted and described elsewhere.

An input is detected, as at 204, and the input can be any type of actuation or other operation as to any portion of the input apparatus 8. A typical input would include, for
instance, an actuation of a key 28 having a number of characters 48 thereon, or any other type of actuation or manipulation of the input apparatus 8.

Upon detection at 204 of an input, a timer is reset at 208. The use of the timer will be described in greater detail below.

The disambiguation function then determines, as at 212, whether the current input is an operational input, such as a selection input, a delimiter input, a movement input, an alternation input, or, for instance, any other input that does not constitute an actuation of a key 28 having a number of characters 48 thereon. If the input is determined at 212 to not be an operational input, processing continues at 216 by adding the input to the current input sequence which may or may not already include an input.

Many of the inputs detected at 204 are employed in generating input sequences as to which the disambiguation function will be executed. An input sequence is build up in each "session" with each actuation of a key 28 having a number of characters 48 thereon. Since an input sequence typically will be made up of at least one actuation of a key 28 having a plurality of characters 48 thereon, the input sequence will be ambiguous. When a word, for example, is completed the current session is ended and a new session is initiated.

An input sequence is gradually built up on the handheld electronic device 4 with each successive actuation of a key 28 during any given session. Specifically, once a delimiter input is detected during any given session, the session is terminated and a new session is initiated. Each input resulting from an actuation of one of the keys 28 having a number of the characters 48 associated therewith is sequentially added to the current input sequence. As the input sequence grows during a given session, the disambiguation function generally is executed with each actuation of a key 28, i.e., and input, and as to the entire input sequence. Stated otherwise, within a given session, the growing input sequence is attempted to be disambiguated as a unit by the disambiguation function with each successive actuation of the various keys 28.

Once a current input representing a most recent actuation of the one of the keys 28 having a number of the characters 48 assigned thereto has been added to the current input sequence within the current session, as at 216 in Fig. 3A, the disambiguation function generates, as at 220, substantially all of the permutations of the characters 48 assigned to the
various keys 28 that were actuated in generating the input sequence. In this regard, the "permutations" refer to the various strings that can result from the characters 48 of each actuated key 28 limited by the order in which the keys 28 were actuated. The various permutations of the characters in the input sequence are employed as prefix objects.

For instance, if the current input sequence within the current session is the ambiguous input of the keys <AS> and <OP>, the various permutations of the first character 52 and the second character 56 of each of the two keys 28, when considered in the sequence in which the keys 28 were actuated, would be "SO", "SP", "AP", and "AO", and each of these is a prefix object that is generated, as at 220, with respect to the current input sequence. As will be explained in greater detail below, the disambiguation function seeks to identify for each prefix object one of the word objects 108 for which the prefix object would be a prefix.

For each generated prefix object, the memory 20 is consulted, as at 224, to identify, if possible, for each prefix object one of the word objects 108 in the memory 20 that corresponds with the prefix object, meaning that the sequence of letters represented by the prefix object would be either a prefix of the identified word object 108 or would be substantially identical to the entirety of the word object 108. Further in this regard, the word object 108 that is sought to be identified is the highest frequency word object 108. That is, the disambiguation function seeks to identify the word object 108 that corresponds with the prefix object and that also is associated with a frequency object 104 having a relatively higher frequency value than any of the other frequency objects 104 associated with the other word objects 108 that correspond with the prefix object.

It is noted in this regard that the word objects 108 in the generic word list 88 are generally organized in data tables that correspond with the first two letters of various words. For instance, the data table associated with the prefix "CO" would include all of the words such as "CODE", "COIN", "COMMUNICATION", and the like. Depending upon the quantity of word objects 108 within any given data table, the data table may additionally include sub-data tables within which word objects 108 are organized by prefixes that are three characters or more in length. Continuing onward with the foregoing example, if the "CO" data table included, for instance, more than 256 word objects 108, the "CO" data table would additionally include one or more sub-data tables of word objects 108 corresponding with the
most frequently appearing three-letter prefixes. By way of example, therefore, the "CO" data
table may also include a "COM" sub-data table and a "CON" sub-data table. If a sub-data
table includes more than the predetermined number of word objects 108, for example a
quantity of 256, the sub-data table may include further sub-data tables, such as might be
organized according to a four letter prefixes. It is noted that the aforementioned quantity of
256 of the word objects 108 corresponds with the greatest numerical value that can be stored
within one byte of the memory 20.

Accordingly, when, at 224, each prefix object is sought to be used to identify a
corresponding word object 108, and for instance the instant prefix object is "AP", the "AP"
data table will be consulted. Since all of the word objects 108 in the "AP" data table will
correspond with the prefix object "AP", the word object 108 in the "AP" data table with
which is associated a frequency object 104 having a frequency value relatively higher than
any of the other frequency objects 104 in the "AP" data table is identified. The identified
word object 108 and the associated frequency object 104 are then stored in a result register
that serves as a result of the various comparisons of the generated prefix objects with the
contents of the memory 20.

It is noted that one or more, or possibly all, of the prefix objects will be prefix objects
for which a corresponding word object 108 is not identified in the memory 20. Such prefix
objects are considered to be orphan prefix objects and are separately stored or are otherwise
retained for possible future use. In this regard, it is noted that many or all of the prefix objects
can become orphan object if, for instance, the user is trying to enter a new word or, for
example, if the user has mis-keyed and no word corresponds with the mis-keyed input.

Once the result has been obtained at 224, the disambiguation function determines, as
at 228, whether artificial variants should be generated. In order to determine the need for
artificial variants, the process at 228 branches, as at 230, to the artificial variant process
depicted generally in Fig. 4 and beginning with the numeral 304. The disambiguation
function then determines, as at 308, whether any of the prefix objects in the result correspond
with what had been the default output 76 prior to detection of the current key input. If a
prefix object in the result corresponds with the previous default output, this means that the
current input sequence corresponds with a word object 108 and, necessarily, the previous
default output also corresponded with a word object 108 during the previous disambiguation cycle within the current session.

The next point of analysis is to determine, as at 310, whether the previous default output was made the default output because of a selection input, such as would have caused the setting of a flag, such as at 254 of Fig. 3B, discussed in greater detail below. In the event that the previous default output was not the result of a selection input, no artificial variants are needed, and the process returns, as at 312, to the main process at 232. However, if it is determined at 310 that the previous default output was the result of a selection input, then artificial variants are generated, as at 316.

More specifically, each of the artificial variants generated at 316 include the previous default output plus one of the characters 48 assigned to the key 28 of the current input. As such, if the key 28 of the current input has two characters, i.e., a first character 52 and a second character 56, two artificial variants will be generated at 316. One of the artificial variants will include the previous default output plus the first character 52. The other artificial variant will include the previous default output plus the second character 56.

However, if it is determined at 308 that none of the prefix objects in the result correspond with the previous default output, it is next necessary to determine, as at 314, whether the previous default output had corresponded with a word object 108 during the previous disambiguation cycle within the current session. If the answer to the inquiry at 314 is no, it is still necessary to determine, as at 318, whether the previous default output was made the default output because of a selection input, such as would have caused the setting of the flag. In the event that the previous default output was not the result of a selection input, no artificial variants are needed, and the process returns, as at 312, to the main process at 232. However, if it is determined at 318 that the previous default output was the result of a selection input, then artificial variants are generated, as at 316.

On the other hand, if it is determined that the answer to the inquiry at 314 is yes, meaning that the previous default output had corresponded with a word object, but with the current input the previous default output combined with the current input has ceased to correspond with any word object 108, then artificial variants are generated, again as at 316.
After the artificial variants are generated at 316, the method then determines, as at 320, whether the result includes any prefix objects at all. If not, processing returns, as at 312, to the main process at 232. However, if it is determined at 320 that the result includes at least a first prefix object, meaning that the current input sequence corresponds with a word object 108, processing is transferred to 324 where an additional artificial variant is created. Specifically, the prefix object of the result with which is associated the frequency object 104 having the relatively highest frequency value among the other frequency objects 104 in the result is identified, and the artificial variant is created by deleting the final character from the identified prefix object and replacing it with an opposite character 48 on the same key 28 of the current input that generated the final character 48 of the identified prefix object. In the event that the specific key 28 has more than two characters 48 assigned thereto, each such opposite character 48 will be used to generate an additional artificial variant.

Once the need for artificial variants has been identified, as at 228, and any such artificial variants have been generated, as in Fig. 4 and as described above, processing continues, as at 232, where the need for non-alphabetic objects is determined. As can be understood from the foregoing, the prefix objects that are generated, as at 220, each comprise a number of the alphabetic characters 48 assigned to the keys 28. However, a determination is initiated, as at 232, whether one or more non-alphabetic characters that may be assigned to keys 28 in the input sequence should be provided as at least a portion of an output.

Specifically, upon initiating a determination as to the need for non-alphabetic objects, as at 232, processing continues at 233 where processing is transferred to Fig. 4A for a subsystem. More particularly, processing is transferred to the element 234 in Fig. 4A, after which it is determined, as at 235, whether each key 28 of the input sequence has a numeric character 53 assigned thereto. If it is determined, as at 235, that fewer than all of the keys 28 of the input sequence have assigned thereto a numeric character 53, processing continues, as at 237, where it is determined whether or not the key 28 of the current input member actuation has a symbol character 55 assigned thereto. If at 237 it is determined that the current input member actuation has no symbol character 55 assigned thereto, no need exists for a non-alphabetic object to be generated, and processing thereafter returns, as at 239, to the main process at 235 in Fig. 3A.
However, if it is determined at 235 that each key 28 of the input sequence has at least one numeric character 53 assigned thereto, processing continues, as at 241, where a numeric interpretation of the input sequence is generated for subsequent output, as will be described in greater detail below. Processing thereafter continues, as at 243, where it is determined whether or not a word object 108 matches one of the generated prefix objects and has associated therewith a frequency object 104 having a frequency value above a predetermined threshold. As employed herein, the expression "match" and variations thereof in the context of language objects 100 and prefix objects shall refer broadly to a situation wherein the quantity of characters in a language object 100 is equal to the quantity of characters in a given prefix object, with the characters of the language object being one-for-one the same as those of the given prefix object. If no such matching word object 108 is identified at 243, processing returns to the main process, as at 235. However, if at 243 a matching word object 108 having a sufficiently high frequency value is identified, processing continues, as at 245, where a flag is set for future use, as will be described in greater detail below. After the flag is set, as at 245, processing returns to the main process, as at 235.

Still alternatively, if it is determined, as at 237, that the key 28 of the current input member actuation has a symbol character 55 assigned thereto, processing continues, as at 247, where it is determined whether the current input member actuation was a particular type of actuation, such as a press-and-hold actuation of a predetermined duration or longer. If the answer at 247 is yes, meaning that the current input member actuation was of a predetermined type, such as the aforementioned press-and-hold actuation of a predetermined duration, processing continues, as at 249, where a flag is set for use as will be described in greater detail below. Afterward, processing continues, as at 251, where a proposed interpretation of the input sequence is generated. The proposed interpretation comprises a disambiguated text interpretation of an initial portion of the input sequence followed by a symbol character 55 that is assigned to the key 28 of the current input member actuation. The disambiguated text interpretation typically would comprise a word object 108, although this need not necessary be the case. Processing thereafter returns to the main process, as at 235.

On the other hand, if it is determined, as at 247, that the current input member actuation was not a particular type of actuation, such as not being the exemplary press-and-
hold actuation of a predetermined duration, processing would continue, as at 253, where it is determined whether any language objects 100 correspond with the input sequence. If one or more such language objects 100 are identified at 253, processing returns to the main process, as at 235. However, if it is determined at 253 that no language objects 100 correspond with the input sequence, processing continues to 251 where the proposed interpretation of the input sequence is generated as was mentioned above. Processing thereafter returns to the main process, as at 235.

Once processing has returned to 235, duplicate word objects 108 associated with relatively lower frequency values are deleted from the result. Such a duplicate word object 108 could be generated, for instance, by the frequency learning database 96, as will be set forth in greater detail below. If a word object 108 in the result matches one of the artificial variants, the word object 108 and its associated frequency object 104 generally will be removed from the result because the artificial variant will be assigned a preferred status in the output 64, likely in a position preferred to any word object 108 that might have been identified.

Once the duplicate word objects 108 and the associated frequency objects 104 have been removed at 232, the remaining prefix objects are arranged, as at 236, in an output set in decreasing order of frequency value. The orphan prefix objects mentioned above may also be added to the output set, albeit at positions of relatively lower frequency value than any prefix object for which a corresponding word object 108 was found. It is also necessary to ensure that the artificial variants, if they have been created, are placed at a preferred position in the output set. It is understood that artificial variants may, but need not necessarily be, given a position of preference, i.e., assigned a relatively higher priority or frequency, than prefix objects of the result.

If it is determined, as at 240, that the flag has been set, the output set is modified from its typical ordering according to decreasing frequency value. As mentioned above, the flag can be set if, for instance, the user has made a selection input, either through an express selection input or through an alternation input of a movement input. In such a situation, the default output 76 is considered to be "locked," meaning that the selected variant will be the default prefix until the end of the session. As further mentioned above, the flag can
alternatively be set at 245 or 249 of Fig. 4A during the making of the determination whether
or not non-alphabetic objects should be generated.

If it is determined at 240 that the flag has been set, the processing will proceed to 244
where the contents of the output set will be altered, if needed, to provide as the default output
76 an output that includes either the selected prefix object, whether it corresponds with a word
object 108 or is an artificial variant, or the non-alphabetic object generated at 241 or 251 in
Fig. 4A. In the former situation, it is understood that the flag can be set additional times
during a session, in which case the selected prefix object associated with resetting of the flag
thereafter becomes the "locked" default output 76 until the end of the session or until another
selection input is detected.

In the latter situation, the setting of the flag at 245 or 249 provides an indication as to
where in the output 64 the proposed interpretation of the input sequence should be positioned.
As a general matter, and in the situation where it is determined at 235 that each key 28 in the
input sequence has a numeric character 53 assigned thereto, the numeric interpretation of the
input sequence will be progressively output at positions of relatively higher priority, i.e.,
frequency, as the quantity of input members in the input sequence increases. For instance, if
the input sequence is one or two input member actuations in length, any numeric
interpretation of the input sequence likely will be output at a position of very low priority, if
at all. As the quantity of input member actuations in the input sequence reaches three, the
numeric interpretation is output at a position of moderate priority in the variant component 72.

When the input sequence is four actuations or more in length, for instance, the numeric
interpretation typically will be output as the default output 76. However, if it is determined,
as at 243, that a word object 108 matches one of the prefix objects and has a frequency value
at or above a predetermined threshold, the resultant setting of the flag at 245 indicates to the
disambiguation routine 22 that the identified word object 108 should be output as the default
output 76, with the numeric interpretation being output closely thereafter as a variant.

In a similar fashion, if it is determined at 253 that no language objects 100 correspond
with the input sequence, the proposed interpretation of the input sequence is generated at 251
and will typically be output at a position in the variant component 72 of at least moderate
priority. However, if it is determined at 247 that the current input member actuation was a
particular type of actuation, such as the aforementioned press-and-hold actuation of a 
predetermined duration, the flag is set, as at 249, which results in the proposed 
interpretation of the input sequence being generated at 251 and being output as the default output 76. 
Although not expressly depicted in Fig. 4A, it is understood that even if one or more language 
objects are identified at 253 as corresponding with the input sequence, the variant component 
72 still can potentially include a proposed interpretation comprising a disambiguated text 
interpretation of an initial portion of the input sequence followed by a symbol character 55 
assigned to the key of the current input, as is generated at 251. However, in this type of 
situation such a proposed interpretation typically would be output at a position in the variant 
component 72 of relatively low priority, if it is output at all.

Processing then continues, as at 248, to an output step after which an output 64 is 
generated as described above. More specifically, processing proceeds, as at 250, to the 
subsystem depicted generally in Fig. 6 and described below. Processing thereafter continues 
at 204 where additional input is detected. On the other hand, if it is determined at 240 that the 
flag had not been set, then processing goes directly to 248 without the alteration of the 
contents of the output set at 244.

The handheld electronic device 4 may be configured such that any orphan prefix 
object that is included in an output 64 but that is not selected with the next input is suspended. 
This may be limited to orphan prefix objects appearing in the variant portion 80 or may apply 
to orphan prefix objects anywhere in the output 64. The handheld electronic device 4 may 
also be configured to similarly suspend artificial variants in similar circumstances. A reason 
for such suspension is that each such orphan prefix object and/or artificial variant, as 
appropriate, may spawn a quantity of offspring orphan prefix objects equal to the quantity of 
characters 48 on a key 28 of the next input. That is, each offspring will include the parent 
orphan prefix object or artificial variant plus one of the characters 48 of the key 28 of the next 
input. Since orphan prefix objects and artificial variants substantially do not have 
correspondence with a word object 108, spawned offspring objects from parent orphan prefix 
objects and artificial variants likewise will not have correspondence with a word object 108. 
Such suspended orphan prefix objects and/or artificial variants may be considered to be 
suspended, as compared with being wholly eliminated, since such suspended orphan prefix
objects and/or artificial variants may reappear later as parents of a spawned orphan prefix objects and/or artificial variants, as will be explained below.

If the detected input is determined, as at 212, to be an operational input, processing then continues to determine the specific nature of the operational input. For instance, if it is determined, as at 252, that the current input is a selection input, processing continues at 254. At 254, the word object 108 and the associated frequency object 104 of the default portion 76 of the output 64, as well as the word object 108 and the associated frequency object 104 of the portion of the variant output 80 that was selected by the selection input, are stored in a temporary learning data register. Additionally, the flag is set. Processing then returns to detection of additional inputs as at 204.

If it is determined, as at 260, that the input is a delimiter input, processing continues at 264 where the current session is terminated and processing is transferred, as at 266, to the learning function subsystem, as at 404 of Fig. 5A. Such a delimiter input would be input by the user upon a completion of an intended word, i.e., the delimited input would indicate to the handheld electronic device 4 that the inputting of the particular desired word of the current session has been completed. A delimiter input would include, for example, the actuation of a <SPACE> key 116, which would both enter a delimiter symbol and would add a space at the end of the word, actuation of the <ENTER> key 44, which might similarly enter a delimiter input and enter a space, and by a translation of the thumbwheel 32, such as is indicated by the arrow 38, which might enter a delimiter input without additionally entering a space.

It is first determined, as at 408, whether the default output at the time of the detection of the delimiter input at 260 matches a word object 108 in the memory 20. If it does not, this means that the default output is a user-created output that should be added to the new words database 92 for future use. In such a circumstance processing then proceeds to 412 where the default output is stored in the new words database 92 as a new word object 108. Additionally, a frequency object 104 is stored in the new words database 92 and is associated with the aforementioned new word object 108. The new frequency object 104 is given a relatively high frequency value, typically within the upper one-fourth or one-third of a predetermined range of possible frequency values.
In this regard, frequency objects 104 are given an absolute frequency value generally in the range of zero to 65,535. The maximum value represents the largest number that can be stored within two bytes of the memory 20. The new frequency object 104 that is stored in the new words database 92 is assigned an absolute frequency value within the upper one-fourth or one-third of this range, particularly since the new word was used by a user and is likely to be used again.

With further regard to frequency object 104, it is noted that within a given data table, such as the "CO" data table mentioned above, the absolute frequency value is stored only for the frequency object 104 having the highest frequency value within the data table. All of the other frequency objects 104 in the same data table have frequency values stored as percentage values normalized to the aforementioned maximum absolute frequency value. That is, after identification of the frequency object 104 having the highest frequency value within a given data table, all of the other frequency objects 104 in the same data table are assigned a percentage of the absolute maximum value, which represents the ratio of the relatively smaller absolute frequency value of a particular frequency object 104 to the absolute frequency value of the aforementioned highest value frequency object 104. Advantageously, such percentage values can be stored within a single byte of memory, thus saving storage space within the handheld electronic device 4.

Upon creation of the new word object 108 and the new frequency object 104, and storage thereof within the new words database 92, processing is transferred to 420 where the learning process is terminated. Processing is then returned to the main process, as at 204.

If at 408 it is determined that the word object 108 in the default output 76 matches a word object 108 within the memory 20, processing then continues at 416 where it is determined whether the aforementioned flag has been set, such as occurs upon the detection of a selection input, and alternation input, or a movement input, by way of example. If it turns out that the flag has not been set, this means that the user has not expressed a preference for a variant prefix object over a default prefix object, and no need for frequency learning has arisen. In such a circumstance, processing continues at 420 where the learning process is terminated. Processing then returns to the main process at 204.
However, if it is determined at 416 that the flag has been set, the processor 16 retrieves from the temporary learning data register the most recently saved default and variant word objects 108, along with their associated frequency objects 104. It is then determined, as at 428, whether the default and variant word objects 108 had previously been subject of a frequency learning operation. This might be determined, for instance, by determining whether the variant word object 108 and the associated frequency object 104 were obtained from the frequency learning database 96. If the default and variant word objects 108 had not previously been the subject of a frequency learning operation, processing continues, as at 432, where the variant word object 108 is stored in the frequency learning database 96, and a revised frequency object 104 is generated having a frequency value greater than that of the frequency object 104 that previously had been associated with the variant word object 108. In the present exemplary circumstance, \textit{i.e.}, where the default word object 108 and the variant word object 108 are experiencing their first frequency learning operation, the revised frequency object 104 may, for instance, be given a frequency value equal to the sum of the frequency value of the frequency object 104 previously associated with the variant word object 108 plus one-half the difference between the frequency value of the frequency object 104 associated with the default word object 108 and the frequency value of the frequency object 104 previously associated with the variant word object 108. Upon storing the variant word object 108 and the revised frequency object 104 in the frequency learning database 96, processing continues at 420 where the learning process is terminated and processing returns to the main process, as at 204.

If it is determined at 428 that that default word object 108 and the variant word object 108 had previously been the subject of a frequency learning operation, processing continues to 436 where the revised frequency value 104 is instead given a frequency value higher than the frequency value of the frequency object 104 associated with the default word object 108. After storage of the variant word object 108 and the revised frequency object 104 in the frequency learning database 96, processing continues to 420 where the learning process is terminated, and processing then returns to the main process, as at 204.

With further regard to the learning function, it is noted that the learning function additionally detects whether both the default word object 108 and the variant word object 104
were obtained from the frequency learning database 96. In this regard, when word objects 108 are identified, as at 224, for correspondence with generated prefix objects, all of the data sources in the memory are polled for such corresponding word objects 108 and corresponding frequency objects 104. Since the frequency learning database 96 stores word objects 108 that also are stored either in the generic word list 88 or the new words database 92, the word object 108 and the associated frequency object 104 that are obtained from the frequency learning database 96 typically are duplicates of word objects 108 that have already been obtained from the generic word list 88 or the new words database 92. However, the associated frequency object 104 obtained from the frequency learning database 96 typically has a frequency value that is of a greater magnitude than that of the associated frequency object 104 that had been obtained from the generic word list 88. This reflects the nature of the frequency learning database 96 as imparting to a frequently used word object 108 a relatively greater frequency value than it otherwise would have in the generic word list 88.

It thus can be seen that the learning function indicated in Figs. 5A and 5B and described above is generally not initiated until a delimiter input is detected, meaning that learning occurs only once for each session. Additionally, if the final default output is not a user-defined new word, the word objects 108 that are the subject of the frequency learning function are the word objects 108 which were associated with the default output 76 and the selected variant output 80 at the time when the selection occurred, rather than necessarily being related to the object that ultimately resulted as the default output at the end of the session. Also, if numerous learnable events occurred during a single session, the frequency learning function operates only on the word objects 108 that were associated with the final learnable event, i.e., a selection event, an alternation event, or a movement event, prior to termination of the current session.

With further regard to the identification of various word objects 108 for correspondence with generated prefix objects, it is noted that the memory 20 can include a number of additional data sources 99 in addition to the generic word list 88, the new words database 92, and the frequency learning database 96, all of which can be considered linguistic sources. An exemplary two other data sources 99 are depicted in Fig. 2A, it being understood that the memory 20 might include any number of other data sources 99. The other data
sources 99 might include, for example, an address database, a speed-text database, or any other data source without limitation. An exemplary speed-text database might include, for example, sets of words or expressions or other data that are each associated with, for example, a character string that may be abbreviated. For example, a speed-text database might associate the string "br" with the set of words "Best Regards", with the intention that a user can type the string "br" and receive the output "Best Regards".

In seeking to identify word objects 108 that correspond with a given prefix object, the handheld electronic device 4 may poll all of the data sources in the memory 20. For instance the handheld electronic device 4 may poll the generic word list 88, the new words database 92, the frequency learning database 96, and the other data sources 99 to identify word objects 108 that correspond with the prefix object. The contents of the other data sources 99 may be treated as word objects 108, and the processor 20 may generate frequency objects 104 that will be associated such word objects 108 and to which may be assigned a frequency value in, for example, the upper one-third or one-fourth of the aforementioned frequency range.

Assuming that the assigned frequency value is sufficiently high, the string "br", for example, would typically be output to the display 60. If a delimiter input is detected with respect to the portion of the output having the association with the word object 108 in the speed-text database, for instance "br", the user would receive the output "Best Regards", it being understood that the user might also have entered a selection input as to the exemplary string "br".

The contents of any of the other data sources 99 may be treated as word objects 108 and may be associated with generated frequency objects 104 having the assigned frequency value in the aforementioned upper portion of the frequency range. After such word objects 108 are identified, the new word learning function can, if appropriate, act upon such word objects 108 in the fashion set forth above.

Again regarding Fig. 3A, when processing proceeds to the filtration step, as at 232, and the duplicate word objects 108 and the associated frequency objects 104 having relatively lower frequency values are filtered, the remaining results may include a variant word object 108 and a default word object 108, both of which were obtained from the frequency learning database 96. In such a situation, it can be envisioned that if a user repetitively and alternately
uses one word then the other word, over time the frequency objects associated with such
words will increase well beyond the aforementioned maximum absolute frequency value for a
frequency object. Accordingly, if it is determined that both the default word object and the variant word object in the learning function were obtained from the frequency
learning database, instead of storing the variant word object in the frequency learning database and associating it with a frequency object having a relatively increased
frequency value, instead the learning function stores the default word object and associates it with a revised frequency object having a frequency value that is relatively
lower than that of the frequency object that is associated with the variant word object. Such a scheme advantageously avoids excessive and unnecessary increases in frequency
value.

If it is determined, such as at 268, that the current input is a movement input, such as
would be employed when a user is seeking to edit an object, either a completed word or a
prefix object within the current session, the caret is moved, as at 272, to the desired
location, and the flag is set, as at 276. Processing then returns to where additional inputs can
be detected, as at 204.

In this regard, it is understood that various types of movement inputs can be detected
from the input device. For instance, a rotation of the thumbwheel, such as indicated by
the arrow of Fig. 1, could provide a movement input, as could the actuation of the
&lt;NEXT&gt; key or other such input, potentially in combination with other devices in the
input apparatus. In the instance where such a movement input is detected, such as in the
circumstance of an editing input, the movement input is additionally detected as a selection
input. Accordingly, and as is the case with a selection input such as is detected at 252, the
selected variant is effectively locked with respect to the default portion of the output.

Any default output during the same session will necessarily include the previously selected
variant.

In the context of editing, however, the particular displayed object that is being edited
is effectively locked except as to the character that is being edited. In this regard, therefore,
the other characters of the object being edited, i.e., the characters that are not being edited, are
maintained and are employed as a context for identifying additional word objects.
like that correspond with the object being edited. Were this not the case, a user seeking to edit a letter in the middle of a word otherwise likely would see as a new output 64 numerous objects that bear little or no resemblance to the characters of the object being edited since, in the absence of maintaining such context, an entirely new set of prefix objects including all of the permutations of the characters of the various keystrokes of the object being edited would have been generated. New word objects 108 would have been identified as corresponding with the new prefix objects, all of which could significantly change the output 64 merely upon the editing of a single character. By maintaining the other characters currently in the object being edited, and employing such other characters as context information, the user can much more easily edit a word that is depicted on the display 60.

In the present exemplary embodiment of the handheld electronic device 4, if it is determined, as at 252, that the input is not a selection input, and it is determined, as at 260, that the input is not a delimiter input, and it is further determined, as at 268, that the input is not a movement input, in the current exemplary embodiment of the handheld electronic device 4 the only remaining operational input generally is a detection of the <DELETE> key 86 of the keys 28 of the keypad 24. Upon detection of the <DELETE> key 86, the final character of the default output is deleted, as at 280. At this point, the processing generally waits until another input is detected, as at 284. It is then determined, as at 288, whether the new input detected at 284 is the same as the most recent input that was related to the final character that had just been deleted at 280. If so, the default output 76 is the same as the previous default output, except that the last character is the opposite character of the key actuation that generated the last character. Processing then continues to 292 where learning data, i.e., the word object 108 and the associate frequency object 104 associated with the previous default output 76, as well as the word object 108 and the associate frequency object 104 associated with the new default output 76, are stored in the temporary learning data register and the flag is set. Such a key sequence, i.e., an input, the <DELETE> key 86, and the same input as before, is an alternation input. Such an alternation input replaces the default final character with an opposite final character of the key 28 which generated the final character 48 of the default output 76. The alternation input is treated as a selection input for
purposes of locking the default output 76 for the current session, and also triggers the flag which will initiate the learning function upon detection of a delimiter input at 260.

If it turns out, however, that the system detects at 288 that the new input detected at 284 is different than the input immediately prior to detection of the <DELETE> key 86, processing continues at 212 where the input is determined to be either an operational input or an input of a key having one or more characters 48, and processing continues thereafter.

It is also noted that when the main process reaches the output stage at 248, an additional process is initiated which determines whether the variant component 72 of the output 64 should be initiated. Processing of the additional function is initiated from 248 at element 504 of Fig. 6. Initially, the method at 508 outputs the text component 68 of the output 64 to the display 60. Further processing determines whether or not the variant component 72 should be displayed.

Specifically, it is determined, as at 512, whether the variant component 72 has already been displayed during the current session. If the variant component 72 has already been displayed, processing continues at 516 where the new variant component 72 resulting from the current disambiguation cycle within the current session is displayed. Processing then returns to a termination point at 520, after which processing returns to the main process at 204. If, however, it is determined at 512 that the variant component 72 has not yet been displayed during the current session, processing continues, as at 524, to determine whether the elapsed time between the current input and the immediately previous input is longer than a predetermined duration. If it is longer, then processing continues at 516 where the variant component 72 is displayed and processing returns, through 520, to the main process, as at 204. However, if it is determined at 524 that the elapsed time between the current input and the immediately previous input is less than the predetermined duration, the variant component 72 is not displayed and processing returns to the termination point at 520, after which processing returns to the main process, as at 204.

Advantageously, therefore, if a user is entering keystrokes relatively quickly, the variant component 72 will not be output to the display 60, where it otherwise would likely create a visual distraction to a user seeking to enter keystrokes quickly. If at any time during a given session the variant component 72 is output to the display 60, such as if the time
between successive inputs exceeds the predetermined duration, the variant component 72 will continue to be displayed throughout that session. However, upon the initiation of a new session, the variant component 72 will be withheld from the display if the user consistently is entering keystrokes relatively quickly.

An exemplary input sequence is depicted in Figs. 1 and 7-11. In this example, the user is attempting to enter the word "APPLOADER", and this word presently is not stored in the memory 20. In Fig. 1 the user has already typed the <AS> key 28. Since the data tables in the memory 20 are organized according to two-letter prefixes, the contents of the output 64 upon the first keystroke are obtained from the N-gram objects 112 within the memory. The first keystroke <AS> corresponds with a first N-gram object 112 "S" and an associated frequency object 104, as well as another N-gram object 112 "A" and an associated frequency object 104. While the frequency object 104 associated with "S" has a frequency value greater than that of the frequency object 104 associated with "A", it is noted that "A" is itself a complete word. A complete word is always provided as the default output 76 in favor of other prefix objects that do not match complete words, regardless of associated frequency value. As such, in Fig. 1, the default portion 76 of the output 64 is "A".

In Fig. 7, the user has additionally entered the <OP> key 28. The variants are depicted in Fig. 7. Since the prefix object "SO is also a word, it is provided as the default output 76. In Fig. 8, the user has again entered the <OP> key 28 and has also entered the <L> key 28. It is noted that the exemplary <L> key 28 depicted herein includes only the single character 48 "L".

It is assumed in the instant example that no operational inputs have thus far been detected. The default output 76 is "APPL", such as would correspond with the word "APPLE". The prefix "APPL" is depicted both in the text component 68, as well as in the default portion 76 of the variant component 72. Variant prefix objects in the variant portion 80 include "APOL", such as would correspond with the word "APOLOGIZE", and the prefix "SPOL", such as would correspond with the word "SPOLIATION".

It is particularly noted that the additional variants "AOOL", "AOPL", "SOPL", and "SOOL" are also depicted as variants 80 in the variant component 72. Since no word object 108 corresponds with these prefix objects, the prefix objects are considered to be orphan
prefix objects for which a corresponding word object 108 was not identified. In this regard, it
may be desirable for the variant component 72 to include a specific quantity of entries, and in
the case of the instant exemplary embodiment the quantity is seven entries. Upon obtaining
the result at 224, if the quantity of prefix objects in the result is fewer than the predetermined
quantity, the disambiguation function will seek to provide additional outputs until the
predetermined number of outputs are provided. In the absence of artificial variants having
been created, the additional variant entries are provided by orphan prefix objects. It is noted,
however, that if artificial variants had been generated, they likely would have occupied a
place of preference in favor of such orphan prefix objects, and possibly also in favor of the
prefix objects of the result.

It is further noted that such orphan prefix objects may actually be offspring orphan
prefix objects from suspended parent orphan prefix objects and/or artificial variants. Such
offspring orphan prefix objects can be again output depending upon frequency ranking as
explained below, or as otherwise ranked.

The orphan prefix objects are ranked in order of descending frequency with the use of
the N-gram objects 112 and the associated frequency objects 104. Since the orphan prefix
objects do not have a corresponding word object 108 with an associated frequency object 104,
the frequency objects 104 associated with the various N-gram objects 112 must be employed
as a fallback.

Using the N-gram objects 112, the disambiguation function first seeks to determine if
any N-gram object 112 having, for instance, three characters is a match for, for instance, a
final three characters of any orphan prefix object. The example of three characters is given
since the exemplary embodiment of the handheld electronic device 4 includes N-gram objects
112 that are an exemplary maximum of the three characters in length, but it is understood that
if the memory 20 included N-gram objects four characters in length or longer, the
disambiguation function typically would first seek to determine whether an N-gram object
having the greatest length in the memory 20 matches the same quantity of characters at the
end of an orphan prefix object.

If only one prefix object corresponds in such a fashion to a three character N-gram
object 112, such orphan prefix object is listed first among the various orphan prefix objects in
the variant output 80. If additional orphan prefix objects are matched to N-gram objects 112 having three characters, then the frequency objects 104 associated with such identified N-gram objects 112 are analyzed, and the matched orphan prefix objects are ranked amongst themselves in order of decreasing frequency.

If it is determined that a match cannot be obtained with an N-gram object 112 having three characters, then two-character N-gram objects 112 are employed. Since the memory 20 includes all permutations of two-character N-gram objects 112, a last two characters of each orphan prefix object can be matched to a corresponding two-character N-gram object 112. After such matches are achieved, the frequency objects 104 associated with such identified N-gram objects 112 are analyzed, and the orphan prefix objects are ranked amongst themselves in descending order of frequency value of the frequency objects 104 that were associated with the identified N-gram objects 112. It is further noted that artificial variants can similarly be rank ordered amongst themselves using the N-gram objects 112 and the associated frequency objects 104.

In Fig. 9 the user has additionally entered the <OP> key 28. In this circumstance, and as can be seen in Fig. 9, the default portion 76 of the output 64 has become the prefix object "APOLO" such as would correspond with the word "APOLOGIZE", whereas immediately prior to the current input the default portion 76 of the output 64 of Fig. 8 was "APPL" such as would correspond with the word "APPLE." Again, assuming that no operational inputs had been detected, the default prefix object in Fig. 9 does not correspond with the previous default prefix object of Fig. 8. As such, the first artificial variant "APOLP" is generated and in the current example is given a preferred position. The aforementioned artificial variant "APOLP" is generated by deleting the final character of the default prefix object "APOL" and by supplying in its place an opposite character 48 of the key 28 which generated the final character of the default portion 76 of the output 64, which in the current example of Fig. 9 is "P", so that the aforementioned artificial variants is "APOLP".

Furthermore, since the previous default output "APPL" corresponded with a word object 108, such as the word object 108 corresponding with the word "APPLE", and since with the addition of the current input the previous default output "APPL" no longer corresponds with a word object 108, two additional artificial variants are generated. One
artificial variant is "APPLP" and the other artificial variant is "APPLO", and these correspond
with the previous default output "APPL" plus the characters 48 of the key 28 that was
actuated to generate the current input. These artificial variants are similarly output as part of
the variant portion 80 of the output 64.

As can be seen in Fig. 9, the default portion 76 of the output 64 "APOLO" no longer
seems to match what would be needed as a prefix for "APPLOADER", and the user likely
anticipates that the desired word "APPLOADER" is not already stored in the memory 20. As
such, the user provides a selection input, such as by scrolling with the thumbwheel 32, or by
actuating the <NEXT> key 40, until the variant string "APPLO" is highlighted. The user then
continues typing and enters the <AS> key.

The output 64 of such action is depicted in Fig. 10. Here, the string "APPOA" is the
default portion 76 of the output 64. Since the variant string "APPO" became the default
portion 76 of the output 64 (not expressly depicted herein) as a result of the selection input as
to the variant string "APPLO", and since the variant string "APPO" does not correspond
with a word object 108, the character strings "APPOA" and "APPOS" were created as an
artificial variants. Additionally, since the previous default of Fig. 9, "APOLO" previously
had corresponded with a word object 108, but now is no longer in correspondence with the
default portion 76 of the output 64 of Fig. 10, the additional artificial variants of "APOLOA"
and "APOLOS" were also generated. Such artificial variants are given a preferred position in
favor of the three displayed orphan prefix objects.

Since the current input sequence in the example no longer corresponds with any word
object 108, the portions of the method related to attempting to find corresponding word
objects 108 are not executed with further inputs for the current session. That is, since no word
object 108 corresponds with the current input sequence, further inputs will likewise not
correspond with any word object 108. Avoiding the search of the memory 20 for such
nonexistent word objects 108 saves time and avoids wasted processing effort.

As the user continues to type, the user ultimately will successfully enter the word
"APPLOADER" and will enter a delimiter input. Upon detection of the delimiter input after
the entry of "APPLOADER", the learning function is initiated. Since the word
"APPLOADER" does not correspond with a word object 108 in the memory 20, a new word
object 108 corresponding with "APPLOADER" is generated and is stored in the new words database 92, along with a corresponding new frequency object 104 which is given an absolute frequency in the upper, say, one-third or one-fourth of the possible frequency range. In this regard, it is noted that the new words database 92 and the frequency learning database 96 are generally organized in two-character prefix data tables similar to those found in the generic word list 88. As such, the new frequency object 104 is initially assigned an absolute frequency value, but upon storage the absolute frequency value, if it is not the maximum value within that data table, will be changed to include a normalized frequency value percentage normalized to whatever is the maximum frequency value within that data table.

As a subsequent example, in Fig. 11 the user is trying to enter the word "APOLOGIZE". The user has entered the key sequence <AS> <OP> <OP> <L> <OP>. Since "APPLOADER" has now been added as a word object 108 to the new words database 92 and has been associated with frequency object 104 having a relatively high frequency value, the prefix object "APPLO" which corresponds with "APPLOADER" has been displayed as the default portion 76 of the output 64 in favor of the variant prefix object "APOLO", which corresponds with the desired word "APOLOGIZE." Since the word "APOLOGIZE" corresponds with a word object 108 that is stored at least in the generic word list 88, the user can simply continue to enter keystrokes corresponding with the additional letters "GIZE", which would be the letters in the word "APOLOGIZE" following the prefix object "APLO", in order to obtain the word "APOLOGIZE". Alternatively, the user may, upon seeing the output 64 depicted in Fig. 11, enter a selection input to affirmatively select the variant prefix object "APLO". In such a circumstance, the learning function will be triggered upon detection of a delimiter symbol, and the word object 108 that had corresponded with the character string "APLO" at the time the selection input was made will be stored in the frequency learning database 96 and will be associated with a revised frequency object 104 having a relatively higher frequency value that is similarly stored in the frequency learning database 96.

An additional feature of the handheld electronic device 4 is depicted generally in Fig. 12. In some circumstances, it is desirable that the disambiguation function be disabled. For instance, when it is desired to enter a password, disambiguation typically is relatively more
cumbersome than during ordinary text entry. As such, when the system focus is on the component corresponding with the password field, the component indicates to the API that special processing is requested, and the API disables the disambiguation function and instead enables, for instance, a multi-tap input interpretation system. Alternatively, other input interpretation systems could include a chording system or a press-and-hold / press-and-release interpretation system. As such, while an input entered with the disambiguation function active is an ambiguous input, by enabling the alternative interpretation system, such as the exemplary multi-tap system, each input can be largely unambiguous.

As can be understood from Fig. 12, each unambiguous input is displayed for a very short period of time within the password field 120, and is then replaced with another output, such as the asterisk. The character "R" is shown displayed, it being understood that such display is only for a very short period of time.

As can be seen in Figs. 1 and 7-11, the output 64 includes the displayed graphic 46 near the lower end of the variant component 72, and that the displayed graphic 46 is highly similar to the graphic 42 of the <NEXT> key 40. Such a depiction provides an indication to the user which of the keys 28 of the keypad 24 can be actuated to select a variant output. The depiction of the displayed graphic 46 provides an association between the output 64 and the <NEXT> key 40 in the user's mind. Additionally, if the user employs the <NEXT> key 40 to provide a selection input, the user will be able to actuate the <NEXT> key 40 without moving the user's hands away from the position the hands were in with respect to the housing 6 during text entry, which reduces unnecessary hand motions, such as would be required if a user needed to move a hand to actuate the thumbwheel 32. This saves time and effort.

It is also noted that the system can detect the existence of certain predefined symbols as being delimiter signals if no word object 108 corresponds with the text entry that includes the symbol. For instance, if the user desired to enter the input 'one-off', the user might begin by entering the key sequence <OP> <BN> <ER> <ZX> <OP>, with the <ZX> actuation being intended to refer to the hyphen symbol disposed thereon. Alternatively, instead of typing the <ZX> key the user might actuate an <ALT> entry to unambiguously indicate the hyphen.
Assuming that the memory 20 does not already include a word object 108 of "one-off", the disambiguation function will detect the hyphen as being a delimiter input. As such, the key entries preceding the delimiter input will be delimited from the key entries subsequent to the delimiter input. As such, the desired input will be searched as two separate words, i.e., "ONE" and "OFF", with the hyphen therebetween. This facilitates processing by more narrowly identifying what is desired to be searched.

Figs. 13-19 depict the outputting of non-alphabetic objects in the variant component 72. Figs. 13-17 depict sequentially the output with each keystroke of the input sequence <DF> <UI> <BN> <DF> <UI> such as if the user was attempting to type the word "finding" or was attempting to enter a number beginning with the digits 43843. In Figs. 13 and 14, which depict the first and second keystrokes, respectively, the non-alphabetic objects 78 "4" and "43" are output at the bottom of the variant component 72, i.e., at a position of relatively low priority. However, beginning with the third keystroke, as in Fig. 15, the non-alphabetic object 78 "438" is output in the variant component 72 at a position of moderate priority. In Fig. 16, with the fourth keystroke, the non-alphabetic object 78 "4384" ordinarily would be output at a position of very high priority, possibly as the default output 76. However, it is noted that the default output 76 "find" and the first variant output "fund" each are word objects 108 that match the input sequence at that point of the fourth keystroke and with which are associated frequency objects 104 having relatively high frequency values. In such a circumstance, the word objects "find" and "fund" 108 would be output at a higher priority than the non-alphabetic object 78 "4384". With Fig. 17, however, which depicts the fifth keystroke in the input sequence, the non-alphabetic object 78 is output at a position of highest priority, i.e., as the default output 76, since no word object 108 matches the input sequence, and at most a number of language objects 100 correspond with the input sequence. For instance, the word objects 108 for the words "finding" and "funding" each have an initial portion that matches the input sequence, but the words "finding" and "funding" do not in their entirety match the input sequence because input sequence is of a different length than either of the words. As such, no alphabetic object is output at a higher priority than the non-alphabetic object 78. This advantageously enables a numeric object, such as the non-alphabetic object 78 "43843", to be generated by the text disambiguation routine 22 without the need for the
user to, for instance, activate a separate numeric input routine or hold a <SHIFT> key or <ALT> key while actuating the keys 28 to which numeric characters 53 are assigned.

Fig. 18 depicts an output that would result from the input sequence <DF> <UI> <BN> <QW>. The first three input member actuations of this input sequence would produce an output similar to that of Fig. 15. As can be seen in Fig. 15, the word "fun" is output as the default output 76. However, and as can be seen in Fig. 18, when the current input member actuation is an actuation of the <QW> key 28, no word object 108 corresponds with the input sequence. However, since the exclamation point symbol (!) is a symbol character 55 that is assigned to the <QW> key 28, the disambiguation routine 22 can interpret the input sequence as the word "fun" followed by the exclamation point (!). That is, the user was able to access the exclamation point symbol character 55 using the text disambiguation routine 22 and employing a determination by the text disambiguation routine 22 that the non-alphabetic object "fun!" would be preferable to any possible alphabetic object. In this regard, it is understood that the expression "non-alphabetic object" and variations thereof refer generally to an object having at least one non-alphabetic character and does not require all of the characters therein to be non-alphabetic.

Fig. 19 depicts a situation similar to Fig. 18, except in Fig. 18 the current input member actuation was press-and-hold actuation of a predetermined duration of the <AS> key 28. The word objects 108 "fins" and "dubs" match the input sequence in Fig. 19. However, since the current input member was a press-and-hold actuation of a predetermined duration, and because the question mark (?) symbol character 55 is assigned to the <AS> key 28, the press-and-hold actuation of the current input member enabled the user to unambiguously express a preference for the question mark (?) symbol character 55 assigned thereto without the need to execute another input routine or to additionally actuate a <SHIFT> key or an <ALT> key. In the absence of the current input member actuation being a press-and-hold actuation of a predetermined duration, the word "fins" would have been output as the default output 76, as can be understood from the element 253 in Fig. 4A. However, since the user unambiguously expressed a preference for the question mark (?), and because the initial keystrokes of the input sequence matched the word object 108 "fun", the non-alphabetic
object "fun?" 182 was output as the default output 76. Again, the user was able to access a symbol character 55 directly with the use of the text disambiguation routine 22.

It is noted that the exemplary keypad 24 depicted in Fig. 1 is not intended to be limiting upon the disclosed and claimed concept. For instance, many of the methods described herein can be advantageously implemented on keypads with different arrangements of alphabetic and non-alphabetic characters. For instance, an alternate keypad might have at most only a single alphabetic character assigned to each key in addition to one or more non-alphabetic characters of functions that might be assigned to each such key. Such a keypad would not likely be considered to be a "reduced" keyboard since an input member actuation would not result in an ambiguous text input. However, the input from such an input member actuation could still have an ambiguity as between a sole alphabetic character assigned thereto and one or more non-alphabetic characters assigned thereto. As such, the disambiguation routine executed thereon might not be, per se, a text disambiguation routine, but rather might be a disambiguation routine which resolves other types of input ambiguities.

By way of example, a handheld electronic device having such an alternate keypad might employ a disambiguation routine which outputs a textual interpretation of an input with most input member actuations, but that begins to additionally or alternatively provide a numeric interpretation of the input when a predetermined number of keys having a numeric character assigned thereto are actuated in a series. This would be essentially the same implementation as described above on the handheld electronic device 4, except that the textual portion of the output would not be ambiguous, and rather any variants that might be provided would be numeric or would be textual with one or more symbolic characters in place of alphabetic characters. Any such outputs would still be considered to be disambiguated outputs, whether disambiguated outputs that are text outputs, numeric outputs, or partial text outputs, since the inputs were ambiguous. Similarly, as with the press-and-hold actuation of a key having a symbol character assigned thereto, such an alternate type of input member actuation could unambiguously indicate to the disambiguation routine that the symbol character is desired rather than the alphabetic character. In such a circumstance the device might simply output as an interpretation of the input a textual interpretation plus the desired
symbol character without outputting any variants that would be purely alphabetic or purely numeric.

An improved handheld electronic device 1004 in accordance with another embodiment of the disclosed and claimed concept is depicted generally in Fig. 20. As a general matter, the handheld electronic device 1004 is substantially identical in configuration and function to the handheld electronic device 4, except that the handheld electronic device 1004 employs a multiple-axis input device instead of or in addition to the thumbwheel 32. In the depicted exemplary embodiment, the multiple-axis input device is a track ball 1032 as will be described below. It is noted, however, that multiple-axis input devices other than the track ball 1032 can be employed without departing from the present concept. For instance, other appropriate multiple-axis input devices could include mechanical devices such as joysticks and the like and/or non-mechanical devices such as touch pads, track pads and the like and/or other devices which detect motion or input in other fashions, such as through the use of optical sensors or piezoelectric crystals.

The handheld electronic device 1004 includes a housing 1006 upon which is disposed a processor unit that includes an input apparatus 1008, an output apparatus 1012, a processor 1016, a memory 1020, and a number of routines 1022. All of the operations that can be performed on or with the handheld electronic device 4 can be performed on or with the handheld electronic device 1004. As such, the features of the handheld electronic device 4 that are common with the handheld electronic device 1004, and this would comprise essentially all of the features of the handheld electronic device 4, will generally not be repeated.

The output apparatus 1012 includes a display 1060 that provides visual output. The exemplary output in Fig. 20 is a plurality of icons 1062 that are selectable by the user for the purpose of, for example, initiating the execution on the processor 1016 of a routine 1022 that is represented by an icon 1062.

The input apparatus 1008 can be said to comprise a keypad 1024 and the track ball 1032, all of which serve as input members. The keypad 1024 and the track ball 1032 are advantageously disposed adjacent one another. The keypad 1024 comprises a plurality of keys 1028 that are actuable to provide input to the processor 1016. Many of the keys 1028
have assigned thereto a plurality of linguistic elements in the exemplary form of Latin letters. Other keys 1028 can have assigned thereto functions and/or other characters.

For instance, one of the keys 1028 is an <ESCAPE> key 1031 which, when actuated, provides to the processor 1016 an input that undoes the action which resulted from the immediately preceding input and/or moves the user to a logically higher position within the logical menu tree managed by a graphical user interface (GUI) routine 1022. The function provided by the <ESCAPE> key 1031 can be used at any logical location within any portion of the logical menu tree except, perhaps, at a home screen such as is depicted in Fig. 20. The <ESCAPE> key 1031 is advantageously disposed adjacent the track ball 1032 thereby enabling, for example, an unintended or incorrect input from the track ball 1032 to be quickly undone, i.e., reversed, by an actuation of the adjacent <ESCAPE> key 1031.

Another of the keys 1028 is a <MENU> key 1033 which, when actuated, provides to the processor 1016 an input that causes the GUI 1022 to generate and output on the display 1060 a menu that is appropriate to the user's current logical location within the logical menu tree. For instance, Fig. 21 depicts an exemplary menu 1035A that would be appropriate if the user's current logical location within the logical menu tree was viewing an email within an email routine 1022. That is, the menu 1035A provides selectable options that would be appropriate for a user given that the user is, for example, viewing an email within an email routine 1022. In a similar fashion, Fig. 22 depicts another exemplary menu 1035B that would be depicted if the user's current logical location within the logical menu tree was within a telephone routine 1022.

The track ball 1032 is disposed on the housing 1006 and is freely rotatable in all directions with respect to the housing 1006. A rotation of the track ball 1032 a predetermined rotational distance with respect to the housing 1006 provides an input to the processor 1016, and such inputs can be employed by the routines 1022, for example, as navigational inputs, scrolling inputs, selection inputs, and other inputs.

For instance, the track ball 1032 is rotatable about a horizontal axis 1034A to provide vertical scrolling, navigational, selection, or other inputs. Similarly, the track ball 1032 is rotatable about a vertical axis 1034B to provide horizontal scrolling, navigational, selection, or other inputs. Since the track ball 1032 is freely rotatable with respect to the housing 1006,
the track ball 1032 is additionally rotatable about any other axis (not expressly depicted herein) that lies within the plane of the page of Fig. 20 or that extends out of the plane of the page of Fig. 20.

The track ball 1032 can be said to be a multiple-axis input device because it provides scrolling, navigational, selection, and other inputs in a plurality of directions or with respect to a plurality of axes, such as providing inputs in both the vertical and the horizontal directions. It is reiterated that the track ball 1032 is merely one of many multiple-axis input devices that could be employed on the handheld electronic device 1004. As such, mechanical alternatives to the track ball 1032, such as a joystick, might have a limited rotation with respect to the housing 1006, and non-mechanical alternatives might be immovable with respect to the housing 1006, yet all are capable of providing input in a plurality of directions or along a plurality of axes.

The track ball 1032 additionally is translatable toward the housing 1006, i.e., into the plane of the page of Fig. 20, to provide additional inputs. The track ball 1032 could be translated in such a fashion by, for example, a user applying an actuating force to the track ball 1032 in a direction toward the housing 1006, such as by pressing on the track ball 1032. The inputs that are provided to the processor 1016 as a result of a translation of the track ball 1032 in the indicated fashion can be employed by the routines 1022, for example, as selection inputs, delimiter inputs, or other inputs.

The track ball 1032 is rotatable to provide, for example, navigational inputs among the icons 1062. For example, Fig. 20 depicts the travel of an indicator 1066 from the icon 1062A, as is indicated in broken lines with the indicator 1066A, to the icon 1062B, as is indicated in broken lines with the indicator 1066B, and onward to the icon 1062C, as is indicated by the indicator 1066C. It is understood that the indicators 1066A, 1066B, and 1066C are not necessarily intended to be simultaneously depicted on the display 1060, but rather are intended to together depict a series of situations and to indicate movement of the indicator 1066 among the icons 1062. The particular location of the indicator 1066 at any given time indicates to a user the particular icon 1062, for example, that is the subject of a selection focus of the handheld electronic device 1004. Whenever an icon 1062 or other selectable object is the subject of the selection focus, a selection input to the processor 1016 will result in the
routine 1022 or other function represented by the icon 1062 or other selectable object to be executed or initiated.

The movement of the indicator 1066 from the icon 1062A, as indicated with the indicator 1066A, to the icon 1062B, as is indicated by the indicator 1066B, was accomplished by rotating the track ball 1032 about the vertical axis 1034B to provide a horizontal navigational input. As mentioned above, a rotation of the track ball 1032 a predetermined rotational distance results in an input to the processor 1016. In the present example, the track ball 1032 would have been rotated about the vertical axis 1034B a rotational distance equal to three times the predetermined rotational distance since the icon 1062B is disposed three icons 1062 to the right the icon 1062A. Such rotation of the track ball 1032 likely would have been made in a single motion by the user, but this need not necessarily be the case.

Similarly, the movement of the indicator 1066 from the icon 1062B, as indicated by the indicator 1066B, to the icon 1062C, as is indicated by the indicator 1066C, was accomplished by the user rotating the track ball 1032 about the horizontal axis 1034A to provide a vertical navigational input, so doing, the track ball 1032 would have been rotated a rotational distance equal to two times the predetermined rotational distance since the icon 1062C is disposed two icons 1062 below the icon 1062B. Such rotation of the track ball 1032 likely would have been made in a single motion by the user, but this need not necessarily be the case.

It thus can be seen that the track ball 1032 is rotatable in various directions to provide various navigational and other inputs to the processor 1016. Rotational inputs by the track ball 1032 typically are interpreted by whichever routine 1022 is active on the handheld electronic device 1004 as inputs that can be employed by such routine 1022. For example, the GUI 1022 that is active on the handheld electronic device 1004 in Fig. 20 requires vertical and horizontal navigational inputs to move the indicator 1066, and thus the selection focus, among the icons 1062. If a user rotated the track ball 1032 about an axis oblique to the horizontal axis 1034A and the vertical axis 1034B, the GUI 1022 likely would resolve such an oblique rotation of the track ball 1032 into vertical and horizontal components which could then be interpreted by the GUI 1022 as vertical and horizontal navigational movements, respectively.

In such a situation, if one of the resolved vertical and horizontal navigational movements is of
a greater magnitude than the other, the resolved navigational movement having the greater magnitude would be employed by the GUI 1022 as a navigational input in that direction to move the indicator 1066 and the selection focus, and the other resolved navigational movement would be ignored by the GUI 1022, for example.

When the indicator 1066 is disposed on the icon 1062C, as is indicated by the indicator 1066C, the selection focus of the handheld electronic device 1004 is on the icon 1062C. As such, a translation of the track ball 1032 toward the housing 1006 as described above would provide an input to the processor 1016 that would be interpreted by the GUI 1022 as a selection input with respect to the icon 1062C. In response to such a selection input, the processor 1016 would, for example, begin to execute a routine 1022 that is represented by the icon 1062C. It thus can be understood that the track ball 1032 is rotatable to provide navigational and other inputs in multiple directions, assuming that the routine 1022 that is currently active on the handheld electronic device 1004 can employ such navigational or other inputs in a plurality of directions, and can also be translated to provide a selection input or other input.

Rotational movement inputs from the track ball 1032 could be employed to navigate among, for example, the menus 1035A and 1035B. For instance, after an actuation of the <MENU> key 1033 and an outputting by the GUI 1022 of a resultant menu, the user could rotate the track ball 1032 to provide scrolling inputs to successively highlight the various selectable options within the menu. Once the desired selectable option is highlighted, i.e., is the subject of the selection focus, the user could translate the track ball 1032 toward the housing 1006 to provide a selection input as to the highlighted selectable option. In this regard, it is noted that the <MENU> key 1033 is advantageously disposed adjacent the track ball 1032. This enables, for instance, the generation of a menu by an actuation the <MENU> key 1033, conveniently followed by a rotation the track ball 1032 to highlight a desired selectable option, for instance, followed by a translation of the track ball 1032 toward the housing 1006 to provide a selection input to initiate the operation represented by the highlighted selectable option.

It is further noted that one of the additional inputs that can be provided by a translation of the track ball 1032 is an input that causes the GUI 1022 to output a reduced menu. For
instance, a translation of the track ball 1032 toward the housing 1066 could result in the
generation and output of a more limited version of a menu than would have been generated if
the <MENU> key 1033 had instead been actuated. Such a reduced menu would therefore be
appropriate to the user's current logical location within the logical menu tree and would
provide those selectable options which the user would have a high likelihood of selecting.

Rotational movements of the track ball 1032 could provide scrolling inputs to scroll among
the selectable options within the reduced menu 1035C, and translation movements of the track
ball 1032 could provide selection inputs to initiate whatever function is represented by the
selectable option within the reduce menu 1032 that is currently highlighted.

By way of example, if instead of actuating the <MENU> key 1033 to generate the
menu 1035A the user translated the track ball 1032, the GUI 1022 would generate and output
on the display the reduced menu 1035C that is depicted generally in Fig. 23. The exemplary
reduced menu 1035C provides as selectable options a number of the selectable options from
the menu 1035A that the user would be most likely to select. As such, a user seeking to
perform a relatively routine function could, instead of actuating the <MENU> key 1033 to
display the full menu 1035A, translate the track ball 1032 to generate and output the reduced
menu 1035C. The user could then conveniently rotate the track ball 1032 to provide scrolling
inputs to highlight a desired selectable option, and could then translate the track ball 1032 to
provide a selection input which would initiate the function represented by the selectable
option in the reduced menu 1035C that is currently highlighted.

In the present exemplary embodiment, many of the menus that could be generated as a
result of an actuation of the <MENU> key 1033 could instead be generated and output in
reduced form as a reduced menu in response to a translation of the track ball 1032 toward the
housing 1006. It is noted, however, that a reduced menu might not be available for each full
menu that could be generated from an actuation of the <MENU> key 1033. Depending upon
the user's specific logical location within the logical menu tree, a translation of the track ball
1032 might be interpreted as a selection input rather than an input seeking a reduced menu.
For instance, a translation of the track ball 1032 on the home screen depicted in Fig. 20 would
result in a selection input as to whichever of the icons 1062 is the subject of the input focus.

If the <MENU> key 1033 was actuated on the home screen, the GUI 1022 would output a
menu appropriate to the home screen, such as a full menu of all of the functions that are available on the handheld electronic device 1004, including those that might not be represented by icons 1062 on the home screen.

Fig. 24 depicts a quantity of text that is output on the display 1060, such as during a text entry operation or during a text editing operation, for example. The indicator 1066 is depicted in Fig. 24 as being initially over the letter "L", as is indicated with the indicator 1066D, and having been moved horizontally to the letter "I", as is indicated by the indicator 1066E, and thereafter vertically moved to the letter "W", as is indicated by the indicator 1066F. In a fashion similar to that in Fig. 20, the cursor 1066 was moved among the letters "L", "I", and "W" through the use of horizontal and vertical navigational inputs resulting from rotations of the track ball 1032. In the example of Fig. 24, however, each rotation of the track ball 1032 the predetermined rotational distance would move the indicator 1066 to the next adjacent letter. As such, in moving the indicator 1066 between the letters "L" and "I," the user would have rotated the track ball 1032 about the vertical axis 1034B a rotational distance equal to nine times the predetermined rotational distance, for example, since "I" is disposed nine letters to the right of "L".

Fig. 25 depicts an output 1064 on the display 1060 during, for example, a text entry operation that employs the disambiguation routine 1022. The output 1064 can be said to comprise a text component 1068 and a variant component 1072. The variant component 1072 comprises a default portion 1076 and a variant portion 1080. Fig. 25 depicts the indicator 1066G on the variant 1080 "HAV", such as would result from a rotation of the track ball 1032 about the horizontal axis 1034A to provide a downward vertical scrolling input. In this regard, it is understood that a rotation of the track ball 1032 a distance equal to the predetermined rotational distance would have moved the indicator 1066 from a position (not expressly depicted herein) disposed on the default portion 1076 to the position disposed on the first variant 1080, as is depicted in Fig. 25. Since such a rotation of the track ball 1032 resulted in the first variant 1080 "HAV" being highlighted with the indicator 1066G, the text component 1068 likewise includes the text "HAV" immediately preceding a cursor 1084A.

Fig. 26 depict an alternative output 1064A having an alternative variant component 1072A having a default portion 1076A and a variant portion 1080A. The variant component
1072A is horizontally arranged, meaning that the default portion 1076A and the variants 1080A are disposed horizontally adjacent one another and can be sequentially selected by the user through the use of horizontal scrolling inputs, such as by the user rotating the track ball 1032 the predetermined rotational distance about the vertical axis 1034B. This is to be contrasted with the variant component 1072 of Fig. 25 wherein the default portion 1076 and the variants 1080 are vertically arranged, and which can be sequentially selected by the user through the user of vertical scrolling inputs with the track ball 1032.

In this regard, it can be understood that the track ball 1032 can provide both the vertical scrolling inputs employed in conjunction with the output 1064 as well as the horizontal scrolling inputs employed in conjunction with the output 1064A. For instance, the disambiguation routine 1022 potentially could allow the user to customize the operation thereof by electing between the vertically arranged variant component 1072 and the horizontally arranged variant component 1072A. The track ball 1032 can provide scrolling inputs in the vertical direction and/or the horizontal direction, as needed, and thus is operable to provide appropriate scrolling inputs regardless of whether the user chooses the variant component 1072 or the variant component 1072A. That is, the track ball 1032 can be rotated about the horizontal axis 1034A to provide the vertical scrolling inputs employed in conjunction with the variant component 1072, and also can be rotated about the vertical axis 1034B to provide the horizontal scrolling inputs that are employed in conjunction with the variant component 1064A. The track ball 1032 thus could provide appropriate navigational, strolling, selection, and other inputs depending upon the needs of the routine 1022 active at any time on the handheld electronic device 1004. The track ball 1032 enables such navigational, strolling, selection, and other inputs to be intuitively generated by the user through rotations of the track ball 1032 in directions appropriate to the active routine 1022, such as might be indicated on the display 1060. Other examples will be apparent.

It can further be seen from Fig. 26 that the variant component 1072A additionally includes a value 1081 that is indicative of the language into which the disambiguation routine 1022 will interpret ambiguous text input; hi the example depicted in Fig. 26, the language is English.
As can be seen in Fig. 27, the value 1081 can be selected by the user to cause the
displaying of a list 1083 of alternative values 1085. The alternative values 1085 are indicative
of selectable alternative languages into which the disambiguation routine 1022 can interpret
ambiguous input. A selection of the value 1081 would have been achieved, for example, by
the user providing horizontal scrolling inputs with the track ball 1032 to cause (not expressly
depicted herein) the indicator 1066 to be disposed over the value 1081, and by thereafter
translating the track ball 1032 toward the housing 1006 to provide a selection input.

The alternative values 1085 in the list 1083 are vertically arranged with respect to one
another and with respect to the value 1081. As such, a vertical scrolling input with the track
ball 1032 can result in a vertical movement of the indicator 1066 to a position on one of the
alternative values 1085 which, in the present example, is the alternative value 1085 "FR",
which is representative of the French language. The alternative value 1085 "FR" could
become selected by the user in any of a variety of fashions, such as by actuating the track ball
1032 again, by continuing to enter text, or in other fashions. It thus can be understood from
Fig. 26 and Fig. 27 that the track ball 1032 can be rotated to provide horizontal scrolling
inputs and, when appropriate, to additionally provide vertical scrolling inputs and, when
appropriate, to additionally provide selection inputs, for example.

Fig. 28 depicts another exemplary output on the display 1060 such as might be
employed by a data entry routine 1022. The exemplary output of Fig. 28 comprises a
plurality of input fields 1087 with corresponding descriptions. A cursor 1084D, when
disposed within one of the input fields 1087, indicates to the user that an input focus of the
handheld electronic device 1004 is on that input field 1087. That is, data such as text,
numbers, symbols, and the like, will be entered into whichever input field 1087 is active, i.e.,
is the subject of the input focus. It is understood that the handheld electronic device 1004
might perform other operations or take other actions depending upon which input field 1087
is the subject of the input focus.

Navigational inputs from the track ball 1032 advantageously enable the cursor 1084D,
and thus the input focus, to be switched, i.e., shifted, among the various input fields 1087.
For example, the input fields 1087 could include the input fields 1087A, 1087B, and 1087C.

Fig. 28 depicts the cursor 1084D as being disposed in the input field 1087C, indicating that
The input field 1087C is the subject of the input focus of the handheld electronic device 1004. It is understood that the cursor 1084D, and thus the input focus, can be shifted from the input field 1087C to the input field 1087A, which is disposed adjacent and vertically above the input field 1087C, by providing a vertical scrolling input in the upward direction with the track ball 1032. That is, the track ball 1032 would be rotated the predetermined rotational distance about the horizontal axis 1034. Similarly, the cursor 1084D, and thus the input focus, can be shifted from the input field 1087A to the input field 1087B, which is disposed adjacent and to the right of the input field 1087A, by providing a horizontal scrolling input to the right with the track ball 1032. That is, such a horizontal scrolling input could be provided by rotating the track ball the predetermined rotational distance about the vertical axis 1034B. It thus can be seen that the track ball 1032 is rotatable in a plurality of directions about a plurality axes to provide navigational, scrolling, and other inputs in a plurality of directions among a plurality of input fields 1087. Other types of inputs and/or inputs in other applications will be apparent.

Since the keypad 1024 and the track ball 1032 are advantageously disposed adjacent one another, the user can operate the track ball 1032 substantially without moving the user's hands away from the keypad 1024 during a text entry operation or other operation. It thus can be seen that the track ball 1032 combines the benefits of both the thumbwheel 32 and the <NEXT> key 40. It is noted, however, that other embodiments of the handheld electronic device 1004 (not expressly depicted herein) could include both the track ball 1032 and a <NEXT> key such as the <NEXT> key 40 without departing from the present concept.

While specific embodiments of the disclosed and claimed concept have been described in detail, it will be appreciated by those skilled in the art that various modifications and alternatives to those details could be developed in light of the overall teachings of the disclosure. Accordingly, the particular arrangements disclosed are meant to be illustrative only and not limiting as to the scope of the disclosed and claimed concept which is to be given the full breadth of the claims appended and any and all equivalents thereof.
CLAIMS:

1. A method of enabling input on a handheld electronic device that comprises an output apparatus, an input apparatus comprising a plurality of input members, and a memory, at least some of the input members each having assigned thereto a number of alphabetic characters, at least some of the input members each having assigned thereto at least a first alphabetic character and at least a first non-alphabetic character, the method comprising:
   responsive to each of an initial number of input member actuations in a series of input member actuations, processing the input member actuation and any preceding input member actuations in the series as an ambiguous input and outputting a disambiguated text interpretation; and
   responsive to at least one of a number of predetermined events, processing at least a current input member actuation in the series as a non-alphabetic input and outputting a non-alphabetic character assigned to the current input member.

2. The method of Claim 1, further comprising:
   making a determination that each input member actuation in the series is an actuation of an input member having as a non-alphabetic character assigned thereto a numeric character assigned thereto;
   employing the making of the determination as one of the number of predetermined events; and
   outputting a numeric interpretation of the series.

3. The method of Claim 2, further comprising outputting in a list the numeric interpretation and a number of disambiguated text interpretations of the series.

4. The method of Claim 3, further comprising outputting the numeric interpretation in the list at a position that is based at least in part upon the quantity of input member actuations in the series.
5. The method of Claim 4, further comprising:
   with each of at least some of the successive input member actuations in the
   series, outputting the numeric interpretation in the list at a position of progressively increasing
   priority.

6. The method of Claim 4, further comprising:
   outputting as the list a default portion and a variant portion;
   outputting the numeric interpretation as the default portion responsive at least
   in part to the quantity of input member actuations in the series reaching a predetermined
   quantity.

7. The method of Claim 6 wherein the memory has stored therein a plurality of
   objects comprising a plurality of language objects and a plurality of frequency objects, at least
   some of the language objects each being associated with a frequency object, and further
   comprising outputting the numeric interpretation as the default portion responsive at least in
   part to an absence of a language object that matches the series.

8. The method of Claim 1 wherein the memory has stored therein a plurality of
   objects comprising a plurality of language objects and a plurality of frequency objects, at least
   some of the language objects each being associated with a frequency object, and further
   comprising:
   making a determination that no language object corresponds with the series;
   employing the making of the determination as one of the number of
   predetermined events; and
   outputting as an interpretation of the series a disambiguated text interpretation
   of the initial input member actuations plus a symbol character assigned to the current input
   member.

9. The method of Claim 1, further comprising:
making a determination that the current input member actuation is a press-and-
hold actuation of a predetermined duration;
employing the making of the determination as one of the number of
predetermined events; and
outputting as a proposed interpretation of the series a disambiguated text
interpretation of the initial input member actuations and a symbol character assigned to the
current input member.

10. The method of Claim 9, further comprising:
outputting in a list the proposed interpretation and a number of disambiguated
text interpretations of the series; and
outputting the proposed interpretation in the list at a position of relatively
higher priority than at least some of the disambiguated text interpretations.

11. A handheld electronic device comprising:
a processor apparatus comprising a processor and a memory;
an input apparatus being structured to provide input to the processor and
comprising a plurality of input members, at least some of the input members each having
assigned thereto a number of alphabetic characters, at least some of the input members each
having assigned thereto at least a first alphabetic character and at least a first non-alphabetic
character;
an output apparatus structured to receive output signals from the processor
apparatus;
the memory further having stored therein a number of routines which, when
executed on the processor, cause the handheld electronic device to perform operations
comprising:
responsive to each of an initial number of input member actuations in a series
of input member actuations, processing the input member actuation and any preceding input
member actuations in the series as an ambiguous input and outputting a disambiguated text
interpretation; and
responsive to at least one of a number of predetermined events, processing at least a current input member actuation in the series as a non-alphabetic input and outputting a non-alphabetic character assigned to the current input member.

12. The handheld electronic device of Claim 11 wherein the operations further comprise:
   making a determination that each input member actuation in the series is an actuation of an input member having as a non-alphabetic character assigned thereto a numeric character assigned thereto;
   employing the making of the determination as one of the number of predetermined events; and
   outputting a numeric interpretation of the series.

13. The handheld electronic device of Claim 12 wherein the operations further comprise outputting in a list the numeric interpretation and a number of disambiguated text interpretations of the series.

14. The handheld electronic device of Claim 13 wherein the operations further comprise outputting the numeric interpretation in the list at a position that is based at least in part upon the quantity of input member actuations in the series.

15. The handheld electronic device of Claim 14 wherein the operations further comprise:
   with each of at least some of the successive input member actuations in the series, outputting the numeric interpretation in the list at a position of progressively increasing priority.

16. The handheld electronic device of Claim 14 wherein the operations further comprise:
   outputting as the list a default portion and a variant portion.
outputting the numeric interpretation as the default portion responsive at least in part to the quantity of input member actuations in the series reaching a predetermined quantity.

17. The handheld electronic device of Claim 16 wherein the memory has stored therein a plurality of objects comprising a plurality of language objects and a plurality of frequency objects, at least some of the language objects each being associated with a frequency object, and wherein the operations further comprise outputting the numeric interpretation as the default portion responsive at least in part to an absence of a language object that matches the series.

18. The handheld electronic device of Claim 11 wherein the memory has stored therein a plurality of objects comprising a plurality of language objects and a plurality of frequency objects, at least some of the language objects each being associated with a frequency object, and wherein the operations further comprise:

- making a determination that no language object corresponds with the series;
- employing the making of the determination as one of the number of predetermined events; and
- outputting as an interpretation of the series a disambiguated text interpretation of the initial input member actuations plus a symbol character assigned to the current input member.

19. The handheld electronic device of Claim 11 wherein the operations further comprise:

- making a determination that the current input member actuation is a press-and-hold actuation of a predetermined duration;
- employing the making of the determination as one of the number of predetermined events; and
outputting as a proposed interpretation of the series a disambiguated text interpretation of the initial input member actuations and a symbol character assigned to the current input member.

20. The handheld electronic device of Claim 19 wherein the operations further comprise:

outputting in a list the proposed interpretation and a number of disambiguated text interpretations of the series; and

outputting the proposed interpretation in the list at a position of relatively higher priority than at least some of the disambiguated text interpretations.
