The invention relates to a method for making a lignin component from lignin material by an acid treatment, the method comprising: forming a lignin component of lignin material by treating the lignin material in at least one acid treatment stage; and optimizing process conditions by means of a combination of process parameters comprising retention time, temperature and pH level at the acid treatment stage so that the retention time is over 6 hours during at least one acid treatment stage. Further, the invention relates to corresponding lignin components, a use of the lignin component and a product.
A METHOD FOR MAKING A LIGNIN COMPONENT, A LIGNIN COMPONENT AND ITS USE AND A PRODUCT

FIELD OF THE INVENTION

The invention relates to a method for manufacturing a lignin component. Further, the invention relates to a lignin component and a use of the lignin component. Further, the invention relates to a product.

BACKGROUND OF THE INVENTION

Known from publication WO 2006/031175 is a method for separation of lignin from black liquor.

OBJECTIVE OF THE INVENTION

The objective of the invention is to disclose a new method for manufacturing a lignin component. Another objective of the invention is to produce a lignin component with improved properties and a product comprising the lignin component.

SUMMARY OF THE INVENTION

The method for making a lignin component from a lignin material according to the present invention is characterized by what is presented in claims.

The lignin component according to the present invention is characterized by what is presented in claims.

The use of the lignin component according to the present invention is characterized by what is presented in claims.

The product according to the present invention is characterized by what is presented in claims.
BRIEF DESCRIPTION OF THE FIGURES

The accompanying figures, which are included to provide a further understanding of the invention and constitutes a part of this specification, illustrate some embodiments of the invention and together with the description help to explain the principles of the invention. In the figures:

Fig. 1 is a flow chart illustration of a method according to one embodiment of the present invention,

Fig. 2 is a flow chart illustration of a method according to another embodiment of the present invention,

Fig. 3 is a flow chart illustration of a method according to another embodiment of the present invention,

Fig. 4 is a flow chart illustration of a method according to another embodiment of the present invention,

Fig. 5a and 5d show lignin structures in cakes of comparative lignin components,

Fig. 5b and 5c show lignin structures in cakes of lignin components according to the present invention,

DETAILED DESCRIPTION OF THE INVENTION

In the method of the present invention a lignin component is made from lignin material by an acid treatment, the method comprising: forming a lignin component of lignin material by treating the lignin material in at least one acid treatment stage; and optimizing process conditions by means of a combination of process parameters comprising retention time, temperature and pH level at the acid treatment stage so that the retention time is over 6 hours during at least one acid treatment stage.

One embodiment of the method of the present invention is shown in figure 1. Another embodiment of the method of the present invention is shown in figure 2. Another embodiment of the method of the present invention is shown in figure 3. Another embodiment of the method of the present invention is shown in figure 4. Further, lignin structures in cakes of lignin components are shown in figures 5a - 5d.

In the method of the present invention a lignin component is made from a lignin material (1) by a mild acid treatment. According to the invention, a lignin component (3) is formed of lignin material so that the lignin material (1) is treated in at least one acid treatment stage (2a, 2b) and the at least one acid treatment stage is optimized by means of a combi-
nation of process parameters comprising retention time, e.g. long retention time, temperature, e.g. high temperature, and pH level, e.g. sufficient low, in order to decrease ash and/or carbohydrates in the lignin component, and preferably in order to remove undesired substance from the lignin component and to purify the lignin component.

The invention is specially based on improving properties of the lignin component. When the lignin material is acid treated at one or more acid treatment stage by optimizing retention time, temperature and pH level, then the properties, such as purity, dry solids content, filterability, amounts of carbohydrates and ash, of the lignin component can be improved. Further, odour in the lignin component can be decreased. Then it is provided the lignin component which is suitable to use in typical and special applications.

In this context, a lignin material refers any material or composition containing lignin. The lignin material may contain one or more material components. In one embodiment suitable and desired additives can be added into the lignin material to form a desired lignin component.

In one embodiment the lignin material includes material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material by a solution including suitable chemicals and their combinations.

In one embodiment the lignin material includes flash precipitated lignin. In one embodiment flash precipitated lignin is obtained after CO₂-precipitation. Preferably, flash precipitated lignin is formed as disclosed in patent application PCT/FI2011/050896.
In one embodiment the lignin is precipitated from the black liquor by a continuous process with \( \text{CO}_2 \) at 3 - 8 bar overpressure. In one embodiment the lignin is separated by a flash precipitation lignin separation method, such as disclosed in patent application PCT/FI2011/050896. In one embodiment of the present invention the lignin is flash precipitated lignin. The term "flash precipitated lignin" should be understood in this specification as lignin that has been precipitated from black liquor in a continuous process by decreasing the pH of a black liquor flow, under the influence of an over pressure of 200 - 1000 kPa, down to the precipitation level of lignin using a carbon dioxide based acidifying agent, preferably carbon dioxide, and by suddenly releasing the pressure for precipitating lignin. The residence time in the above method is under 300 s. The flash precipitated lignin particles, having a particle diameter of less than 2 \( \mu \text{m} \), form agglomerates, which can be separated from black liquor using e.g. filtration. The flash precipitated lignin can be purified and/or activated if needed for the further processing. The flash precipitated lignin has many advantages, e.g. activity, dispersability, solubility, drainability and preservability. In one embodiment of the present invention, the lignin component is a flash precipitated kraft lignin. Preferably, the flash precipitated kraft lignin is undrained. Therefore the lignin has higher activity, and the lignin can be re-dissolved. The lignin needs only a very simple re-dispersing stage when it is added e.g. into an adhesive mixture. Also control of the amount of water in the lignin based composition is easier when the re-dispersing is easier. Further, the lignin is easier to handle in the process because the lignin is not dusty. Preferably, the flash precipitated kraft lignin has dry matter content of 50 - 80 \%.
In one embodiment the lignin material is treated chemically and/or mechanically before the at least one acid treatment stage of the present invention. In one embodiment the lignin material is precipitated before the at least one acid treatment stage. In one embodiment the lignin material is re-slurried before the at least one acid treatment.

In this context, a lignin component means product formed from lignin material in at one or more stages. Term "lignin component" is already used after the first treatment stage.

In this context, a carbohydrate refers any carbohydrates, especially hemicellulose.

In one embodiment the at least one acid treatment stage is acid washing (2a). In the acid washing an amount of ash can be decreased in the lignin component. Further, in the acid washing filterability of the lignin component can be enhanced. Further, in the acid washing dry solids content of the lignin component can be improved. Improved dry solid content of filter cake leads to lower energy consumption in drying and to lower consumption of water in washing to reach same purity. Also dryer can be smaller, which leads to savings in investment. Savings in water consumption is important, since likely washing water must be circulated back to evaporation plant. Also certain dry solid content is needed to maintain processability of lignin cakes. For applications requiring no drying, for example burning, the low content of water in filter cake is a benefit.

In one embodiment the at least one acid treatment stage is acid hydrolysis (2b). In the acid hydrolysis an amount of carbohydrates can be decreased in the lignin component. Further, in the acid hydrolysis an amount of ash can be still decreased in the lignin component. It is important that lignin softens
before or during acid hydrolysis; then carbohydrates can be removed from the lignin component and the lignin component can be purified. The softening is preferably performed slowly in correct temperature to prevent condensation of lignin and formation of char. The softening can be carried out at wide pH range.

In one embodiment the lignin material (1) is treated at two acid treatment stages in which first stage is acid washing (2a) and second stage is acid hydrolysis (2b). The first stage can be a typical acid washing. Preferably, the second stage is a purification stage.

In this context, the acid washing refers to any acid washing method. In one embodiment the acid washing is performed with H₂SO₄, other acid or other suitable acidifying chemical. The optimization of the invention affects positively consumption of H₂SO₄ or other acid or other acidifying chemical.

In this context, the acid hydrolysis refers to any acid hydrolysis method. In one embodiment the acid hydrolysis is performed by means of H₂SO₄, or other suitable acidifying chemical, typically in the presence of water.

In one embodiment the lignin material is treated in the at least one acid treatment stage with H₂SO₄.

In one embodiment the method comprises two acid treatment method steps. In one embodiment the first step is a removal of ash and the second step is a removal of carbohydrates. In one embodiment the first step is an increasing of dry solids content in the lignin component and the second step is a removal of carbohydrates from the lignin component. In one embodiment the first step comprises a removal of ash and increasing of dry solids content in the lignin component, and the second step is a removal of carbohydrates from the lignin component.
In one embodiment the method comprises a pre-treatment step before the at least one acid treatment stage. In one embodiment the lignin material is re-slurried in the pre-treatment step. In a preferred embodiment the pre-treatment step is a softening step of lignin in which the lignin is softened and structure of the lignin is modified. An acid is able to hydrolyze carbohydrates in lignin after the softening step.

Preferably, in each acid treatment stage of the invention a suitable combination of temperature, retention time and pH level is selected. The selected combination varies based on acid washing or acid hydrolysis. The process conditions are selected such that lignin does not alternate into carbon or char during the acid treatment.

Preferably, long retention time is used in the acid treatment according to the invention. In one embodiment the retention time is over 1 hour. In one embodiment the retention time is over 4 hours, preferably over 6 hours, and more preferably over 8 hours. In one embodiment the retention time is over 16 hours.

In this context, retention time means time of the treatment stage. The retention time does not include a filtration time.

In one embodiment the temperature is over 60 °C during the treatment stage. In one embodiment the temperature is over 70 °C, preferably over 72 °C, more preferably over 73 °C, and most preferably over 75 °C.

In a preferred embodiment pH level is sufficient low during the treatment stage. In one embodiment the pH level is under 3.5, preferably between 2 - 3. In one embodiment the pH level is under 2.0, preferably between 0.5 - 1.5. In one embodiment the pH level which is between 2 - 4 can be used.

In one embodiment the pH level is between 0.5 - 4.0, preferably 0.8 - 1.5, the temperature is be-
between 80 - 130 °C, preferably 80 - 105 °C, and the retention time is between 2 - 60 hours, preferably 6 - 30 hours, at the at least one acid treatment stage, e.g. at the acid hydrolysis stage. Temperature is below glass transition point of lignin.

In one embodiment the pH is between 2.5 - 3.5, temperature is between 65 - 80 °C, preferably between 70 - 80 °C and more preferable about 70 °C, and retention time is over 1 hour at the acid washing stage. Increasing temperature and/or retention time and/or decreasing pH level dry solid content and filterability may be improved.

In one embodiment the lignin material is treated in the at least one acid treatment stage and the at least one acid treatment stage is optimized by means of process parameters selected from retention time, temperature, pH level, mixing, oxidizing and their combinations. In one embodiment combination of selected process parameters is optimized in the at least one acid treatment stage. In one embodiment combination of selected process parameters is optimized in each acid treatment stage.

In one embodiment the acid treatment stage is adjusted by means of process parameters in order to increase low molecular weight lignin fragments. If harsh reaction conditions, e.g. temperature over 70 °C, retention time over 8 hours and pH level between 1 - 1.5, is applied in the acid hydrolysis then low molecular weight lignin can be obtained with improved yield.

In one embodiment, when the pre-treatment is made before the acid treatment so in the pre-treatment retention time is below 2 hours, temperature is between 55 - 70 °C and pH is between 9 - 10.5. In one embodiment, when the pre-treatment is made before the acid treatment so in the pre-treatment retention time
is below 2 hours, temperature is between 55 – 75 °C and pH is between 9 – 10, and in the acid treatment retention time is over 8 hours, temperature is between 70 – 80 °C and pH is below 3.5. In an alternative embodiment, when the pre-treatment is made before the acid treatment so in the pre-treatment retention time is over 8 hours, temperature is between 60 – 75 °C and pH is between 9 – 10, and in the acid treatment retention time is below 2 hours, temperature is between 65 – 80 °C and pH is below 3.5.

It is important for the invention that long retention time is used at least in one stage. Alternatively, the long retention time can be used in more than one stage. The long retention time can be used at the acid treatment stage, e.g. in the acid washing and/or in the acid hydrolysis, and/or in the pre-treatment step.

In one embodiment the formed lignin component (3) is filtrated at the filtration stage (4a, 4b) after at least the latest acid treatment stage (2a, 2b). In one embodiment the formed lignin component is filtered after each of the at least one acid treatment stages.

In this context, the filtration refers to any filtration method which can be used in the filtration of the lignin. Preferably, in the filtration the lignin component is washed by water and pressed and optionally air-dried. The filtration can be performed by any suitable filtration device. In one embodiment the formed lignin component is filtrated by pressure filtration or vacuum filtration. In one embodiment pressure is between 10 – 20 bar, preferably 13 – 17 bar and more preferable about 15 bar in the pressure filtration.

Preferably improved filterability, especially better filtration rate, achieved by means of the optimi-
ORIZATION leads to smaller pressure requirement in the filtration and to shorter filtration time. Then cheaper filters, e.g. based on size and type of device, may be used.

In one embodiment the pH level is adjusted just before the filtration, especially if shorter retention time is used in the acid treatment stage. In one embodiment temperature is over 50 °C and pH is between 2 to 4 during the filtration.

In one embodiment the lignin material is treated in the at least one acid treatment stage such that dry solids content of the lignin component can be increased over 5 %, preferably 5 - 15 %, more preferably about 10 - 15 %, as compared with standard lignin component formed by a known acid washing method. In one embodiment dry solids content of the lignin component is over 60 %, preferably over 70 %, more preferably between 70 - 90 % and most preferably between 70 - 80 %.

In one embodiment the lignin material is treated in the at least one acid treatment stage such that carbohydrates content of the lignin component is under 1.0 %, preferably under 0.5 %, more preferably under 0.2 % and most preferably under 0.1 %.

In one embodiment the lignin material is treated in the at least one acid treatment stage such that ash content of the lignin component is under 1.0 %, preferably under 0.5 %, more preferably under 0.2 % and most preferably under 0.1 %.

In one embodiment proportion of lignin dissolved during the at least one acid treatment stage is adjusted by means of process parameters selected from retention time, temperature, pH level, mixing efficiency, mixer type, oxidation and their combinations. Then low molecular weight lignin component can be
achieved. In one embodiment proportion of lignin dissolved is adjusted during the acid hydrolysis stage.

In one embodiment the additional oxidation is made after the filtration in which an acidic filtrate is additionally oxidized.

In one embodiment the lignin component is additionally oxidized during the acid treatment stage, e.g. at the acid hydrolysis stage. The additional oxidation may be performed by means of air, oxygen, other oxidizing agent or their combinations in order to stabilize structure of the lignin component, to increase purity of lignin and to remove odour.

The lignin component (3) obtainable by the method of the present invention can be used as component in manufacturing a final product selected from activated carbon, carbon fiber, lignin composite, e.g. lignin-plastic composite or lignin-fiber composite, binder material, phenolic component, dispersion agent and their combinations.

The final product or product comprises the lignin component of the present invention. Preferably, pure lignin component according to the present invention is needed in the manufacturing of the activated carbon and carbon fibers.

The method according to the present invention provides the lignin component with good quality. When improving the purify and increasing dry solids content of the lignin component so then it may be provided better properties of the lignin component and the final product.

The present invention provides an industrially applicable, simple and affordable way of making the lignin component from the lignin material. The method according to the present invention is easy and simple to realize as a production process. The method according to the present invention is suitable for use in
the manufacture of the different lignin components from different lignin materials.

The invention is described in more detail by the following examples 1 - 6 with reference to accompanying figures 1 - 4 and 5a-d.

Example 1

In this example and in figure 1, a lignin component (3) is formed by an acid treatment.

A starting lignin material (1), which is flash precipitated lignin, is treated by two acid treatment stages (2a, 2b). The first stage (2a) is an acid washing stage and the second stage (2b) is an acid hydrolysis stage. Process conditions are following at the first stage: temperature about 70 °C, retention time over 1 hour and pH level about 3. The acid washing is performed with \( \text{H}_2\text{SO}_4 \). Process conditions are following at the second stage: temperature over 70 °C, retention time over 8 hours and pH level between 1 - 1.5. The acid treating in hydrolysis is performed with \( \text{H}_2\text{SO}_4 \).

The lignin component (3) is filtrated after each acid treatment stage (2a, 2b) by pressure filtration (4a, 4b). Temperature is over 50 °C and pH is about 2 to 4 during the filtration.

The lignin component can be additionally oxidized during the acid treatment stage.

In these tests it was discovered that it may be produced the lignin component with excellent properties. The formed lignin component has low ash and carbohydrates contents. It was discovered that the ash content can be reduced during the first stage. Further, the ash content can be still reduced during the second stage. It was discovered that the carbohydrates content can be mainly reduced during the second stage but a part of carbohydrates can be reduced during the
By means of high temperature, long retention time and low pH lignin is softened. After softening, acid is able to hydrolyze carbohydrates and oxidize accessible part of lignin into soluble compounds. Carbohydrates may be removed during the acid treatment.

Further, it was discovered that dry solids content of the final lignin component cake can be increased and filterability can be enhanced already at the first stage. Dry solids content of the lignin component can be increased over 5% as compared with standard lignin component. The lignin component has ash content below 0.1% and carbohydrates content below 0.2%. Further, at least part of inorganic sulphur was removed at the acid hydrolysis stage. Further, by means of acid hydrolysis may be increased glass transition temperature of lignin and/or decomposition temperature of lignin.

Further, it is discovered that lignin structure in the cake of the lignin component was in the form of big-single particles. This explains good filterability and high dry solids content.

Further, in these tests it was discovered that the special good optimization results were achieved by two stages process.

**Example 2**

In this example and in figure 2 a lignin component (3) is formed by an acid treatment.

A starting lignin material (1) is treated by one acid treatment stage which is an acid washing stage (2a). Process conditions are following: temperature is about 70 °C, retention time over 1 hour and pH level is about 3. The acid washing is performed with H₂SO₄.
The lignin component (3) is filtrated after acid washing by pressure filtration (4a). Temperature is over 50 °C and pH is about 2 to 4 during the filtration.

In these tests it was discovered that the formed lignin component has low ash content but carbohydrates content has not decreased, such as in example 1. It was discovered that the ash content can be reduced during the acid washing.

**Example 3**

In this example and in figure 3, a lignin component (3) is formed by an acid treatment.

A starting lignin material (1) is treated by one acid treatment stage which is an acid hydrolysis (2b). Process conditions are following: temperature over 70 °C, retention time over 8 hours and pH level between 1 - 1.5.

The lignin component (3) is filtrated after acid hydrolysis by pressure filtration (4b). Temperature is over 50 °C during the filtration.

In these tests it was discovered that it may be produced the lignin component with good properties. The formed lignin component has low ash and carbohydrates contents. It was discovered that the ash content and carbohydrates content can be reduced during the acid hydrolysis.

**Example 4**

In this example and figure 4, a lignin component (3) is formed by an acid treatment.

A starting lignin material (1) is treated firstly at a pre-treatment stage (5) in which is made a re-slurry step, and secondly at an acid washing stage (2a) in order to produce a lignin component. Af-
ter the acid washing the lignin component is filtrated (4a).

In the tests 1 - 4 the pre-treatment is carried out so that short retention time and high pH are used. Then, in the acid washing long retention time and low pH are used.

In the tests 5 and 6 the pre-treatment is carried out so that long retention time and high pH are used. In the acid washing shorter retention time and low pH, about 2.5, are used. It was discovered that during the pre-treatment of tests 5 and 6 softening and particle growth of the lignin is happened thanks to long retention time. Therefore, shorter retention time is sufficient in the acid washing.

Process conditions are described in table 1.

In these tests it was discovered that it may be produced the lignin component with good cake dry matter. In tests 1 - 4 it was discovered that the cake dry matter can be increased when the temperature of the acid washing was over 70 °C, retention time of the acid washing was long and pH was low, about 2.5.

Further, in tests 5 - 6 it was discovered that the cake dry matter can be increased when the temperature of the pre-treatment was over 70 °C and retention time of the pre-treatment was long.

It was discovered that it is important for the invention that long retention time and temperature over 70 °C are used in at least one acid treatment stage.

Two lignin components of the present invention have been shown in figures 5b (Test 2) and 5c (Test 5) (SEM images). By way of comparison figures 5a (Test 1) and 5d (Test 6) (SEM images) show structures of comparative lignin components. Improvements in filterability and cake dry matter between Test 1 and Test 6 is mainly due to enhanced agglomeration. Improvement in cake dry matter between Test 6 and Tests 2 - 5 is due to softening of lignin and re-structure into bigger single particles.

**Example 5**

In this example and figure 2, a lignin component (3) is formed by an acid treatment.

A starting lignin material (1) is reslurried, and after then the lignin is treated at an acid treatment stage (2a) in order to produce a lignin component. After the acid treatment the lignin component is filtrated (4a).
Delay between the re-slurry and the acid treatment is about 1 hour and temperature is about 60 - 65 °C.

Process conditions of the acid treatment are described in table 2. In the tests 3 - 4 the acid treatment is carried out so that long retention time and low pH are used. Tests 1 and 2 are comparative tests. In test 1 low temperature and short retention time are used. In test 2 low temperature and long retention time are used.

in which T2b is temperature of the acid hydrolysis
t2b is retention time of the acid hydrolysis
Tfilt is temperature of the filtration

Test 9 with T2b of 140 °C, t2b of 1 hour and
pH of 3.5 resulted in the formation of char, which ad-
hered to reactor walls.

In these tests of examples 1 - 6 it was dis-
covered that it may be produced the lignin component
with good ash content and carbohydrates content.
Starting lignin material for the hydrolysis tests, so
Test 5 in Table 1 had carbohydrates content of 0.73 %.
In tests it was discovered that the ash and carbohy-
drates content can be decreased when the temperature
of the acid hydrolysis was high, over 75 °C, retention
time of the acid hydrolysis was long and pH was low.
Long retention time in the acid washing stage shortens
the time needed in the acid hydrolysis stage. Molecu-
lar weight of the lignin after the acid hydrolysis re-
veals that extensive condensation was not encountered.
The consumption of sulphuric acid increases rapidly
when pH is below 1.

One embodiment of the method of the present in-
vention is shown in figure 6. Another embodiment of the
method of the present invention is shown in figure 7. A
structure of one lignin component is shown in figure 8.

The invention relates to optimization of acid
treating in lignin separation process. In the method
of the present invention a lignin component is formed
from a lignin material by an acid treatment, the method comprising: forming a lignin component (3) of lignin material (1) by treating the lignin material in an acid treatment stage (2) by means of an acid composition; and optimizing process conditions in the acid treatment stage (2) so that high temperature over 70 °C, long retention time, such as delay time, over 6 hours and pH level between 4.5 - 7 are used during the acid treatment in order to remove undesired substance from the lignin component and to purify the lignin component and to reduce acid consumption in the acid treating of lignin.

In a preferred embodiment the lignin material (1) is treated by an acid washing (2) to form a lignin component (3). The lignin material (1) is treated in an acid washing stage (2). Long retention time over 6 hours, high temperature over 70 °C, and pH level between 4.5 and 7 are used in the acid washing.

The invention is specially based on improving properties of the lignin component. When the lignin material is acid treated by optimizing process conditions and parameters, e.g. retention time and temperature, then higher pH level, e.g. 4.5 - 7 instead of about 2.5, can be used, and then the properties, such as purity, dry solids content and filterability of the lignin component are good. Further, acid such as virgin acid consumption can be decreased. Preferably, destabilisation of lignin happens before the filtration thanks to high temperature and long retention time in the acid treatment. Further, odour in the lignin component can be decreased. Then it is provided the lignin component which is suitable to use in typical and special applications.

In this context, a lignin material refers any material or composition containing lignin. The lignin material may contain one or more material components. In one embodiment suitable and desired additives can
be added into the lignin material to form a desired lignin component.

In one embodiment the lignin material includes material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material by a solution including suitable chemicals and their combinations.

In one embodiment the lignin material includes flash precipitated lignin. In one embodiment flash precipitated lignin is obtained after C\textsubscript{2}O\textsubscript{2}-precipitation. Preferably, flash precipitated lignin is formed as disclosed in patent application PCT/FI2011/050896.

In one embodiment the lignin is precipitated from the black liquor by a continuous process with C\textsubscript{2}O\textsubscript{2} at 6 - 10 bar overpressure. In one embodiment the lignin is separated by a flash precipitation lignin separation method, such as disclosed in patent application PCT/FI2011/050896. In one embodiment of the present invention the lignin is flash precipitated lignin. The term "flash precipitated lignin" should be understood in this specification as lignin that has been precipitated from black liquor in a continuous process by decreasing the pH of a black liquor flow, under the influence of an over pressure of 200 - 1000 kPa, down to the precipitation level of lignin using a carbon dioxide based acidifying agent, preferably carbon dioxide, and by suddenly releasing the pressure for precipitating lignin. The residence time in the above method is under 300 s. The flash precipitated lignin particles, having a particle diameter of less than 2 \(\mu\text{m}\), form agglomerates, which can be separated from black liquor using e.g. filtration. The flash precipitated lignin can be purified and/or activated if needed for the
further processing. The flash precipitated lignin has
many advantages, e.g. activity, dispersability, solu-

bility, drainability and preservability. In one embod-
iment of the present invention, the lignin component
is a flash precipitated kraft lignin. Preferably, the
flash precipitated kraft lignin is undrained. There-
fore the lignin has higher activity, and the lignin
can be re-dissolved. The lignin needs only a very sim-
ple re-dispersing stage when it is added e.g. into an
adhesive mixture. Also control of the amount of water
in the lignin based composition is easier when the re-
dispersing is easier. Further, the lignin is easier to
handle in the process because the lignin is not dusty.
Preferably, the flash precipitated kraft lignin has
dry matter content of 50 - 80%.

In one embodiment the lignin material is
treated chemically and/or mechanically before the acid
treatment stage of the present invention. In one embod-
iment the lignin material is precipitated before the
acid treatment stage. In one embodiment the lignin ma-
terial is re-slurried before the acid treatment.

In this context, a lignin component means
product formed from lignin material in one or more
stages. Term "lignin component" is already used after
the first treatment stage.

In this context, the acid washing refers to
any acid washing method. In one embodiment the acid
washing is performed with an acid composition contain-
ing sulphuric acid (H₂SO₄), other acid or other suita-
ble acidifying chemical or their combination. The op-
timization of the process affects positively consump-
tion of H₂SO₄ or other acid or other acidifying chemi-
cal.

In one embodiment the acid composition con-
tains sulphuric acid, which can be virgin acid or re-
cycled acid. Without any process improvements accord-
ing to the invention consumption of sulphuric acid is rather high. Sulphuric acid is cheap, but high amount of sodium hydroxide is needed to fulfil Na/S balance of pulp mill. Furthermore, all extra sulphur added to process must be dumped from recovery boiler meaning extra cost.

In a preferred embodiment the acid composition contains other acid or other acidifying chemical containing salt. Salt can be selected from group K-, Na-, Mg-, Al-, Ca-salt or other suitable salt. In one embodiment the acid composition contains sulphate compound with salt. In one embodiment the acid composition contains sodium sesquisulphate. Sodium sesquisulphate (SSS) is a waste fraction from chlorine dioxide plant in pulp mill. In one embodiment waste acid is used as other acid or other acidifying chemical.

Preferably the acid composition contains sulphuric acid, and other acid or other acidifying chemical with salt. In one embodiment the acid composition contains sulphuric acid and sodium sesquisulphate. In one embodiment the acid composition contains sulphuric acid about 10 - 90 w-%, in one embodiment 60 - 70 w-%, and sodium sesquisulphate about 10 - 90 w-%, in one embodiment 30 - 40 w-%. The high pH saves acid or other acidifying chemical containing salt which is good for the pulp mill and brings less salt to process, and then less water is needed for washing.

Preferably, in the acid treatment stage of the invention a suitable combination of temperature, retention time and pH level is selected. The selected combination varies based on acid washing method, lignin material, acid composition and desired product.

Preferably, long retention time is used in the acid treatment according to the invention. In one embodiment the retention time is over 6 hours, prefer-
ably over 10 hours, and more preferable between 10 and 20 hours.

In this context, retention time means time of the treatment stage. The retention time does not include a filtration time.

In one embodiment the temperature is over 80 °C during the acid treatment stage, preferably over 85 °C, and more preferable between 80 - 90 °C.

In a preferred embodiment pH level is sufficient high during the acid treatment stage. In one embodiment the pH level is over 4.5, preferably over 5. In one embodiment the pH level is under 7, preferably under 6. In a preferred embodiment the pH level which is between 5 and 6 can be used. When high pH is used according to the invention, so it leads to non-corrosive lignin as a product. Then stainless steel instead of more expensive acid-proof steel can be used in the process devices.

In one embodiment the pH level is between about 4.5 - 7, preferably about 5 - 6, the temperature is between 70 - 100 °C, preferably 80 - 90 °C, and the retention time is over 1 hour, preferably 6 - 30 hours and more preferable between 10 and 20 hours, at the acid treatment stage.

Increasing temperature and/or retention time and/or pH level dry solid content and filterability may be improved. Improved dry solid content of filter cake leads to lower energy consumption in drying and to lower consumption of water in washing to reach same purity. Also dryer can be smaller, which leads to savings in investment. Savings in water consumption is important, since likely washing water must be circulated back to evaporation plant. Also certain dry solid content is needed to maintain processability of lignin cakes. For applications requiring no drying,
for example burning, the low content of water in filter cake is a benefit.

In the present invention it has been noticed that use of high temperature and long delay time combined with high pH, e.g. 5 - 7, and use of sodium sesquisulphate can reduce acid consumption even by about 65 %, which means acid consumption of about 70 kg/t lignin. In the process of the invention normal cake washing with water after the acid treatment is enough to raise or keep pH of final lignin to between 5 and 7.5, preferably 6 - 7. Then lignin is non-corrosive. Production of neutral lignin is necessity for most applications. If lignin has pH of 2.5, so an additional process stage is needed to neutralize lignin.

The method of the invention can be used in connection with any acid treatment process containing one or more acid treatment stages. In one embodiment the acid treatment process comprises acid hydrolysis stage before or after the acid washing stage.

The method of the invention can be used in connection with the acid treatment process described in patent application FI20116253.

In one embodiment the method of the present invention comprises a pre-treatment step (5) before the acid treatment stage (2). In one embodiment the lignin material is re-slurried in the pre-treatment step. In a preferred embodiment the pre-treatment step is a softening step of lignin in which the lignin is softened and structure of the lignin is modified.

In one embodiment, when the pre-treatment (5) is made before the acid treatment so in the pre-treatment retention time is below 2 hours, temperature is between 55 - 70 °C and pH is between 9 and 10.5.

It is important for the invention that long retention time is used at the acid treatment. Alternatively, the long retention time can be used also in
other stage such as in the pre-treatment stage. The long retention time can be used in the acid washing and/or in the pre-treatment step.

In one embodiment the formed lignin component (3) is filtrated at the filtration stage (4) after the acid treatment stage (2).

In this context, the filtration refers to any filtration method which can be used in the filtration of the lignin. Preferably, in the filtration the lignin component is washed by water and pressed and optionally air-dried. The filtration can be performed by any suitable filtration device. In one embodiment the formed lignin component is filtrated by pressure filtration or vacuum filtration. In one embodiment pressure is between 10 – 20 bar, preferably 13 – 17 bar and more preferable about 15 bar in the pressure filtration.

Preferably improved filterability, especially better filtration rate, achieved by means of the invention leads to smaller pressure requirement in the filtration and to shorter filtration time. Then cheaper filters, e.g. based on size and type of device, may be used.

In one embodiment temperature is over 50 °C and pH is between 5 and 7 during the filtration. In one embodiment the pH level is re-adjusted just before the filtration.

In one embodiment the process comprises at least two filtration stages. In one embodiment there is one filtration stage after each acid treatment stage. In one embodiment there is the first filtration stage before the acid washing of the invention and the second filtration stage after the acid washing of the invention. In the first filtration stage the lignin material or lignin component washed is filtrated at pH
about 10, and then sulphuric acid can be saved in the acid washing.

In one embodiment the additional oxidation is made after the filtration in which an acidic filtrate is additionally oxidized. In one embodiment the lignin component is additionally oxidized during the acid treatment stage. The additional oxidation may be performed by means of air, oxygen, other oxidizing agent or their combinations in order to stabilize structure of the lignin component, to increase purity of lignin and to remove odour.

The lignin component (3) obtainable by the method of the present invention can be used as component in manufacturing a final product selected from activated carbon, carbon fiber, lignin composite, e.g. lignin-plastic composite or lignin-fiber composite, binder material, phenolic component, dispersion agent and their combinations.

The final product or product comprises the lignin component of the present invention. Preferably, pure lignin component according to the present invention is needed in the manufacturing of the activated carbon and carbon fibers.

The method according to the present invention provides the lignin component with good quality. When improving the purify and increasing dry solids content of the lignin component so then it may be provided better properties of the lignin product and the final product.

The present invention provides an industrially applicable, simple and affordable way of making the lignin component from the lignin material. The method according to the present invention is easy and simple to realize as a production process. The method according to the present invention is suitable for use in
the manufacture of the different lignin components from different lignin materials.

Further, the invention is described in more detail by the following examples 7 – 8 with reference to accompanying figures 6 – 8.

Example 7

In this example and in figure 6, a lignin component (3) is formed by an acid treatment on a laboratory scale.

A starting lignin material (1), which was flash precipitated lignin, was re-slurred and treated by an acid washing stage (2). Process conditions were following at the acid washing stage: temperature about 87 °C, retention time about 12 hours and pH level about 5.6. The acid washing was performed with an acid composition containing H₂SO₄ and sodium sesquisulphate (SSS) so that mixture of H₂SO₄:SSS was 1:6. SSS was 20 % liquid.

The lignin component (3) was filtrated after the acid washing stage (2) by pressure filtration (4). Temperature was about 82 °C and pH was 6.5 – 7 during the filtration. Filtration rate was about 207 kg/m³/h. Dry solids content of filter cake was about 78 %.

In these tests it was discovered that it may be produced the lignin component with good properties. It was discovered that dry solids content of the final lignin component cake and filterability and filtration rate time needed were in good level. Further, sulphuric acid can be saved by means of the invention.

Further, it was discovered that lignin structure in the cake of the lignin component was in the form of big-single particles. This explains good filterability and high dry solids content.

Example 8
In this example a lignin component (3) is formed by an acid washing according to figure 6 on a pilot scale.

A starting lignin material (1), which was flash precipitated lignin, was slurred and was treated at an acid washing stage (2) by an acid composition in order to produce a lignin component. The acid washing was performed with an acid composition containing H₂SO₄ and sodium sesquisulphate (SSS) so that mixture of H₂SO₄:SSS was 1:6.

The lignin component (3) was filtrated after the acid washing stage (2) by pressure filtration (4). Temperature was about 82 °C and pH was 6.5 - 7 during the filtration.

Process conditions are described in table 4.

In the tests it was surprisingly discovered that filterability of the lignin component was good even though lignin component was treated in high pH level in the acid washing. In the tests it was discovered that to enable practical filtration rate, slurry of the lignin material must stay at pH 5 - 6 for sufficiently long time, over 6 hours and at sufficiently high temperature, over 70 °C, in the acid washing. Further, it was discovered that it may be produced the lignin component with good cake dry solids and quality. Further, it was discovered that high sodium concentration in the acid washing generally improves filtration, but usually raises final ash content in lignin component. However, ash content was at an adequate level.

Further, it was discovered that lignin structure in the cake of the lignin component was in the form of big-single particles. One lignin component of test 2 is shown in figure 8, SEM image.

From the all tests of examples 7 - 8 it was discovered that it is important for the invention that long retention time and high temperature together with
high pH level are used in the acid washing stage. Further, it was important that at least part of sulphuric acid is substituted by other acid or other acidifying chemical with salt. Sulphuric acid consumption can be decreased due to high pH level and substitution of sulphuric acid.

One embodiment of the method of the present invention is shown in figure 9. Another embodiment of the method of the present invention is shown in figure 10. One embodiment of the device of the present invention is shown in figure 11.

In the method of the present invention a lignin component is made from lignin material (1) by an acid treatment. According to the invention a lignin component (3) is formed of lignin material (1) by treating the lignin material by means of an acid composition in at least one acid treatment stage (2); and the lignin component is washed and neutralized (6) by a pH-buffer during a filtration (4) after the acid treatment, and pH in pH-buffer is between 4 - 10.

In this context, lignin material refers any material or composition containing lignin. The lignin material may contain one or more material components. In one embodiment suitable and desired additives can be added into the lignin material to form a desired lignin component.

In one embodiment the lignin material includes material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material by a solution including suitable chemicals and their combinations.

In one embodiment the lignin material includes flash precipitated lignin. In one embodiment flash precipitated lignin is obtained after C02-
precipitation. Preferably, flash precipitated lignin is formed as disclosed in patent application PCT/FI2011/050896.

In one embodiment the lignin is precipitated from the black liquor by a continuous process with CO₂ at 6-10 bar overpressure. In one embodiment the lignin is separated by a flash precipitation lignin separation method, such as disclosed in patent application PCT/FI2011/050896. In one embodiment of the present invention the lignin is flash precipitated lignin. The term "flash precipitated lignin" should be understood in this specification as lignin that has been precipitated from black liquor in a continuous process by decreasing the pH of a black liquor flow, under the influence of an over pressure of 200-1000 kPa, down to the precipitation level of lignin using a carbon dioxide based acidifying agent, preferably carbon dioxide, and by suddenly releasing the pressure for precipitating lignin. The residence time in the above method is under 300 s. The flash precipitated lignin particles, having a particle diameter of less than 2 µm, form agglomerates, which can be separated from black liquor using e.g. filtration. The flash precipitated lignin can be purified and/or activated if needed for the further processing. The flash precipitated lignin has many advantages, e.g. activity, dispersability, solubility, drainability and preservability. In one embodiment of the present invention, the lignin component is a flash precipitated kraft lignin. Preferably, the flash precipitated kraft lignin is undrained. Therefore the lignin has higher activity, and the lignin can be re-dissolved. The lignin needs only a very simple re-dispersing stage when it is added e.g. into an adhesive mixture. Also control of the amount of water in the lignin based composition is easier when the re-dispersing is easier. Further, the lignin is easier to
handle in the process because the lignin is not dusty. Preferably, the flash precipitated kraft lignin has dry matter content of 50 - 80%.

In one embodiment the lignin material is treated chemically and/or mechanically before the at least one acid treatment stage of the present invention. In one embodiment the lignin material is precipitated before the at least one acid treatment stage. In one embodiment the lignin material is re-slurried before the at least one acid treatment.

In this context, a lignin component means product formed from lignin material in at least one or more stages. Term "lignin component" is already used after the first treatment stage.

In one embodiment the at least one acid treatment stage (2) is selected from a group consisting of acid washing, acid hydrolysis and their combinations. The acid treatment (2) is carried at one stage or alternatively at more than one stage. In one embodiment the at least one acid treatment stage (2) is acid washing. In one embodiment the at least one acid treatment stage (2) is acid hydrolysis. In one embodiment the lignin material (1) is treated at two acid treatment stages (2) in which one of stages is acid washing and one of stages is acid hydrolysis.

In this context, the acid washing refers to any acid washing method. In one embodiment the acid washing is performed with an acid composition containing sulphuric acid ($H_2SO_4$), other acid or other suitable acidifying chemical or their combination. The optimization of the process affects positively consumption of $H_2SO_4$ or other acid or other acidifying chemical.

In this context, the acid hydrolysis refers to any acid hydrolysis method. In one embodiment the acid hydrolysis is performed by means of $H_2SO_4$, or oth-
er suitable acidifying chemical, typically in the presence of water.

In one embodiment the acid composition includes H₂SO₄ which can be virgin acid or recycled acid.

In one embodiment the acid composition includes acidifying chemical.

Preferably, in the acid treatment stage of the invention a suitable combination of temperature, retention time and pH level is selected. The selected combination varies based on acid washing or hydrolysis method, lignin material, acid composition and desired product.

Any acid treatment process can be used in connection with the present invention, for example acid treatment process as disclosed patent application FI20116253 or FI20125703 or other suitable acid treatment method can be used.

In one embodiment a lignin component is made from lignin material (1) by a mild acid treatment so that the lignin material (1) is treated in at least one acid treatment stage (2) and the at least one acid treatment stage is optimized by means of a combination of process parameters comprising retention time, e.g. long retention time, temperature, e.g. high temperature, and pH level, e.g. sufficient low, in order to decrease ash and/or carbohydrates in the lignin component, and preferably in order to remove undesired substance from the lignin component and to purify the lignin component. In one embodiment the lignin component is formed as disclosed in patent application FI 20116253.

In one embodiment the method comprising: optimizing process conditions in the acid treatment stage so that high temperature, long retention time and low pH level are used during the acid treatment.
Preferably, long retention time is used at the acid treatment stage, in at least one acid treatment stage. In this context, retention time means time of the acid treatment stage. The retention time does not include a filtration time.

In one embodiment the retention time which is over 6 hour is used during the acid treatment. Preferably, a lignin component is made from lignin material by an acid treatment, the method comprising: forming a lignin component of lignin material by treating the lignin material in at least one acid treatment stage; and optimizing process conditions by means of a combination of process parameters comprising retention time, temperature and pH level at the acid treatment stage so that the retention time is over 6 hours during at least one acid treatment stage.

In one embodiment the retention time which is over 8 hour is used during the acid treatment. In one embodiment the retention time which is over 10 hour is used during the acid treatment. In one embodiment the retention time which is over 16 hour is used during the acid treatment.

In one embodiment the temperature which is over 70 °C is used during the acid treatment. In one embodiment the temperature is over 72 °C, more preferable over 73 °C, and most preferable over 75 °C.

In one embodiment the pH level which is between 0.5 - 4 is used during the acid treatment. In a preferred embodiment pH level is sufficient low during the treatment stage. In one embodiment the pH level is under 3.5, preferable between 2 - 3. In one embodiment the pH level is under 2.0, preferably between 0.5 - 1.5. In one embodiment the pH level which is between 2 - 4 can be used.

In one embodiment the method comprises a pre-treatment step before the at least one acid treatment
stage. In one embodiment the lignin material is reslurried in the pre-treatment step. In a preferred embodiment the pre-treatment step is a softening step of lignin in which the lignin is softened and structure of the lignin is modified.

It is important for the invention that long retention time is used at least in one acid treatment stage. Alternatively, the long retention time can be used in more than one stage. The long retention time can be used at the acid treatment stage, e.g. in the acid washing and/or in the acid hydrolysis, and/or in the pre-treatment step.

Increasing retention time and/or temperature dry solid content and filterability may be improved. Improved dry solid content of filter cake leads to lower energy consumption in drying and to lower consumption of washing liquid in washing to reach good purify.

In one embodiment pH in pH-buffer is between 5 - 9. In one embodiment pH in pH-buffer is between 6 - 8. In one embodiment pH in pH-buffer is over 4, preferably over 5, and more preferable over 6. In one embodiment pH in pH-buffer is below 10, preferably below 9, and more preferable below 8. Highly alkaline washing liquid, in which pH is higher than 10, increases dissolution of lignin rapidly.

In one embodiment pH-buffer is in the form of solution.

The pH-buffer may include one or more than one component. Preferably, the pH-buffer contains at least one buffer agent. In one embodiment the pH-buffer includes buffer agent selected from a group consisting of citrate, acetate, carbonate and their combinations. In one embodiment the pH-buffer includes alkaline based compound, e.g. NaOH. In one embodiment the alkaline based compound is used to adjust pH level
in the pH-buffer. In one embodiment the pH-buffer includes citrate as a buffer agent. In one embodiment the pH-buffer includes citrate and alkaline based compounds and water, and pH of the pH-buffer is between 5 - 7. Alternatively, the pH-buffer can include any suitable buffer agent. In one embodiment the pH-buffer includes water. Composition of the pH-buffer can be optimized by taken into account the requirements of processes and final products.

Preferably, the method of the invention comprises the filtrating (4) of the lignin component after the acid treatment. In one embodiment the formed lignin component (3) is filtrated at the filtration stage (4) after at least the latest acid treatment stage (2).

In this context, the filtration refers to any filtration method which can be used in the filtration of the lignin. Preferably, in the filtration the lignin component is filtrated, washed and pressed and optionally air-dried. The filtration can be performed by any suitable filtration device. In one embodiment the formed lignin component is filtrated by pressure filtration or vacuum filtration. In one embodiment pressure is between 10 - 20 bar, preferably 13 - 17 bar and more preferable about 15 bar in the pressure filtration.

The filtration comprises a filtrating step, containing feeding of the lignin component, for forming a filter cake and washing step, such as a cake washing step, for washing the filter cake in order to decrease ash content in the lignin product. Further, the filtration may comprise a pre-pressing step before the washing step and a final pressing step after the washing step.

Preferably, the lignin component is neutralized during the filtration, preferably in connection with the
washing step, such as cake washing step. Preferably the washing of the lignin component is made by means of the pH-buffer. Simultaneously, the lignin component is neutralized. The pH-buffer is used instead of clean water when washing the filter cake.

In the present invention the filtration device (10) comprises a lignin feeding equipment for feeding the lignin component (7) from an acid treatment stage into the filtration device, and a filtering step for forming a cake of the lignin component and a washing step for washing the cake, and a pH-buffer feeding equipment (9) for feeding the pH-buffer (8) into the washing step. In the washing step the lignin component is washed and neutralized by the pH-buffer. Alternatively, the filtration device may comprise a pre-pressing step between the filtration step and the washing step and/or a final pressing step after the washing step. The pH-buffer feeding equipment (9) may contain one or more than one device selected from the group consisting of tank, pipe, pipeline, tube, pump and their combination or the like to feed the pH-buffer into the washing step.

In one embodiment the filtration device (10) comprises at least one feeding tank from which pH-buffer or component of the pH-buffer is fed into the washing step, into the pH-buffer feeding equipment or into a mixing device. In one embodiment the pH-buffer is fed from the feeding tank into the washing step by means of the pH-buffer feeding equipment. In one embodiment the pH-buffer feeding equipment contain at least one feeding tank. In one embodiment the pH-buffer is fed from the feeding tank into the washing step.

In one embodiment the filtration device (10) comprises a mixing device (11). In one embodiment the mixing device contains at least one mixing tank or at
least one mixer, e.g. static mixer, in a container or a pipeline in order to form the pH-buffer. The pH-buffer may be formed in the mixing device, e.g. in the mixing tank, by combining components of the pH-buffer together and/or by mixing. The pH-buffer is fed from the mixing device into the washing step by means of the pH-buffer feeding equipment or via the pH-buffer feeding equipment. Alternatively, the forming or mixing of the pH-buffer may be made in the pH-buffer feeding equipment, such as in the pipeline. In one embodiment the components of the pH-buffer is fed from the tanks into the feeding equipment for combining the components in the feeding equipment. In one embodiment the pH-buffer feeding equipment comprises the mixing device, e.g. static mixer in the pipeline.

In one embodiment the filtration device (10) comprises an adjustment device to adjust pH of the pH-buffer between 4 to 10, preferably before the washing step. In one embodiment pH of pH-buffer is analyzed by an analyzing device. In one embodiment the filtration device (10) comprises a controlling means to determine pH of the pH-buffer and/or adjust pH of the pH-buffer between 4 to 10, preferably before the washing step. In one embodiment the controlling means comprises at least one analyzing device. In one embodiment the controlling means comprises at least one adjustment device. In one embodiment the controlling means comprises at least one analyzing device and at least one adjustment device. The controlling means, adjustment device or analyzing device may be arranged in connection with the pH-buffer feeding equipment or mixing device. Alternatively, the controlling means, adjustment device or analyzing device may be arranged before the pH-buffer feeding equipment. In one embodiment the adjustment device contain means for adding pH-buffer into the washing step and/or means for adding buffer
agent into the pH-buffer. In one embodiment the adjustment device contain at least one adjustable valve for adjusting the feed of the pH-buffer into the washing step. In one embodiment the pH-buffer feeding equipment contain at least one adjustable valve for adjusting the feed of the pH-buffer into the washing step wherein the adjustable valve can be adjusted e.g. by means of controlling means or manually.

In one embodiment the forming of the pH-buffer is made as a batch process. In one embodiment the forming of the pH-buffer is made as a continuous process.

In one embodiment the filtration device comprises feeding tanks, a mixing device containing a mixing tank and a static mixer, and pH-buffer feeding equipment containing a pipeline and pump, and components of the pH-buffer from the feeding tanks and water are fed into the mixing tank in which the batch of the pH-buffer is formed by mixing with the static mixer, and the pH-buffer is fed from the mixing device into the washing step by means of the pH-buffer feeding equipment.

In one embodiment the filtration device comprises feeding tanks, pH-buffer feeding equipment containing a pipeline and pump, and a mixing device containing a static mixer in connection with the pH-buffer feeding equipment, and components of the pH-buffer from the feeding tanks and water are fed into the pipeline of the pH-buffer feeding equipment in which the pH-buffer is formed by mixing with the static mixer, and the pH-buffer is supplied into the washing step by the pump. Alternatively, components of the pH-buffer and water are not mixed in the pipeline when the pH-buffer is formed.

In one embodiment the pH-buffer is fed straightly, e.g. a feeding tank, into the washing step.
by means of the pH-buffer feeding equipment containing pipeline and pump.

In one embodiment temperature is over 50 °C during the filtration (4).

Preferably improved filterability, especially better filtration rate, achieved by means of the optimization leads to smaller pressure requirement in the filtration and to shorter filtration time. Then cheaper filters, e.g. based on size and type of device, may be used.

Preferably, pH of the lignin component is between 4 - 8 after the filtration (4), in one embodiment between 5 - 7. In one embodiment pH of the lignin component is over 5, in one embodiment over 6. In one embodiment pH of the lignin component is below 8, in one embodiment below 7. In a preferred embodiment pH of the lignin component is about 7.

In one embodiment the lignin component is dried after the filtration.

Further, the invention relates the lignin component which has specific properties, such as high particle size. Preferably, the lignin component has specific surface area between 0.1 - 1.0 m²/g, preferably between 0.2 - 0.7 m²/g, and more preferably between 0.3 - 0.6 m²/g. In the tests it is discovered that a particle size correlates with a specific surface area. Preferably, the lignin component has particle size which is bigger than in typical lignin products.

In one embodiment the lignin component is dried and/or grinded after the filtration. In one embodiment the lignin component which is dried and grinded into fine particles has bulk density between 200 - 800 g/cm³, preferably between 300 - 700 g/cm³, more preferably between 400 - 600 g/cm³, and in one embodiment about 500 g/cm³. In one embodiment the bulk
density is determined so that the lignin component is dried and grinded into fine particles, and after that the grinded lignin component is put into flexible intermediate bulk container, from which a sample is taken, and the bulk density of the lignin component is measured from the sample. Preferably, the bulk density of the lignin component of the present invention is bigger than in typical lignin products known in the art.

Further, the invention relates the lignin component which is formed from lignin material by an acid treatment, wherein a lignin component is formed of lignin material so that the lignin material is treated by means of an acid composition in at least one acid treatment stage; and the lignin component is washed and neutralized by a pH-buffer during a filtration after the acid treatment, and pH in pH-buffer is between 4 - 10.

Preferably ash content of the lignin component is low.

Further, the invention relates a use of the lignin component obtainable by the method of the invention, wherein the lignin component is used as component in manufacturing a final product selected from a group consisting of activated carbon, carbon fiber, lignin composite, binder material, phenolic component, dispersion agent and their combinations.

Further, the invention relates a product which includes the lignin component obtainable by the method of the invention. In one embodiment, the product is selected from a group consisting of activated carbon, carbon fiber, lignin composite, e.g. lignin-plastic composite or lignin-fiber composite, binder material, phenolic component, dispersion agent and their combinations.
The invention is specially based on improving properties of the lignin component. When the lignin material is acid treated at one or more acid treatment stage by optimizing retention time, temperature and pH level, then the properties, e.g. purity, dry solids content, filterability, amounts of carbohydrates and ash, of the lignin component can be improved. Further, odour in the lignin component can be decreased. Further, when the lignin component is neutralized then the neutral lignin component can be achieved. Then it is provided the lignin component which is suitable to use in typical and special applications.

The method according to the present invention provides the neutral lignin component with good quality, such as purify and dry solid content. When improving the purify and increasing dry solids content of the lignin component so then it may be provided better properties of the lignin product and the final product. The filterability of the lignin component and the operating costs at following process stages, e.g. in drying, are improved.

It is important that the neutral lignin component with purify properties is achieved. The neutral lignin component is non-corrosive. Then additional process stages are not needed to neutralize lignin, when clean water is replaced by pH-buffer during the washing. Neutralization of the lignin product in additional process stage is extremely difficult since after the separate neutralization stage a dewatering of the lignin product is difficult to make. The production of neutral lignin is necessity for most applications. Further, even burning of the lignin component benefits from non-corrosive nature of this biofuel. Non-corrosive lignin component can be fed in application process without need for stainless/acid-proof steel as material in feeding systems. Also, standard material can be used in storage.
The present invention provides an industrially applicable, simple and affordable way of making the lignin component from the lignin material. The method according to the present invention is easy and simple to realize as a production process. The method according to the present invention is suitable for use in the manufacture of the different lignin components from different lignin materials.

Further, the invention is described in more detail by the following examples 9 - 12 with reference to accompanying figures 9 - 11.

Example 9

In this example and in figure 9, a lignin component (3) is formed by an acid treatment.

A starting lignin material (1), which is flash precipitated lignin, is treated by one acid treatment stage (2), which is an acid washing stage. Process conditions are following: temperature is about 70 °C, retention time over 6 hour and pH level is about 3. The acid washing is performed with H₂SO₄.

The lignin component (3) is filtrated after the acid washing (2) by pressure filtration (4). Temperature is over 50 °C during the filtration. During the filtration (4), the washing and neutralization (6) of the lignin component is made by pH-buffer solution (8) containing citrate, acetate and/or carbonate as a buffer agent. pH of the pH-buffer solution is about 5 - 7.

The neutral lignin component is achieved. The lignin component has specific surface area between 0.1 - 1.0 m²/g.

Example 10
In this example and in figure 10, a lignin component (3) is formed by an acid treatment.

A starting lignin material (1), which is flash precipitated lignin, is treated firstly at a pre-treatment stage 5 in which a re-slurry step and filtration are made, and then at one acid treatment stage (2) which is an acid washing stage. Process conditions are following: temperature is about 70 °C, retention time over 6 hour and pH level is about 3. The acid washing is performed with H₂SO₄.

The lignin component (3) is filtrated after the acid washing (2) by pressure filtration (4). Temperature is over 50 °C during the filtration. During the filtration (4), the washing and neutralization (6) of the lignin component is made by pH-buffer solution (8) containing citrate, acetate and/or carbonate as a buffer agent. pH of the pH-buffer solution is about 6 - 7.

The neutral lignin component is achieved. The lignin component has specific surface area between 0.2 - 0.7 m²/g.

Example 11

In this example and in figure 11, a lignin component (7) formed by an acid treatment is filtrated by pressure filtration (4). Temperature is over 50 °C during the filtration. During the filtration (4), the washing and neutralization (6) of the lignin component is made by pH-buffer solution containing citrate as a buffer agent. pH of the pH-buffer solution is about 6 - 7.

The filtration, washing and neutralization is carried out in a filtration device (10). The filtration device (10) comprises a lignin feeding equipment for feeding the lignin component into the device, a filtrating step for forming a cake of the lignin com-
ponent, a washing step for washing the cake and a final pressing step for pressing. Alternatively, the filtration device may comprise a pre-pressing step between the filtration step and the washing step. A lignin component product (3) is formed during the filtration.

The pH-buffer solution is formed from buffer agent (12a) containing citrate agent, NaOH (12b) and water (13) by mixing in a mixing device (11) comprising a mixing tank or a mixer in a container or a pipeline. The pH-buffer solution (8) is fed by pH-buffer feeding equipment (9) containing a feeding pipeline and a pump into a washing step of the filtration device (10) for washing and neutralizing a cake of the lignin component (7). Alternatively, the mixing of the pH-buffer solution may be made in the feeding equipment, such as in the pipeline.

The lignin component (3) may be dried and grinded.

Example 12

In this example, pH of the lignin component product is determined after the filtration. The pH is measured from the lignin components of the present invention and reference samples.

The lignin components of the present invention have been formed by means of examples 9 and 11. During the filtration the lignin products washed by the pH-buffer in which pH was 6. The pH-buffer contained citrate agent (2.1 g/l citric acid), NaOH (pH 6) and water.

The reference samples have been formed by similar means than trial points. During the filtration the lignin products were washed by clean water.

In the filtration feeding, compression and cake washing times were similar when comparing water
and the pH-buffer in cake washing. pH of lignin based feed was about 2.5 before the filtration. Finally, a filter cake formed in the filtration was suspended in water (ds 25 %), mixed for 1 h at 60 °C, cooled to 25 °C and pH was measured.

Results are described in table 6.

It is discovered that pH of the lignin component can be increased by means of the method according to the present invention in comparison with reference samples.

Even when the pH of the pH-buffer was only 6, so lower than pH of clean water, the pH in the final lignin component was higher when the pH-buffer was used. This shows functionality of the invention. Ash and dry solids content of filter cake, time needed for cake washing and time needed for final pressing were similar to washing with clean water.

In these tests of examples 9 - 12 it was discovered that it may be produced the neutral lignin component with good properties, such as purify. It was discovered that dry solids content of the final lignin
component cake and filterability and filtration rate time needed were in good level.

Further, it was discovered that lignin structure in the cake of the lignin component was in the form of big-single particles. This explains good filterability and high dry solids content.

Further, the invention relates the lignin component which has specific properties, such as high particle size. Preferably, the lignin component has specific surface area between 0.1 - 1.0 m²/g, preferably between 0.2 - 0.7 m²/g, and more preferable between 0.3 - 0.6 m²/g. In the tests it is discovered that a particle size correlates with a specific surface area. Preferably, the lignin component has particle size which is bigger than in typical lignin products.

In one embodiment the lignin component is dried.

In one embodiment the lignin component is dried and/or grinded after the filtration. In one embodiment the lignin component which is dried and grinded into fine particles has bulk density between 200 - 800 g/cm³, preferably between 300 - 700 g/cm³, more preferable between 400 - 600 g/cm³, and in one embodiment about 500 g/cm³. In one embodiment the bulk density is determined so that the lignin component is dried and grinded into fine particles, and after that the grinded lignin component is put into flexible intermediate bulk container, from which a sample is taken, and the bulk density of the lignin component is measured from the sample. Preferably, the bulk density of the lignin component of the present invention is bigger than in typical lignin products known in the art.

Example 13
In this example, specific surface areas of lignin components are determined from the lignin component of the present invention and reference samples. The lignin components of the present invention have been formed by means of an acid treatment according to the present invention in which is used long retention time, over 6 h, and temperature over 70 °C. The reference samples have been formed by means of a typical acid treatment process in which is used low temperature and short retention time. Results are described in table 7.

</table>

The lignin component of the present invention has particle size which is bigger than in typical lignin products. It was discovered that a particle size correlates with a specific surface area.

In the present invention it is discovered that the ash content and carbohydrates content can be reduced during the acid hydrolysis without major influence on structure of lignin. It is well known from the prior art that the carbohydrates can be removed from lignin using
strong acid hydrolysis, but this will result in charring of lignin. Thanks to the invention the carbohydrates can be removed from lignin using mild conditions in the acid hydrolysis.

If lignin product has pH of 2.5, so an additional process stage may be needed to neutralize lignin product when close to neutral lignin is required in some downstream processing or applications. Separate neutralization stage would bring significant additional cost to process, since filtering of close to neutral lignin slurry is extremely slow by using standard methods. Clearly lower dry solids content of filter cake obtained after standard neutralization stage has biggest effect on raised operating costs. Thanks to the embodiments of the invention the neutral lignin product can be formed without separate neutralization stages.

The method according to the present invention is suitable in different embodiments to be used for making the most different kinds of lignin components from different lignin materials. The lignin component according to the present invention is suitable in different embodiments to be used in different final products.

The invention is not limited merely to the example referred to above; instead many variations are possible within the scope of the inventive idea defined by the claims.
CLAIMS

1. A method for making a lignin component from lignin material by an acid treatment, the method comprising:
   - forming a lignin component of lignin material by treating the lignin material in at least one acid treatment stage; and
   - optimizing process conditions by means of a combination of process parameters comprising retention time, temperature and pH level at the acid treatment stage so that the retention time is over 6 hours during at least one acid treatment stage.

2. The method according to claim 1, wherein the method comprising: forming a lignin component of lignin material by treating the lignin material in at least one acid treatment stage; and decreasing ash and/or carbohydrates in the lignin component by optimizing the at least one acid treatment stage by means of a combination of process parameters comprising retention time, temperature and pH level.

3. The method according to claim 2, wherein the at least one acid treatment stage is acid washing.

4. The method according to claim 2 or 3, wherein the at least one acid treatment stage is acid hydrolysis.

5. The method according to any one of claims 2 to 4, wherein the method comprising: treating the lignin material in two acid treatment stages in which the first stage is acid washing and the second stage is acid hydrolysis.

6. The method according to any one of claims 2 to 5, wherein the method comprising: treating the lignin material in the at least one acid treatment stage such that dry solids content of the lignin com-
ponent is increased over 5 % as compared with standard lignin component.

7. The method according to any one of claims 2 to 6, wherein the method comprising: treating the lignin material in the at least one acid treatment stage such that carbohydrates content of the lignin component is under 0.2 %.

8. The method according to any one of claims 2 to 7, wherein the method comprising: treating the lignin material in the at least one acid treatment stage with H₂SO₄.

9. The method according to any one of claims 2 to 8, wherein the retention time is over 1 hour.

10. The method according to any one of claims 2 to 9, wherein the temperature is over 70 °C.

11. The method according to any one of claims 2 to 10, wherein the pH level is between 0.5 - 1.5.

12. The method according to any one of claims 2 to 11, wherein the pH level is between 0.5 - 4.0, the temperature is between 80 - 130 °C and the retention time is between 2 - 60 hours at the at least one acid treatment stage.

13. The method according to any one of claims 2 to 12, wherein the method comprising: filtrating the lignin component after each of the at least one acid treatment stages.

14. The method according to any one of claims 13, wherein the method comprising: filtrating the lignin component by pressure filtration or vacuum filtration.

15. The method according to any one of claims 2 to 14, wherein the method comprising: adjusting the pH level just before the filtrating.

16. The method according to any one of claims 2 to 15, wherein the temperature is over 50 °C and the pH level is between 2 to 4 during the filtration.
17. The method according to any one of claims 2 to 16, wherein the method comprising: treating the lignin material in the at least one acid treatment stage; and optimizing the at least one acid treatment stage by means of process parameters selected from retention time, temperature, pH level, mixing, oxidizing and their combinations.

18. The method according to any one of claims 2 to 17, wherein the method comprising: adjusting proportion of lignin dissolved during the at least one acid treatment stage by means of process parameters selected from retention time, temperature, pH level, mixing efficiency, mixer type, oxidation and their combinations.

19. The method according to any one of claims 2 to 18, wherein the method comprising: additionally oxidizing the lignin component or acidic filtrate.

20. The method according to any one of claims 2 to 19, wherein the method comprises a pre-treatment step before the at least one acid treatment stage.

21. The method according to claim 1, wherein the method comprising:
   - forming a lignin component of lignin material by treating the lignin material by means of an acid composition in at least one acid treatment stage; and
   - the lignin component is washed and neutralized by a pH-buffer during a filtration after the acid treatment, and pH in pH-buffer is between 4 - 10.

22. The method according to claim 21, wherein the at least one acid treatment stage is selected from a group consisting of acid washing, acid hydrolysis and their combinations.

23. The method according to claim 21 or 22, wherein the acid composition includes $\text{H}_2\text{SO}_4$. 
24. The method according to any one of claims 21 to 23, wherein the acid composition includes acidi-
ifying chemical.

25. The method according to any one of claims 21 to 24, wherein pH in pH-buffer is between 5 - 9.

26. The method according to any one of claims 21 to 25, wherein pH in pH-buffer is between 6 - 8.

27. The method according to any one of claims 21 to 26, wherein the pH-buffer includes buffer agent
selected from a group consisting of citrate, acetate, carbonate and their combinations.

28. The method according to any one of claims 21 to 27, wherein the method comprising: optimizing
process conditions in the acid treatment stage so that high temperature, long retention time and low pH level
are used during the acid treatment.

29. The method according to any one of claims 21 to 28, wherein the retention time which is over 6
hour is used during the acid treatment.

30. The method according to any one of claims 21 to 29, wherein the retention time which is over 10
hour is used during the acid treatment.

31. The method according to any one of claims 21 to 30, wherein the temperature which is over 70 °C
is used during the acid treatment.

32. The method according to any one of claims 21 to 31, wherein the pH level which is between 0.5 -
4 is used during the acid treatment.

33. A filtration device for filtrating a lignin component formed from lignin material by an ac-
id treatment in at least one acid treatment stage, wherein the filtration device (10) comprises a lignin
feeding equipment for feeding the lignin component (7) formed at an acid treatment stage into the filtration
device, a filtrating step for forming a cake of the lignin component, a washing step for washing the cake
and a pH-buffer feeding equipment (9) for feeding the
pH-buffer (8) into the washing step and for washing and neutralizing the lignin component by the pH-buffer.

34. The filtration device according to claim 33, wherein the filtration device (10) comprises a mixing device (11) in order to form the pH-buffer.

35. The filtration device according to claim 33 or 34, wherein the filtration device (10) comprises a controlling means to determine pH of the pH-buffer and/or adjust pH of the pH-buffer between 4 to 10.

36. The method according to claim 1, wherein the method comprising:
- forming a lignin component of lignin material by treating the lignin material in an acid treatment stage by means of an acid composition; and
- optimizing process conditions in the acid treatment stage so that high temperature over 70 °C, long retention time over 6 hours and pH level between 4.5 - 7 are used during the acid treatment.

37. The method according to claim 36, wherein the acid treatment stage is acid washing.

38. The method according to claim 36 or 37, wherein the acid composition includes H₂SO₄.

39. The method according to any one of claims 36 to 38, wherein the acid composition includes acidifying chemical containing salt.

40. The method according to any one of claims 36 to 39, wherein the acid composition includes sodium sesquisulphate.

41. The method according to any one of claims 36 to 40, wherein the pH level is between 5 and 6.

42. The method according to any one of claims 36 to 41, wherein the retention time is over 10 hours.

43. The method according to any one of claims 36 to 42, wherein the temperature is over 80 °C.
44. The method according to any one of claims 36 to 43, wherein the method comprising: filtrating the lignin component after the acid treatment stage.

45. The method according to any one of claims 36 to 44, wherein the lignin component is filtrated by pressure filtration or vacuum filtration.

46. The method according to any one of claims 36 to 45, wherein the pH level is re-adjusted just before the filtration.

47. The method according to any one of claims 36 to 46, wherein temperature is over 50 °C and pH is between 5 to 7 during the filtration.

48. The method according to any one of claims 1 to 47, wherein the method comprising: precipitating the lignin material before the acid treatment stage.

49. The method according to any one of claims 1 to 48, wherein the lignin material includes material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material by a solution including suitable chemicals and their combinations.

50. The method according to any one of claims 1 to 49, wherein the lignin material includes flash precipitated lignin.

51. A lignin component which is formed from lignin material by an acid treatment, wherein the lignin component has specific surface area between 0.1 - 1.0 m²/g.

52. The lignin component according to claim 51, wherein the lignin component which is dried and grinded has bulk density between 200 - 800 g/cm³.

53. A lignin component formed of lignin material which has been treated in at least one acid treatment stage, wherein ash and/or carbohydrates in the lignin component are decreased by optimizing the
at least one acid treatment stage by means of a combination of process parameters comprising retention

time, temperature and pH level.

54. The lignin component according to claim 53, wherein the lignin component contains under 0.1 %
of ash and under 0.1 % of carbohydrates.

55. A lignin component which is formed from lignin material by an acid treatment, wherein a lignin

component is formed of lignin material so that the lignin material is treated by means of an acid compo-
sition in at least one acid treatment stage; and the lignin component is washed and neutralized by a pH-
buffer during a filtration after the acid treatment, and pH in pH-buffer is between 4 – 10.

56. A lignin component which is formed from lignin material by an acid treatment, wherein a lignin

cOMPONENT is formed of lignin material so that the lignin material is treated in an acid treatment stage

by means of an acid composition, and the acid treat-

ment stage is optimized by means of process conditions

so that high temperature over 70 °C, long retention
time over 6 hours and pH level between 4.5 – 7 are

used during the acid treatment.

57. A use of the lignin component according to any one of claims 51 to 56, wherein the lignin com-

ponent is used as component in manufacturing a final product selected from a group consisting of activated

carbon, carbon fiber, lignin composite, binder materi-
al, phenolic component, dispersion agent and their

combinations.

58. A product which includes the lignin component obtainable by the method of any one of claims 1
to 50.

59. The product according to claim 58, wherein the product is selected from a group consist-
ing of activated carbon, carbon fiber, lignin compo-
60. A method for making a lignin component from a lignin material by an acid treatment, the method comprising:
- forming a lignin component of lignin material by treating the lignin material in at least one acid treatment stage; and
- decreasing ash and/or carbohydrates in the lignin component by optimizing the at least one acid treatment stage by means of a combination of process parameters comprising retention time, temperature and pH level.

61. The method according to claim 60, wherein the at least one acid treatment stage is acid washing.

62. The method according to claim 60 or 61, wherein the at least one acid treatment stage is acid hydrolysis.

63. The method according to any one of claims 60 to 62, wherein the method comprising: treating the lignin material in two acid treatment stages in which the first stage is acid washing and the second stage is acid hydrolysis.

64. The method according to any one of claims 60 to 63, wherein the method comprising: treating the lignin material in the at least one acid treatment stage such that dry solids content of the lignin component is increased over 5 % as compared with standard lignin component.

65. The method according to any one of claims 60 to 64, wherein the method comprising: treating the lignin material in the at least one acid treatment stage such that carbohydrates content of the lignin component is under 0.2 %.

66. The method according to any one of claims 60 to 65, wherein the method comprising: precipitating
the lignin material before the at least one acid treatment stage.

67. The method according to any one of claims 60 to 66, wherein the lignin material comprises material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material by a solution including suitable chemicals and their combinations.

68. The method according to any one of claims 60 to 67, wherein the lignin material comprises flash precipitated lignin.

69. The method according to any one of claims 60 to 68, wherein the method comprising: treating the lignin material in the at least one acid treatment stage with H₂SO₄.

70. The method according to any one of claims 60 to 69, wherein the retention time is over 1 hour.

71. The method according to any one of claims 60 to 70, wherein the temperature is over 70 °C.

72. The method according to any one of claims 60 to 71, wherein the pH level is between 0.5 - 1.5.

73. The method according to any one of claims 60 to 72, wherein the pH level is between 0.5 - 4.0, the temperature is between 80 - 130 °C and the retention time is between 2 - 60 hours at the at least one acid treatment stage.

74. The method according to any one of claims 60 to 73, wherein the method comprising: filtrating the lignin component after each of the at least one acid treatment stages.

75. The method according to any one of claims 74, wherein the method comprising: filtrating the lignin component by pressure filtration or vacuum filtration.
76. The method according to any one of claims 60 to 75, wherein the method comprising: adjusting the pH level just before the filtrating.

77. The method according to any one of claims 60 to 76, wherein the temperature is over 50 °C and the pH level is between 2 to 4 during the filtration.

78. The method according to any one of claims 60 to 77, wherein the method comprising: treating the lignin material in the at least one acid treatment stage; and optimizing the at least one acid treatment stage by means of process parameters selected from retention time, temperature, pH level, mixing, oxidizing and their combinations.

79. The method according to any one of claims 60 to 78, wherein the method comprising: adjusting proportion of lignin dissolved during the at least one acid treatment stage by means of process parameters selected from retention time, temperature, pH level, mixing efficiency, mixer type, oxidation and their combinations.

80. The method according to any one of claims 60 to 79, wherein the method comprising: additionally oxidizing the lignin component or acidic filtrate.

81. The method according to any one of claims 60 to 80, wherein the method comprises a pre-treatment step before the at least one acid treatment stage.

82. A lignin component formed of lignin material which has been treated in at least one acid treatment stage, wherein - ash and/or carbohydrates in the lignin component are decreased by optimizing the at least one acid treatment stage by means of a combination of process parameters comprising retention time, temperature and pH level.

83. The lignin component according to claim 82, wherein the lignin component contains under 0.1 % of ash and under 0.1 % of carbohydrates.
84. A use of the lignin component obtainable by the method of any one of claims 60 - 81, as component in manufacturing a final product selected from activated carbon, carbon fiber, lignin composite, binder material, phenolic component, dispersion agent and their combinations.

85. A product comprising the lignin component obtainable by the method of any one of claims 60 to 81.

86. The product according to claim 85, wherein the product is selected from activated carbon, carbon fiber, lignin composite, such as lignin-plastic composite and lignin-fiber composite, binder material, phenolic component, dispersion agent and their combinations.

87. A method for making a lignin component from a lignin material by an acid treatment, the method comprising:
- forming a lignin component of lignin material by treating the lignin material in an acid treatment stage by means of an acid composition; and
- optimizing process conditions in the acid treatment stage so that high temperature over 70 °C, long retention time over 6 hours and pH level between 4.5 - 7 are used during the acid treatment.

88. The method according to claim 87, wherein the acid treatment stage is acid washing.

89. The method according to claim 87 or 88, wherein the acid composition includes H₂SO₄.

90. The method according to any one of claims 87 to 89, wherein the acid composition includes acidifying chemical containing salt.

91. The method according to any one of claims 87 to 90, wherein the acid composition includes sodium sesquisulphate.

92. The method according to any one of claims 87 to 91, wherein the pH level is between 5 and 6.
93. The method according to any one of claims 87 to 92, wherein the retention time is over 10 hours.

94. The method according to any one of claims 87 to 93, wherein the temperature is over 80 °C.

95. The method according to any one of claims 87 to 94, wherein the lignin material is precipitated before the acid treatment stage.

96. The method according to any one of claims 87 to 95, wherein the lignin material includes material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material by a solution including suitable chemicals and their combinations.

97. The method according to any one of claims 87 to 96, wherein the lignin material includes flash precipitated lignin.

98. The method according to any one of claims 87 to 97, wherein the method comprising: filtrating the lignin component after the acid treatment stage.

99. The method according to any one of claims 87 to 98, wherein the lignin component is filtrated by pressure filtration or vacuum filtration.

100. The method according to any one of claims 87 to 99, wherein the pH level is re-adjusted just before the filtration.

101. The method according to any one of claims 87 to 100, wherein temperature is over 50 °C and pH is between 5 to 7 during the filtration.

102. A lignin component which is formed from a lignin material by an acid treatment, wherein
- a lignin component is formed of lignin material so that the lignin material is treated in an acid treatment stage by means of an acid composition; and
- the acid treatment stage is optimized by means of process conditions so that high temperature over 70 °C, long retention time over 6 hours and pH level between 4.5 - 7 are used during the acid treatment.

103. A use of the lignin component obtainable by the method of any one of claims 87 to 101, wherein the lignin component is used as component in manufacturing a final product selected from a group consisting of activated carbon, carbon fibre, binder material, phenol, dispersion agent and their combinations.

104. A product which includes the lignin component obtainable by the method of any one of claims 87 to 101.

105. The product according to claim 104, wherein the product is selected from the group consisting of: activated carbon, carbon fiber, lignin composite, such as lignin-plastic composite and lignin-fiber composite, binder material, phenolic component, dispersion agent and their combinations.

106. A method for making a lignin component from lignin material by an acid treatment, the method comprising:

- forming a lignin component of lignin material by treating the lignin material by means of an acid composition in at least one acid treatment stage; and
- the lignin component is washed and neutralized by a pH-buffer during a filtration after the acid treatment, and pH in pH-buffer is between 4 - 10.

107. The method according to claim 106, wherein the at least one acid treatment stage is selected from a group consisting of acid washing, acid hydrolysis and their combinations.

108. The method according to claim 106 or 107, wherein the acid composition includes H₂SO₄.
109. The method according to any one of claims 106 to 108, wherein the acid composition includes acidifying chemical.

110. The method according to any one of claims 106 to 109, wherein pH in pH-buffer is between 5 - 9.

111. The method according to any one of claims 106 to 110, wherein pH in pH-buffer is between 6 - 8.

112. The method according to any one of claims 106 to 111, wherein the pH-buffer includes buffer agent selected from a group consisting of citrate, acetate, carbonate and their combinations.

113. The method according to any one of claims 106 to 112, wherein the method comprising: optimizing process conditions in the acid treatment stage so that high temperature, long retention time and low pH level are used during the acid treatment.

114. The method according to any one of claims 106 to 113, wherein the retention time which is over 6 hour is used during the acid treatment.

115. The method according to any one of claims 106 to 114, wherein the retention time which is over 10 hour is used during the acid treatment.

116. The method according to any one of claims 106 to 115, wherein the temperature which is over 70 °C is used during the acid treatment.

117. The method according to any one of claims 106 to 116, wherein the pH level which is between 0.5 - 4 is used during the acid treatment.

118. The method according to any one of claims 106 to 117, wherein the lignin material includes material which is selected from a group consisting of lignin from alkaline pulping process, kraft lignin, lignin from soda process, lignin coming from a process in which lignin is separated the raw material
by a solution including suitable chemicals and their combinations.

119. The method according to any one of claims 106 to 118, wherein the lignin material includes flash precipitated lignin.

120. A filtration device for filtrating a lignin component formed from lignin material by an acid treatment in at least one acid treatment stage, wherein the filtration device (10) comprises a lignin feeding equipment for feeding the lignin component (7) formed at an acid treatment stage into the filtration device, a filtrating step for forming a cake of the lignin component, a washing step for washing the cake and a pH-buffer feeding equipment (9) for feeding the pH-buffer (8) into the washing step and for washing and neutralizing the lignin component by the pH-buffer.

121. The filtration device according to claim 120, wherein the filtration device (10) comprises a mixing device (11) in order to form the pH-buffer.

122. The filtration device according to claim 120 or 121, wherein the filtration device (10) comprises a controlling means to determine pH of the pH-buffer and/or adjust pH of the pH-buffer between 4 to 10.

123. A lignin component which is formed from lignin material by an acid treatment, wherein the lignin component has specific surface area between 0.1 - 1.0 m²/g.

124. The lignin component according to claim 123, wherein the lignin component which is dried and ground has bulk density between 200 - 800 g/cm³.

125. A lignin component which is formed from lignin material by an acid treatment, wherein

- a lignin component is formed of lignin material so that the lignin material is treated by means
of an acid composition in at least one acid treatment stage; and
- the lignin component is washed and neutralized by a pH-buffer during a filtration after the acid treatment, and pH in pH-buffer is between 4 - 10.

126. A use of the lignin component obtainable by the method of any one of claims 106 to 119, wherein the lignin component is used as component in manufacturing a final product selected from a group consisting of activated carbon, carbon fiber, lignin composite, binder material, phenolic component, dispersion agent and their combinations.

127. A product which includes the lignin component obtainable by the method of any one of claims 106 to 119.

128. The product according to claim 127, wherein the product is selected from a group consisting of activated carbon, carbon fiber, lignin composite, binder material, phenolic component, dispersion agent and their combinations.
