**METHOD FOR EXPRESSION OF SMALL ANTIVIRAL
RNA MOLECULES WITHIN A CELL**

Abstract

In ones aspect, the invention provides methods and compositions for the expression of small RNA molecules within a cell using a retroviral vector. The methods can be used to express double stranded RNA complexes. Small interfering RNA (siRNA) can be expressed using the methods of the invention within a cell, that interfere with a viral life cycle by down regulating either the viral genome, a viral genome transcript, or viral replication in a host cell. In another aspect, the invention provides methods for treating patients suffering from infection, particularly infection with HIV.

METHOD FOR EXPRESSION OF SMALL ANTIVIRAL RNA MOLECULES WITHIN A CELL

Government Support

[0001] This invention was made with government support under Grant Number GM39458 awarded by the National Institutes of Health. The United States Government has certain rights in the invention.

Background of the Invention

Field of the Invention

[0002] The present invention relates generally to methods for altering gene expression in a cell or animal using viral constructs engineered to deliver an RNA molecule, and more specifically to deliver double-stranded RNA molecules that can be used to down-regulate or modulate gene expression. Particular aspects of the invention relate to down-regulating a pathogenic virus gene or a gene necessary for a pathogenic virus life cycle through delivery of a viral construct engineered to express an RNA molecule.

Description of the Related Art

[0003] RNA interference (RNAi) or silencing is a recently discovered phenomenon (A. Fire *et al.*, *Nature* **391**, 806 (1998); C.E. Rocheleau *et al.* *Cell* **90**, 707 (1997)). Small interfering RNAs ("siRNAs") are double-stranded RNA molecules that inhibit the expression of a gene with which they share homology. siRNAs have been used as a tool to down regulate the expression of specific genes in a variety of cultured cells as well as in invertebrate animals. A number of such approaches have been reviewed recently (P.D. Zamore *Science* **296**, 1265 (2002)); however, such approaches have limitations. For example, no technique prior to the invention described herein allows for the generation of transgenic mammals having a specific gene down regulated through RNA interference. Similarly, there is a need for more robust methods for the introduction of small RNA molecules with regulatory function. The invention provided herein addresses these and other limitations in the field of RNA mediated gene regulation. Likewise, there is a need for improved methods and compositions for the treatment of viruses and diseases associated with viral infection.

Summary of the Invention

[0004] The invention relates generally to methods to express within a cell an RNA molecule or molecules. These methods can be used with a wide variety of cell types. RNA molecules can be expressed within a cell for a variety of purposes. For example, RNA molecules can serve as markers within a cell, can be antisense oligonucleotides or ribozymes for regulating gene expression, and can serve to down regulate genes through RNA interference.

[0005] In one aspect, the methods of the invention relate to the treatment or prevention of infection through the expression of one or more RNA molecules that inhibit one or more aspects of the life cycle of a pathogen through RNA interference with a target nucleic acid, such as a viral genome, a viral transcript or a host cell gene that is necessary for viral replication.

[0006] According to another aspect of the invention, a method of expressing an RNA molecule is provided which includes transfecting a packaging cell line with a retroviral construct and recovering recombinant retrovirus from the packaging cell line. A host cell is then infected with the recombinant retrovirus.

[0007] The recombinant retrovirus construct preferably has a first RNA polymerase III promoter region, at least one RNA coding region, and at least one termination sequence. The RNA coding region preferably comprises a sequence that is at least about 90% identical to a target sequence within the target nucleic acid. Preferably the target nucleic acid is necessary for the life cycle of a pathogen, for example, part of a pathogenic virus RNA genome or genome transcript, or part of a target cell gene involved in the life cycle of a pathogenic virus.

[0008] In one embodiment, the methods of the invention are used to disrupt the life cycle of a pathogen. In a particular embodiment the methods are used to disrupt the life cycle of a virus having an RNA genome, for example a retrovirus, by targeting the RNA genome directly. In another embodiment a viral genome transcript is targeted, including transcripts of individual viral genes. The methods also can be used to down regulate a gene in a host cell, where the gene is involved in the viral life cycle, for example, a receptor or co-receptor necessary for viral entry into the host cell.

[0009] In one aspect of the invention, the RNA coding region encodes an siRNA, preferably a self-complementary "hairpin" RNA molecule having a sense region, an antisense region and a loop region. The loop region is generally between about 2 and about 15 nucleotides in length, and in a more preferred embodiment is about 6 to about 9 nucleotides in length. The double-stranded region of the hairpin molecule comprises a nucleotide sequence that is homologous to the target sequence. The sequence in the hairpin molecule is preferably at least about 90% identical to a target sequence, more preferably at least about 95% identical, even more preferably at least about 99% identical.

[0010] In another embodiment, the RNA coding region encodes a first RNA molecule, and the retroviral construct has a second RNA polymerase III promoter and a second RNA coding region operably linked to the second RNA polymerase III promoter. In such an embodiment, the second RNA coding region encodes an RNA molecule substantially complementary to the first RNA molecule. Upon expression of the first and second RNA coding regions, a double-stranded complex is formed within a cell.

[0011] In yet another embodiment, the retroviral construct can have a second RNA polymerase III promoter region operably linked to the RNA coding region, such that expression of the RNA coding region from the first RNA polymerase III promoter results in the synthesis of a first RNA molecule and expression of the RNA coding region from the second RNA polymerase III promoter results in synthesis of a second RNA molecule substantially complementary to the first RNA molecule. In one such embodiment, the RNA polymerase III promoters are separated from the RNA coding region by termination sequences.

[0012] In one embodiment of the invention, the target cell is an embryonic cell. An embryonic cell as used herein includes a single cell embryo, and embryo cells within an early-stage embryo. In another embodiment of the invention, the target cell is an embryogenic stem cell. When the target cell is an embryonic cell, the embryonic cell can be infected by injecting the recombinant retrovirus between the zona pellucida and the cell membrane of a mammalian embryonic cell. In another embodiment, the embryonic cell can be infected by removing the zona pellucida and incubating the cell in solution containing the recombinant retrovirus. In such an embodiment, the zona pellucida can be removed by enzymatic digestion. When the target cell is an embryonic cell or an embryogenic stem cell, the methods of the invention also include implanting the embryonic cell in a

pseudopregnant female to generate a transgenic animal. In such a fashion, a transgenic animal can be generated that is resistant to a particular pathogen, such as a virus.

[0013] The methods of the invention can also be used with a variety of primary, ex vivo normal or diseased cells or cells adapted in various tissue culture conditions. The cells are preferably obtained from human, mouse or other vertebrates. The cells may include, without limitation, hematopoietic stem or precursor cells, central nerve system cells, cells with regenerative capacities for a variety of other tissues and organs, dendritic cells and other developing and mature myeloid and lymphoid cells, and cancer cells derived from different cell lineages.

[0014] In another aspect the invention provides retroviral constructs for the expression of an RNA molecule or molecules within a cell. The constructs preferably comprise an RNA polymerase III (pol III) promoter. In one embodiment the retroviral constructs have an RNA coding region operably linked to the RNA polymerase III promoter. The RNA coding region can be immediately followed by a pol III terminator sequence, which directs termination of RNA synthesis by pol III. The pol III terminator sequences generally have 4 or more consecutive thymidine ("T") residues. In a preferred embodiment, a cluster of 5 consecutive Ts is used as the terminator by which pol III transcription is stopped at the second or third T of the DNA template, and thus only 2 to 3 uridine ("U") residues are added to the 3' end of the coding sequence. A variety of pol III promoters can be used with the invention, including for example, the promoter fragments derived from H1 RNA genes or U6 snRNA genes of human or mouse origin or from any other species. In addition, pol III promoters can be modified/engineered to incorporate other desirable properties such as the ability to be induced by small chemical molecules, either ubiquitously or in a tissue-specific manner. For example, in one embodiment the promoter may be activated by tetracycline. In another embodiment the promoter may be activated by IPTG (lacI system).

[0015] The retroviral construct can be based on a number of retroviral vectors. In a preferred embodiment, the retroviral construct has the R and U5 sequences from a 5' lentiviral long terminal repeat (LTR) and a self-inactivating lentiviral 3' LTR. In another embodiment, the retroviral vector is derived from the murine stem cell virus (MSCV). In yet another embodiment, the retroviral construct is a hybrid of a lentiviral and a MSCV construct.

[0016] In a further embodiment, the RNA coding region encodes a self-complementary RNA molecule having a sense region, an antisense region and a loop region. Such an RNA molecule, when expressed, preferably forms a "hairpin" structure. A loop region is generally between about 2 to 15 nucleotides in length. In a preferred embodiment, the loop region is from 6 to 9 nucleotides in length. In one such embodiment of the invention, the sense region and the antisense region are between about 15 and about 30 nucleotides in length. In one embodiment, the RNA coding region of this embodiment of invention is operably linked downstream to an RNA polymerase III promoter in such that the RNA coding sequence can be precisely expressed without any extra non-coding nucleotides present at 5' end (ie., the expressed sequence is identical to the target sequence at the 5' end). The synthesis of the RNA coding region is ended at the terminator site. In one preferred embodiment the terminator has five consecutive T residues.

[0017] In another aspect of the invention, the retroviral vector can contain multiple RNA coding regions. In one such embodiment, the RNA coding region encodes a first RNA molecule, and the retroviral construct has a second RNA polymerase III promoter and a second RNA coding region operably linked to the second RNA polymerase III promoter. In this embodiment, the second RNA molecule can be substantially complementary to the first RNA molecule, such that the first and the second RNA molecules can form a double-stranded structure when expressed. The double stranded region of the RNA complex is at least about 90% identical to a target region of either a viral genome, a viral genome transcript or a target cell RNA encoding a protein necessary for the pathogenic virus life cycle. The methods of invention also include multiple RNA coding regions that encode hairpin-like self-complementary RNA molecules or other non-hairpin molecules.

[0018] In yet another embodiment of the invention, the retroviral construct has a second RNA polymerase III promoter operably linked to the same RNA coding region in the opposite direction, such that expression of the RNA coding region from the first RNA polymerase III promoter results in a synthesis of a first RNA molecule as the sense strand and expression of the RNA coding region from the second RNA polymerase III promoter results in synthesis of a second RNA molecule as antisense strand with substantial complementarity to the first RNA molecule. In such an embodiment, both RNA molecules can contain a 3' overhang of residues encoded by the termination sequence. In one

embodiment, both RNA polymerase III promoters are separated from the RNA coding region by termination sequences. Preferably the termination sequences comprise five consecutive T residues.

[0019] According to another aspect of the invention, the 5' LTR sequences can be derived from HIV. The retroviral construct can also have a woodchuck hepatitis virus enhancer element sequence and/or a tRNA amber suppressor sequence.

[0020] In one embodiment of the invention, the self-inactivating 3' LTR can be a U3 element with a deletion of its enhancer sequence. In yet another embodiment, the self-inactivating 3' LTR is a modified HIV 3' LTR.

[0021] The recombinant retroviral construct can be pseudotyped, for example with the vesicular stomatitis virus envelope glycoprotein.

[0022] According to another aspect of the invention, the viral construct also can encode a gene of interest. The gene of interest can be linked to a Polymerase II promoter. A variety of Polymerase II promoters can be used with the invention, including for example, the CMV promoter. The RNA Polymerase II promoter that is chosen can be a ubiquitous promoter, capable of driving expression in most tissues, for example, the human Ubiquitin-C promoter, CMV β -actin promoter and PGK promoter. The RNA Polymerase II promoter also can be a tissue-specific promoter. Such a construct also can contain, for example, an enhancer sequence operably linked with the Polymerase II promoter.

[0023] In one embodiment, the gene of interest is a marker or reporter gene that can be used to verify that the vector was successfully transfected or transduced and its sequences expressed. In one such embodiment, the gene of interest is a fluorescent reporter gene, for example, the Green Fluorescent Protein. In yet another embodiment, the gene of interest is a drug resistant gene which can be used to select the cells that are successfully transduced. For example, the drug resistant gene can be the zeocin resistant gene (zeo). The gene of interest also can be a hybrid of a drug resistant gene and a fluorescent reporter gene, such as a zeo/gfp fusion. In another aspect of the invention, the gene of interest encodes a protein factor that can regulate the transcription activity of inducible pol III promoters. In one of such embodiment, the gene of interest is tetR (repressor for tet operon) which regulates tetracycline responsive pol III promoters.

[0024] It is another aspect of the invention to provide methods for expressing an RNA molecule or molecules within a cell. In one embodiment a packaging cell line is

transfected with a retroviral construct of the invention, recombinant retroviral particles are recovered from the packaging cell line; and a target cell is infected with the recombinant retrovirus particles. According to such methods, the retroviral construct has the R and U5 sequences from a 5' lentiviral long terminal repeat (LTR), a self-inactivating lentiviral 3' LTR, a first RNA polymerase III promoter region and at least one RNA coding region. The retroviral construct also can have a termination sequence operably linked to the RNA coding region.

[0025] In a further aspect a method of treating a patient suffering from HIV infection is provided. In one embodiment, a CD34-positive target cell is isolated from the patient. The target cell is then infected with a recombinant retrovirus recovered from a packaging cell line transfected with a retroviral construct of the invention. Preferably, the recombinant retroviral construct comprises a first RNA polymerase III promoter region, at least one RNA coding region, and at least one termination sequence. In one embodiment the RNA coding region comprises a sequence that is at least about 90% identical to a target region of the HIV genome, an HIV genome transcript or a cellular gene that is involved in the HIV life cycle. The target region is preferably from about 18 to about 23 nucleotides in length.

[0026] In one embodiment the RNA coding region encodes a hairpin RNA molecule.

[0027] In a preferred embodiment, the RNA coding region is at least about 90% identical to a target region of the CCR5 gene or the CXCR4 gene.

Brief Description of the Drawings

[0028] Figure 1A shows a schematic diagram of a retroviral vector carrying an expression cassette for RNA expression, termed "RNA cassette" and a "Marker Gene" or gene of interest. The RNA expression cassette can be embedded at any permissible sites of the retroviral construct either as single copy or multiple tandem copies. In addition, although not indicated in the figure, more than one RNA expression cassette may be present in the retroviral construct. Figure 1B shows a similar construct in which the RNA expression cassettes flank a marker gene.

[0029] Figure 2 shows a schematic view of an RNA expression cassette having a RNA polymerase III promoter **100** linked to an siRNA region **110-130**, having a sense region **110**, a loop region **120**, and an antisense region **130**, and a terminator sequence **140**.

[0030] Figure 3 shows a schematic view of an RNA expression cassette having a RNA polymerase III promoter **100** linked to a first RNA coding region **110** and a first terminator sequence **140** and a second RNA polymerase III promoter **105** linked to a second RNA coding region **115** and a second terminator **145**.

[0031] Figure 4 shows a schematic view of an RNA expression cassette having a first RNA polymerase III promoter **100** linked to an RNA coding region **110** and a first terminator sequence **145**. The expression cassette has a second RNA polymerase III promoter **105** linked to the RNA coding region **115**, the same sequence as **110** in reverse, and a second terminator **140**.

[0032] Figure 5. Schematic illustration of a lacZ siRNA encoding lentiviral vector. 5'LTR: an HIV based lentiviral vector 5' LTR; F: an HIV Flap element; pol III: a human H1-RNA pol III promoter (-240 to -8); siRNA: a lacZ specific small hairpin RNA coding region and its structure and detailed sequence are illustrated below. UbiC: an internal human ubiquitinC promoter; GFP: a GFP marker gene driven by UbiC promoter. W: a woodchuck RNA regulatory element. 3'LTR: an HIV based self inactivating lentiviral 3' LTR.

[0033] Figure 6. A lacZ specific siRNA encoded by a lentiviral vector can efficiently inhibit the expression of lacZ reporter gene in virus transduced mammalian cells. MEF: mouse embryonic fibroblasts; HEK293: human embryonic kidney cells. Both of the test cell lines harbor lacZ and firefly luciferase reporter genes, and the expression levels of the reporter genes can be measured by chemiluminescent assays. Ctrl: the ratio of lacZ activity versus Luc activity of the uninfected parental cells, which was arbitrarily set to 1. Transduced: the specific inhibition of lacZ expression calculated as the reduction of lacZ to Luc ratio.

[0034] Figure 7. Transgenic animals that express a lacZ specific siRNA molecule encoded by a lentiviral vector can successfully suppress the expression of the ubiquitous lacZ reporter gene in a ROSA26^{+/-} background. ROSA1-6: the lacZ activities in the limb tissues of six E17.5 ROSA26^{+/-} embryos which served as positive controls. The difference in lacZ activity between individual ROSA26^{+/-} embryos may result from

variable protein extraction efficiency. TG1-4: the lacZ activities in the limb tissues of four E17.5 transgenic embryos expressing a lentiviral vector-encoded lacZ siRNA molecule in ROSA+/- background. WT1-6: lacZ activity in the limb tissues of six E17.5 C57Bl/6 wildtype embryos, included as the negative control. The background levels of endogenous beta-galactosidase activity are general below 1,000 LU/ug, thus the columns are not visible.

[0035] Figure 8 shows a schematic illustration of a Tet-inducible lacZ siRNA lentiviral vector. A Tet repressor gene (TetR; SEQ ID NO: 7) is under the control of human UbiquitinC promoter and its expression can be monitored by the downstream GFP marker coupled by IRES element (internal ribosomal entry site). The anti-lacZ siRNA cassette is driven by a Tet-inducible pol III promoter derived from human U6-promoter (-328 to +1) containing a single TetR binding site (TetO1) between the PSE and TATA box (SEQ ID NO: 6). In the absence of tetracycline, TetR binds to the promoter and its expression is repressed. Upon the addition of tetracycline, TetR is moved from the promoter and transcription starts.

[0036] Figure 9 shows the results of an experiment that demonstrated that a Tet-inducible siRNA expression cassette can regulate gene expression in response to Doxycycline treatment. lacZ and luciferase double expressing HEK293 cells (293Z+Luc) were transduced with a lentiviral vector carrying a Tet-inducible lacZ-siRNA cassette and a Tet repressor under the control of a UbiquitinC promoter (Figure 8). The transduced cells were treated with 10 ug/ml Doxycycline (Plus Dox) for 48hr or without the Doxycycline treatment as a control (No Dox). LacZ and luciferase activities were measured as described in the previous figures. The relative suppression activity is calculated as the ratio of lacZ versus luciferase and No Dox control was arbitrarily set to 1.

[0037] Figure 10 shows a schematic illustration of an anti-human CCR5 siRNA encoding lentiviral vector. 5'LTR: an HIV based lentiviral vector 5' LTR; F: an HIV Flap element; a human U6-RNA pol III promoter (-328 to +1); siRNA: a human CCR5 specific short hairpin cassette and its structure and detailed sequence are illustrated below. UbiC: an internal human ubiquitinC promoter; GFP: a GFP marker gene driven by UbiC promoter. W: a woodchuck RNA regulatory element. 3'LTR: an HIV based self-inactivating lentiviral 3' LTR.

[0038] Figure 11. A anti-human CCR5 specific siRNA encoded by a lentiviral vector can efficiently suppress the expression of CCR5 in transduced human cells. Cell

surface expression of CCR5 on transduced or untransduced MAGI-CCR5 (Deng, et al., Nature, 381, 661 (1996)) was measured by flow cytometric analysis (FACS) and the relative expression levels were calculated by mean fluorescence intensity. A non-specific siRNA was also included as a control.

[0039] Figure 12. Schematic illustration of an anti-HIV-1 siRNA encoding lentiviral vector. 5'LTR: an HIV based lentiviral vector 5' LTR; F: an HIV Flap element; a human H1-RNA pol III promoter (-240 to-9); siRNA: a HIV-1 Rev gene specific short hairpin cassette and its structure and detailed sequence are illustrated below. UbiC: an internal human ubiquitinC promoter; GFP: a GFP marker gene driven by UbiC promoter. W: a woodchuck RNA regulatory element. 3'LTR: an HIV based self inactivating lentiviral 3' LTR.

[0040] Figure 13 demonstrates that an anti-HIV-1 Rev gene specific siRNA encoded by a lentiviral vector can efficiently suppress the expression of HIV transcription in human cells. The transcription activity of HIV-1 virus is measured a firefly luciferase reporter gene inserted at the env/nef region (Li, et al J Virol., 65, 3973 (1991)). The luciferase activity of the untransduced parental cells was arbitrarily set to 1 and the relative HIV transcription levels of the transduced cells were calculated accordingly. A non-specific siRNA containing vector was included as a control.

[0041] Figure 14 shows a schematic diagram of a bivalent retroviral vector carrying both anti-HIV Rev and anti-human CCR siRNA expression cassettes. Symbols are the same as depicted in the previous figures.

Detailed Description of the Preferred Embodiment

[0042] The inventors have identified a method for introducing a transgene of interest into a cell or animal. This technique is described in copending U.S. provisional patent application 60/322,031 filed on 9/13/2001 and copending U.S. provisional patent application 60/347,782 filed on 1/9/2002.

[0043] Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Any methods, devices and materials similar or equivalent to those described herein can be used in the practice of this invention.

[0044] By “transgene” is meant any nucleotide sequence, particularly a DNA sequence, that is integrated into one or more chromosomes of a host cell by human intervention, such as by the methods of the present invention. In one embodiment, a transgene is an “RNA coding region.” In another embodiment the transgene comprises a “gene of interest.” In other embodiments the transgene can be a nucleotide sequence, preferably a DNA sequence, that is used to mark the chromosome where it has integrated. In this situation, the transgene does not have to comprise a gene that encodes a protein that can be expressed.

[0045] A “gene of interest” is a nucleic acid sequence that encodes a protein or other molecule that is desirable for integration in a host cell. In one embodiment, the gene of interest encodes a protein or other molecule the expression of which is desired in the host cell. In this embodiment, the gene of interest is generally operatively linked to other sequences that are useful for obtaining the desired expression of the gene of interest, such as transcriptional regulatory sequences.

[0046] A “functional relationship” and “operably linked” mean, without limitation, that the gene is in the correct location and orientation with respect to the promoter and/or enhancer that expression of the gene will be affected when the promoter and/or enhancer is contacted with the appropriate molecules.

[0047] An “RNA coding region” is a nucleic acid that can serve as a template for the synthesis of an RNA molecule, such as an siRNA. Preferably, the RNA coding region is a DNA sequence.

[0048] A “small interfering RNA” or “siRNA” is a double-stranded RNA molecule that is capable of inhibiting the expression of a gene with which it shares homology. The region of the gene or other nucleotide sequence over which there is homology is known as the “target region.” In one embodiment the siRNA may be a “hairpin” or stem-loop RNA molecule, comprising a sense region, a loop region and an antisense region complementary to the sense region. In other embodiments the siRNA comprises two distinct RNA molecules that are non-covalently associated to form a duplex.

[0049] The term “animal” is used in its broadest sense and refers to all animals including mammals, birds, fish, reptiles and amphibians.

[0050] The term “mammal” refers to all members of the class Mammalia and includes any animal classified as a mammal, including humans, domestic and farm animals,

and zoo, sports or pet animals, such as mouse, rabbit, pig, sheep, goat, cattle and higher primates.

[0051] "Target cell" or "host cell" means a cell that is to be transformed using the methods and compositions of the invention.

[0052] The term "pathogenic virus" is used herein to indicate a virus capable of infecting an animal.

[0053] "Retroviruses" are viruses having an RNA genome.

[0054] "Lentivirus" refers to a genus of retroviruses that are capable of infecting dividing and non-dividing cells. Several examples of lentiviruses include HIV (human immunodeficiency virus: including HIV type 1, and HIV type 2), the etiologic agent of the human acquired immunodeficiency syndrome (AIDS); visna-maedi, which causes encephalitis (visna) or pneumonia (maedi) in sheep, the caprine arthritis-encephalitis virus, which causes immune deficiency, arthritis, and encephalopathy in goats; equine infectious anemia virus, which causes autoimmune hemolytic anemia, and encephalopathy in horses; feline immunodeficiency virus (FIV), which causes immune deficiency in cats; bovine immune deficiency virus (BIV), which causes lymphadenopathy, lymphocytosis, and possibly central nervous system infection in cattle; and simian immunodeficiency virus (SIV), which cause immune deficiency and encephalopathy in sub-human primates.

[0055] A "hybrid virus" as used herein refers to a virus having components from one or more other viral vectors, including element from non-retroviral vectors, for example, adenoviral-retroviral hybrids. As used herein hybrid vectors having a retroviral component are to be considered within the scope of the retroviruses.

[0056] A lentiviral genome is generally organized into a 5' long terminal repeat (LTR), the gag gene, the pol gene, the env gene, the accessory genes (nef, vif, vpr, vpu) and a 3' LTR. The viral LTR is divided into three regions called U3, R and U5. The U3 region contains the enhancer and promoter elements. The U5 region contains the polyadenylation signals. The R (repeat) region separates the U3 and U5 regions and transcribed sequences of the R region appear at both the 5' and 3' ends of the viral RNA. See, for example, "RNA Viruses: A Practical Approach" (Alan J. Cant, Ed., Oxford University Press, (2000)), O Narayan and Clements J. Gen. Virology 70:1617-1639 (1989), Fields et al. Fundamental Virology Raven Press. (1990), Miyoshi H, Blomer U, Takahashi M, Gage FH, Verma IM. *J Virol.* 72(10):8150-7 (1998), and U.S. Patent No. 6,013,516.

[0057] Lentiviral vectors are known in the art, including several that have been used to transfect hematopoietic stem cells. Such vectors can be found, for example, in the following publications: Evans JT et al. *Hum Gene Ther* 1999;10:1479-1489; Case SS, Price MA, Jordan CT et al. *Proc Natl Acad Sci USA* 1999;96:2988-2993; Uchida N, Sutton RE, Frieria AM et al. *Proc Natl Acad Sci USA* 1998;95:11939-11944; Miyoshi H, Smith KA, Mosier DE et al. *Science* 1999;283:682-686; Sutton RE, Wu HT, Rigg R et al. Human immunodeficiency virus type 1 vectors efficiently transduce human hematopoietic stem cells. *J Virol* 1998;72:5781-5788.

[0058] "Virion," "viral particle" and "retroviral particle" are used herein to refer to a single virus comprising an RNA genome, *pol* gene derived proteins, *gag* gene derived proteins and a lipid bilayer displaying an envelope (glyco)protein. The RNA genome is usually a recombinant RNA genome and thus may contain an RNA sequence that is exogenous to the native viral genome. The RNA genome may also comprise a defective endogenous viral sequence.

[0059] A "pseudotyped" retrovirus is a retroviral particle having an envelope protein that is from a virus other than the virus from which the RNA genome is derived. The envelope protein may be from a different retrovirus or from a non-retroviral virus. A preferred envelope protein is the vesicular stomatitis virus G (VSV G) protein. However, to eliminate the possibility of human infection, viruses can alternatively be pseudotyped with ecotropic envelope protein that limit infection to a specific species, such as mice or birds. For example, in one embodiment, a mutant ecotropic envelope protein is used, such as the ecotropic envelope protein 4.17 (Powell et al. *Nature Biotechnology* 18(12):1279-1282 (2000)).

[0060] The term "provirus" is used to refer to a duplex DNA sequence present in a eukaryotic chromosome that corresponds to the genome of an RNA retrovirus. The provirus may be transmitted from one cell generation to the next without causing lysis or destruction of the host cell.

[0061] A "self-inactivating 3' LTR" is a 3' long terminal repeat (LTR) that contains a mutation, substitution or deletion that prevents the LTR sequences from driving expression of a downstream gene. A copy of the U3 region from the 3' LTR acts as a template for the generation of both LTR's in the integrated provirus. Thus, when the 3' LTR with an inactivating deletion or mutation integrates as the 5' LTR of the provirus, no

transcription from the 5' LTR is possible. This eliminates competition between the viral enhancer/promoter and any internal enhancer/promoter. Self-inactivating 3' LTRs are described, for example, in Zufferey et al. *J. Virol.* 72:9873-9880 (1998), Miyoshi et al. *J. Virol.* 72:8150-8157 and Iwakuma et al. *Virology* 261:120-132 (1999).

[0062] The term "RNA interference or silencing" is broadly defined to include all posttranscriptional and transcriptional mechanisms of RNA mediated inhibition of gene expression, such as those described in P.D. Zamore *Science* 296, 1265 (2002).

[0063] "Substantial complementarity" and "substantially complementary" as used herein indicate that two nucleic acids are at least 80% complementary, more preferably at least 90% complementary and most preferably at least 95% complementary over a region of more than about 15 nucleotides and more preferably more than about 19 nucleotides.

[0064] In one aspect of the invention, a recombinant retrovirus is used to deliver an RNA coding region of interest to a cell, preferably a mammalian cell. The cell may be a primary cell or a cultured cell. In one embodiment the cell is an oocyte or an embryonic cell, more preferably a one-cell embryo. In another embodiment the cell is a hematopoietic stem cell. The RNA coding region and any associated genetic elements are thus integrated into the genome of the host cell as a provirus. When the target cell is an embryo, the cell may then be allowed to develop into a transgenic animal by methods well known in the art.

[0065] The recombinant retrovirus used to deliver the RNA coding region is preferably a modified lentivirus, and thus is able to infect both dividing and non-dividing cells. The recombinant retrovirus preferably comprises a modified lentiviral genome that includes an RNA coding region. Further, the modified lentiviral genome preferably lacks endogenous genes for proteins required for viral replication, thus preventing undesired replication, such as replication in the target cells. The required proteins are preferably provided in *trans* in the packaging cell line during production of the recombinant retrovirus, as described below.

[0066] In another embodiment, the recombinant retrovirus used to deliver the RNA coding region is a modified Moloney virus, for example a Moloney Murine Leukemia Virus. In a further embodiment, the virus is a Murine Stem Cell Virus (Hawley, R. G., et al. (1996) *Proc. Natl. Acad. Sci. USA* 93:10297-10302; Keller, G., et al. (1998) *Blood* 92:877-887; Hawley, R. G., et al. (1994) *Gene Ther.* 1:136-138). The recombinant

retrovirus also can be a hybrid virus such as that described in Choi, JK; Hoanga, N; Vilardi, AM; Conrad, P; Emerson, SG; Gewirtz, AM. (2001) Hybrid HIV/MSCV LTR Enhances Transgene Expression of Lentiviral Vectors in Human CD34+ Hematopoietic Cells. *Stem Cells* **19**, No. 3, 236-246.

[0067] In one embodiment the transgene, preferably an RNA coding region, is incorporated into a viral construct that comprises an intact retroviral 5' LTR and a self-inactivating 3' LTR. The viral construct is preferably introduced into a packaging cell line that packages viral genomic RNA based on the viral construct into viral particles with the desired host specificity. Viral particles are collected and allowed to infect the host cell. Each of these aspects is described in detail below.

The Viral Construct

[0068] The viral construct is a nucleotide sequence that comprises sequences necessary for the production of recombinant viral particles in a packaging cell. In one embodiment the viral construct additionally comprises genetic elements that allow for the desired expression of a gene of interest in the host.

[0069] Generation of the viral construct can be accomplished using any suitable genetic engineering techniques well known in the art, including, without limitation, the standard techniques of PCR, oligonucleotide synthesis, restriction endonuclease digestion, ligation, transformation, plasmid purification, and DNA sequencing, for example as described in Sambrook et al. (*Molecular Cloning: A Laboratory Manual*. Cold Spring Harbor Laboratory Press, N.Y. (1989)), Coffin et al. (*Retroviruses*. Cold Spring Harbor Laboratory Press, N.Y. (1997)) and "RNA Viruses: A Practical Approach" (Alan J. Cann, Ed., Oxford University Press, (2000)).

[0070] The viral construct may incorporate sequences from the genome of any known organism. The sequences may be incorporated in their native form or may be modified in any way. For example, the sequences may comprise insertions, deletions or substitutions. In a preferred embodiment the viral construct comprises sequences from a lentivirus genome, such as the HIV genome or the SIV genome. In another preferred embodiment, the viral construct comprises sequences of a murine stem cell virus (MSCV).

[0071] The viral construct preferably comprises sequences from the 5' and 3' LTRs of a lentivirus, a moloney murine leukemia virus, a murine stem cell virus or hybrids

thereof. In one embodiment, the viral construct comprises the R and U5 sequences from the 5' LTR of a lentivirus and an inactivated or self-inactivating 3' LTR from a lentivirus. The LTR sequences may be LTR sequences from any lentivirus from any species. For example, they may be LTR sequences from HIV, SIV, FIV or BIV. Preferably the LTR sequences are HIV LTR sequences. The virus also can incorporate sequences from MMV or MSCV.

[0072] The viral construct preferably comprises an inactivated or self-inactivating 3' LTR. The 3' LTR may be made self-inactivating by any method known in the art. In one embodiment the U3 element of the 3' LTR contains a deletion of its enhancer sequence, preferably the TATA box, Sp1 and NF-kappa B sites. As a result of the self-inactivating 3' LTR, the provirus that is integrated into the host cell genome will comprise an inactivated 5' LTR.

[0073] Optionally, the U3 sequence from the lentiviral 5' LTR may be replaced with a promoter sequence in the viral construct. This may increase the titer of virus recovered from the packaging cell line. An enhancer sequence may also be included. Any enhancer/promoter combination that increases expression of the viral RNA genome in the packaging cell line may be used. In one such embodiment the CMV enhancer/promoter sequence is used (U.S. Patent No. 5,168,062; Karasuyama et al J. Exp. Med. 169:13 (1989).

[0074] The viral construct also comprises a transgene. The transgene, may be any nucleotide sequence, including sequences that serve as markers for the provirus. Preferably the transgene comprises one or more RNA coding regions and/or one or more genes of interest.

[0075] In the preferred embodiment the transgene comprises at least one RNA coding region. Preferably the RNA coding region is a DNA sequence that can serve as a template for the expression of a desired RNA molecule in the host cell. In one embodiment, the viral construct comprises two or more RNA coding regions.

[0076] The viral construct also preferably comprises at least one RNA Polymerase III promoter. The RNA Polymerase III promoter is operably linked to the RNA coding region and can also be linked to a termination sequence. In addition, more than one RNA Polymerase III promoter may be incorporated.

[0077] RNA polymerase III promoters are well known to one of skill in the art. A suitable range of RNA polymerase III promoters can be found, for example, in Paule and

White. *Nucleic Acids Research*, Vol 28, pp 1283-1298 (2000).

The definition of RNA polymerase III promoters also include any synthetic or engineered DNA fragment that can direct RNA polymerase III to transcribe its downstream RNA coding sequences. Further, the RNA polymerase III (Pol III) promoter or promoters used as part of the viral vector can be inducible. Any suitable inducible Pol III promoter can be used with the methods of the invention. Particularly suited Pol III promoters include the tetracycline responsive promoters provided in Ohkawa and Taira *Human Gene Therapy*, Vol. 11, pp 577-585 (2000) and in Meissner *et al. Nucleic Acids Research*, Vol. 29, pp 1672-1682 (2001).

[0078] In one embodiment the viral construct further comprises a gene that encodes a protein that is desirably expressed in one or more of the target cells, for example, a reporter or marker protein. Preferably the gene of interest is located between the 5' LTR and 3' LTR sequences. Further, the gene of interest is preferably in a functional relationship with other genetic elements, for example transcription regulatory sequences such as promoters and/or enhancers, to regulate expression of the gene of interest in a particular manner once the gene of interest is incorporated into the target cell genome. In certain embodiments, the useful transcriptional regulatory sequences are those that are highly regulated with respect to activity, both temporally and spatially.

[0079] Preferably the gene of interest is in a functional relationship with an internal Polymerase II promoter/enhancer regulatory sequences. An "internal" promoter/enhancer is one that is located between the 5' LTR and the 3' LTR sequences in the viral construct and is operably linked to the gene that is desirably expressed.

[0080] The Polymerase II promoter/enhancer may be any promoter, enhancer or promoter/enhancer combination known to increase expression of a gene with which it is in a functional relationship. A "functional relationship" and "operably linked" mean, without limitation, that the transgene or RNA coding region is in the correct location and orientation with respect to the promoter and/or enhancer that expression of the gene will be affected when the promoter and/or enhancer is contacted with the appropriate molecules.

[0081] In another embodiment, the gene of interest is a gene included for safety concerns to allow for the selective killing of the treated target cells within a heterogeneous population, for example within an animal, or more particularly within a human patient. In

one such embodiment, the gene of interest is a thymidine kinase gene (TK) the expression of which renders a target cell susceptible to the action of the drug gancyclovir.

[0082] In addition, more than one gene of interest may be placed in functional relationship with the internal promoter. For example a gene encoding a marker protein may be placed after the primary gene of interest to allow for identification of cells that are expressing the desired protein. In one embodiment a fluorescent marker protein, preferably green fluorescent protein (GFP), is incorporated into the construct along with the gene of interest. If a second reporter gene is included, an internal ribosomal entry site (IRES) sequence is also preferably included (U.S. Patent No. 4,937,190). The IRES sequence may facilitate the expression of the reporter gene.

[0083] The viral construct may also contain additional genetic elements. The types of elements that may be included in the construct are not limited in any way and will be chosen by the skilled practitioner to achieve a particular result. For example, a signal that facilitates nuclear entry of the viral genome in the target cell may be included. An example of such a signal is the HIV-1 flap signal.

[0084] Further, elements may be included that facilitate the characterization of the provirus integration site in the genome of the animal. For example, a tRNA amber suppressor sequence may be included in the construct.

[0085] In addition, the construct may contain one or more genetic elements designed to enhance expression of the gene of interest. For example, a woodchuck hepatitis virus responsive element (WRE) may be placed into the construct (Zufferey et al. *J. Virol.* 74:3668-3681 (1999); Deglon et al. *Hum. Gene Ther.* 11:179-190 (2000)).

[0086] A chicken β -globin insulator (Chung et al. *Proc. Natl. Acad. Sci. USA* 94:575-580 (1997)) may also be included in the viral construct. This element has been shown to reduce the chance of silencing the integrated provirus in a target cell due to methylation and heterochromatinization effects. In addition, the insulator may shield the internal enhancer, promoter and exogenous gene from positive or negative positional effects from surrounding DNA at the integration site on the chromosome.

[0087] Any additional genetic elements are preferably inserted 3' of the gene of interest or RNA coding region.

[0088] In a specific embodiment, the viral vector comprises: an RNA pol III promoter sequence; the R and U5 sequences from the HIV 5' LTR; the HIV-1 flap signal;

an internal enhancer; an internal promoter; a gene of interest; the woodchuck hepatitis virus responsive element; a tRNA amber suppressor sequence; a U3 element with a deletion of its enhancer sequence; the chicken β -globin insulator; and the R and U5 sequences of the 3' HIV LTR.

[0089] The viral construct is preferably cloned into a plasmid that may be transfected into a packaging cell line. The preferred plasmid preferably comprises sequences useful for replication of the plasmid in bacteria.

[0090] Schematic diagrams of exemplary retroviral constructs are shown in Figures 1A and 1B.

Production of Virus

[0091] Any method known in the art may be used to produce infectious retroviral particles whose genome comprises an RNA copy of the viral construct described above.

[0092] Preferably, the viral construct is introduced into a packaging cell line. The packaging cell line provides the viral proteins that are required *in trans* for the packaging of the viral genomic RNA into viral particles. The packaging cell line may be any cell line that is capable of expressing retroviral proteins. Preferred packaging cell lines include 293 (ATCC CCL X), HeLa (ATCC CCL 2), D17 (ATCC CCL 183), MDCK (ATCC CCL 34), BHK (ATCC CCL-10) and Cf2Th (ATCC CRL 1430). The most preferable cell line is the 293 cell line.

[0093] The packaging cell line may stably express the necessary viral proteins. Such a packaging cell line is described, for example, in U.S. Patent No. 6,218,181. Alternatively a packaging cell line may be transiently transfected with plasmids comprising nucleic acid that encodes the necessary viral proteins.

[0094] In one embodiment a packaging cell line that stably expresses the viral proteins required for packaging the RNA genome is transfected with a plasmid comprising the viral construct described above.

[0095] In another embodiment a packaging cell line that does not stably express the necessary viral proteins is co-transfected with two or more plasmids essentially as described in Yee et al. (*Methods Cell. Biol.* 43A, 99-112 (1994)). One of the plasmids comprises the viral construct comprising the RNA coding region. The other plasmid(s)

comprises nucleic acid encoding the proteins necessary to allow the cells to produce functional virus that is able to infect the desired host cell.

[0096] The packaging cell line may not express envelope gene products. In this case the packaging cell line will package the viral genome into particles that lack an envelope protein. As the envelope protein is responsible, in part, for the host range of the viral particles, the viruses are preferably pseudotyped. Thus the packaging cell line is preferably transfected with a plasmid comprising sequences encoding a membrane-associated protein that will permit entry of the virus into a host cell. One of skill in the art will be able to choose the appropriate pseudotype for the host cell that is to be used. For example, in one embodiment the viruses are pseudotyped with the vesicular stomatitis virus envelope glycoprotein (VSVg). In addition to conferring a specific host range this pseudotype may permit the virus to be concentrated to a very high titer. Viruses can alternatively be pseudotyped with ecotropic envelope proteins that limit infection to a specific species, such as mice or birds. For example, in another embodiment, a mutant ecotropic envelope protein is used, such as the ecotropic envelope protein 4.17 (Powell et al. *Nature Biotechnology* 18(12):1279-1282 (2000)).

[0097] In the preferred embodiment a packaging cell line that does not stably express viral proteins is transfected with the viral construct, a second vector comprising the HIV-1 packaging vector with the *env*, *nef*, 5'LTR, 3'LTR and *vpu* sequences deleted, and a third vector encoding an envelope glycoprotein. Preferably the third vector encodes the VSVg envelope glycoprotein.

[0098] In another embodiment of invention, RNA interference activity of the packaging cells is suppressed to improve the production of recombinant virus. This includes, without limitation, the use of cotransfection or stable transfection of constructs expressing siRNA molecules to inhibit Dicer, an RNase III family member of ribonuclease which is essential for RNA interference (Hammond et al. *Nat. Rev. Genet.* 2:110-119 (2001)).

[0099] The recombinant virus is then preferably purified from the packaging cells, titered and diluted to the desired concentration.

Delivery of the Virus

[0100] The virus may be delivered to the cell in any way that allows the virus to infect the cell. Preferably the virus is allowed to contact the cell membrane. A preferred method of delivering the virus to mammalian cells is through direct contact.

[0101] In one embodiment, the target cells are preferably contacted with the virus in culture plates. The virus may be suspended in media and added to the wells of a culture plate. The media containing the virus may be added prior to the plating of the cells or after the cells have been plated. Preferably cells are incubated in an appropriate amount of media to provide viability and to allow for suitable concentrations of virus in the media such that infection of the host cell occurs.

[0102] The cells are preferably incubated with the virus for a sufficient amount of time to allow the virus to infect the cells. Preferably the cells are incubated with virus for at least 1 hour, more preferably at least 5 hours and even more preferably at least 10 hours.

[0103] In any such embodiments, any concentration of virus that is sufficient to infect the cell may be used. When the target cell is to be cultured, the concentration of the viral particles is at least 1 pfu/ μ l, more preferably at least 10 pfu/ μ l, even more preferably at least 400 pfu/ μ l and even more preferably at least 1×10^4 pfu/ μ l.

[0104] Following infection with the virus, the cells can be introduced into an animal. The location of introduction of cultured cells will depend on the cell type used. For example, when the cells are hematopoietic cells, the cells can be introduced into the peripheral blood stream. The cells introduced into an animal are preferably cells derived from that animal, to avoid an adverse immune response. Cells also can be used that are derived from a donor animal having a similar immune makeup. Other cells also can be used, including those designed to avoid an immunogenic response.

[0105] In another embodiment, a suitable amount of virus is introduced into an animal directly, for example through injection into the body. In one such embodiment, the viral particles are injected into the animal's peripheral blood stream. Other injection locations also are suitable. Depending on the type of virus, introduction can be carried out through other means including for example, inhalation, or direct contact with epithelial tissues, for example those in the eye, mouth or skin.

[0106] The cells and animals incorporating introduced cells may be analyzed, for example for integration of the RNA coding region, the number of copies of the RNA coding region that integrated, and the location of the integration. Such analysis may be carried out at any time and may be carried out by any methods known in the art. Standard techniques are described, for example, in Hogan et al. (supra).

[0107] The methods of infecting cells disclosed above do not depend upon species-specific characteristics of the cells. As a result, they are readily extended to all mammalian species.

[0108] As discussed above, the modified retrovirus can be pseudotyped to confer upon it a broad host range. One of skill in the art would also be aware of appropriate internal promoters to achieve the desired expression of a gene of interest in a particular animal species. Thus, one of skill in the art will be able to modify the method of infecting cells derived from any species.

Down-regulating Gene Expression in a Target Cell

[0109] The methods described herein allow the expression of RNA molecules in cells, and are particularly suited to the expression of small RNA molecules, which can not be readily expressed from a Pol II promoter. According to a preferred embodiment of the invention, an RNA molecule is expressed within a cell in order to down-regulate the expression of a target gene. The ability to down-regulate a target gene has many therapeutic and research applications, including identifying the biological functions of particular genes. Using the techniques and compositions of the invention, it will be possible to knock-down (or down-regulate) the expression of a large number of genes, both in cell culture and in mammalian organisms. In particular, it is desirable to down-regulate genes in a target cell that are necessary for the life cycle of a pathogen, such as a pathogenic virus.

[0110] In preferred embodiments of the invention, an RNA expression cassette comprises a Pol III promoter and an RNA coding region. The RNA coding region preferably encodes an RNA molecule that is capable of down-regulating the expression of a particular gene or genes. The RNA molecule encoded can, for example, be complementary to the sequence of an RNA molecule encoding a gene to be down-regulated. In such an embodiment, the RNA molecule is designed to act through an antisense mechanism.

[0111] A more preferred embodiment involves the expression of a double-stranded RNA complex, or an RNA molecule having a stem-loop or a so-called "hairpin" structure. As used herein, the term "RNA duplex" refers to the double stranded regions of both the RNA complex and the double-stranded region of the hairpin or stem-loop structure. An RNA coding region can encode a single stranded RNA, two or more complementary single stranded RNAs or a hairpin forming RNA.

[0112] Double stranded RNA has been shown to inhibit gene expression of genes having a complementary sequence through a process termed RNA interference or suppression (see, for example, Hammond et al. *Nat. Rev. Genet.* 2:110-119 (2001)).

[0113] According to the invention, the RNA duplex or siRNA corresponding to a region of a gene to be down-regulated is expressed in the cell. The RNA duplex is substantially identical (typically at least about 80% identical, and more typically at least about 90% identical) in sequence to the sequence of the gene targeted for down regulation. siRNA duplexes are described, for example, in Bummelkamp et al. *Science* 296:550-553 (2002), Caplen et al. *Proc. Natl. Acad. Sci. USA* 98:9742-9747 (2001) and Paddison et al. *Genes & Devel.* 16:948-958 (2002).

[0114] The RNA duplex is generally at least about 15 nucleotides in length and is preferably about 15 to about 30 nucleotides in length. In some organisms, the RNA duplex can be significantly longer. In a more preferred embodiment, the RNA duplex is between about 19 and 22 nucleotides in length. The RNA duplex is preferably identical to the target nucleotide sequence over this region.

[0115] When the gene to be down regulated is in a family of highly conserved genes, the sequence of the duplex region can be chosen with the aid of sequence comparison to target only the desired gene. If there is sufficient identity among a family of homologous genes within an organism, a duplex region can be designed that would down regulate a plurality of genes simultaneously.

[0116] The duplex RNA can be expressed in a cell from a single retroviral construct. In the preferred embodiment, a single RNA coding region in the construct serves as a template for the expression of a self-complementary hairpin RNA, comprising a sense region, a loop region and an antisense region. This embodiment is illustrated in Figure 2, which shows a schematic view of an RNA expression cassette having an RNA Pol III promoter 100 operatively linked to an RNA coding region, having a sense region 110, a

loop region 120, an antisense region 130 and a terminator region 140. The sense 110 and antisense 130 regions are each preferably about 15 to about 30 nucleotides in length. The loop region 120 preferably is about 2 to about 15 nucleotides in length, more preferably from about 4 to about 9 nucleotides in length. Following expression the sense and antisense regions form a duplex.

[0117] In another embodiment, the retroviral construct comprises two RNA coding regions. The first coding region is a template for the expression of a first RNA and the second coding region is a template for the expression of a second RNA. Following expression, the first and second RNA's form a duplex. The retroviral construct preferably also comprises a first Pol III promoter operably linked to the first RNA coding region and a second Pol III promoter operably linked to the second RNA coding region. This embodiment is illustrated in Figure 3, which shows a schematic view of an RNA expression cassette having an RNA Polymerase III promoter 100 linked to a first RNA coding region 110 and a first terminator sequence 140 and a second RNA polymerase III promoter 105 linked to a second RNA coding region 115 and a second terminator 145.

[0118] In yet another embodiment of the invention, the retroviral construct comprises a first RNA Pol III promoter operably linked to a first RNA coding region, and a second RNA Pol III promoter operably linked to the same first RNA coding region in the opposite direction, such that expression of the RNA coding region from the first RNA Pol III promoter results in a synthesis of a first RNA molecule as the sense strand and expression of the RNA coding region from the second RNA Pol III promoter results in synthesis of a second RNA molecule as an antisense strand that is substantially complementary to the first RNA molecule. In one such embodiment, both RNA Polymerase III promoters are separated from the RNA coding region by termination sequences, preferably termination sequences having five consecutive T residues. Figure 4 shows a schematic view of an RNA expression cassette having a first RNA Polymerase III promoter 100 linked to an RNA coding region 110 and a first terminator sequence 145. The expression cassette has a second RNA polymerase III promoter 105 linked to the RNA coding region 115, the same sequence as 110 in reverse, and a second terminator 140.

[0119] In further embodiments an RNA duplex is expressed using two or more retroviral constructs. In one embodiment, a first retroviral construct is used that directs the expression of a first RNA and a second retroviral construct is used that directs expression

of a second RNA that is complementary to the first. Following expression the first and second RNAs form a duplex region. It is preferred, however, that the entire duplex region is introduced using retroviral particles derived from a single retroviral construct. As discussed above, several strategies for expressing a duplex RNA from a single viral construct are shown in Figures 2-4.

[0120] The RNA duplexes may be flanked by single stranded regions on one or both sides of the duplex. For example, in the case of the hairpin, the single stranded loop region would connect the duplex region at one end.

[0121] The RNA coding region is generally operatively linked to a terminator sequence. The pol III terminators preferably comprise of stretches of 4 or more thymidine ("T") residues. In a preferred embodiment, a cluster of 5 consecutive Ts is linked immediately downstream of the RNA coding region to serve as the terminator. In such a construct pol III transcription is terminated at the second or third T of the DNA template, and thus only 2 to 3 uridine ("U") residues are added to the 3' end of the coding sequence.

[0122] The sequence of the RNA coding region, and thus the sequence of the RNA duplex, preferably is chosen to be complementary to the sequence of a gene whose expression is to be downregulated in a cell or organism. The degree of down regulation achieved with a given RNA duplex sequence for a given target gene will vary by sequence. One of skill in the art will be able to readily identify an effective sequence. For example, in order to maximize the amount of suppression, a number of sequences can be tested in cell culture prior to treating a target cell or generating a transgenic animal. As an understanding of the sequence requirements for RNA interference is determined, the RNA duplex can be selected by one of skill in the art.

Inhibition of Viral Replication and/or Gene Expression in a Target Cell

[0123] According to one aspect of the invention, the target of the RNA duplex is a sequence that is necessary for the life cycle or replication of a virus, including for example, gene expression of the virus and the expression of a cellular receptor or co-receptor necessary for viral replication. In one embodiment of the invention, the virus to be inhibited is the human immunodeficiency virus (HIV).

[0124] The invention also includes methods of treating a patient having a viral infection. In one embodiment the method comprises administering to the patient an

effective amount of a recombinant retroviral particle (or particles) encoding at least one double stranded RNA having at least 90% homology and preferably identical to a region of at least about 15 to 25 nucleotides in a nucleotide that is important for normal viral replication. For example, the double stranded RNA may have homology to a nucleic acid in a viral genome; a viral gene transcript or in a gene for a patient's cellular receptor that is necessary for the life cycle of the virus.

[0125] In one embodiment, the patient to be treated is infected with the human immunodeficiency virus. A target cell is removed from a patient prior to treatment with the recombinant virus particle. In a preferred embodiment, the target cell is a CD34-positive hematopoietic stem cell. Such stem cells can be purified by one of skill in the art. Methods for such purification are known and taught for example in U.S. Patents: 4,965,204; 4,714,680; 5,061,620; 5,643,741; 5,677,136; 5,716,827; 5,750,397 and 5,759,793. One method for purifying such CD34-positive stem cells involves centrifugation of peripheral blood samples to separate mononuclear cells and granulocytes and sorting by fluorescence activated cell sorting (FACS). Sorted cells can be enriched for CD34+ cells through any of the above techniques. In a particular embodiment, the cells are enriched for CD34+ cells through a magnetic separation technology such as that available from Miltenyi Biotec and described in the following publications: Kögler et al. (1998) Bone Marrow Transplant. 21: 233-241; Pasino et al. (2000) Br. J. Haematol. 108: 793-800. The isolated CD34-positive stem cell is treated with a recombinant retroviral particle having an RNA coding region encoding a double stranded RNA directed against one or more targets within the viral genome and/or cellular targets that are necessary for the viral life cycle, including, for example, receptors or co-receptors necessary for entry of the pathogenic virus. The treated stem cells are then reintroduced into the patient.

[0126] The methods of the invention can be used to treat a variety of viral diseases, including, for example, human immunodeficiency virus (HIV-1 and HIV-2), hepatitis A, hepatitis B, hepatitis C.

[0127] It is also possible to treat a patient with an anti-viral recombinant retrovirus in order to confer immunity or increased resistance for the patient to a desired pathogen, such as a virus.

Cellular Targets

[0128] According to the invention, one of skill in the art can target a cellular component, either an RNA or an RNA encoding a cellular protein necessary for the pathogen life cycle, particularly a viral life cycle. In a preferred embodiment, the cellular target chosen will not be a protein or RNA that is necessary for normal cell growth and viability. Suitable proteins for disrupting the viral life cycle include, for example, cell surface receptors involved in viral entry, including both primary receptors and secondary receptors, and transcription factors involved in the transcription of a viral genome, proteins involved in integration into a host chromosome, and proteins involved in translational or other regulation of viral gene expression.

[0129] A number of cellular proteins are known to be receptors for viral entry into cells. Some such receptors are listed in an article by E. Baranowski, C.M. Ruiz-Jarabo, and E. Domingo, "Evolution of Cell Recognition by Viruses," *Science* **292**: 1102-1105.

Some cellular receptors that are involved in recognition by viruses are listed below: Adenoviruses: CAR, Integrins, MHC I, Heparan sulfate glycoaminoglycan, Sialic Acid; Cytomegalovirus: Heparan sulfate glycoaminoglycan; Coxsackieviruses: Integrins, ICAM-1, CAR, MHC I; Hepatitis A: murine-like class I integral membrane glycoprotein; Hepatitis C: CD81, Low density lipoprotein receptor; HIV (*Retroviridae*): CD4, CXCR4, Heparan sulfate glycoaminoglycan; HSV: Heparan sulfate glycoaminoglycan, PVR, HveB, HveC; Influenza Virus: Sialic acid; Measles: CD46, CD55; Poliovirus: PVR, HveB, HveC; Human papillomavirus: Integrins. One of skill in the art will recognize that the invention is not limited to use with receptors that are currently known. As new cellular receptors and coreceptors are discovered, the methods of the invention can be applied to such sequences.

Human Immunodeficiency Virus (HIV)

HIV viral targets:

[0130] In one embodiment of the invention, the retroviral construct has an RNA coding region that encodes a double stranded molecule having at least 90% homology to the HIV viral RNA genome, an expressed region of the HIV viral genome, for example, to any region of about 19-25 nucleotides in length of the 9-kb transcript of the integrated HIV virus, or any of the variously spliced mRNA transcripts of HIV (Schwartz, S; Felber, BK; Benko, DM; Fenya, EM; Pavlakis, GN. Cloning and functional analysis of multiply spliced

mRNA species of human immunodeficiency virus type 1. *J. Virol.* 1990; 64(6): 2519-29). Target regions within the HIV transcripts can be chosen to correspond to any of the viral genes, including, for example, HIV-1 LTR, *vif*, *nef*, and *rev*. In another embodiment, the RNA coding region encodes a double stranded region having at least 90% homology to a receptor or co-receptor of the HIV virus. For example, the primary receptor for HIV entry into T cells is CD4. In a preferred embodiment, the co-receptors CXC chemokine receptor 4 (CXCR4) and CC chemokine receptor 5 (CCR5) are down-regulated according to the methods of the invention. CXCR4 (Fedderspiel et al. *Genomics* 16:707-712 (1993)) is the major co-receptor for T cell trophic strains of HIV while CCR5 (Mummidi et al. *J. Biol. Chem.* 272:30662-30671 (1997)) is the major co-receptor for macrophage trophic strains of HIV. Other cellular targets against HIV include the RNA transcripts for proteins involved in the HIV life cycle, including cyclophilin, CRM-1, importin- β , HP68 (Zimmerman C, et al. Identification of a host protein essential for assembly of immature HIV-1 capsids. *Nature* 415 (6867): 88-92 (2002)) and other as yet unknown cellular factors.

[0131]

Examples

Example 1

[0133] According to this example, an siRNA lentiviral construct against lacZ gene was constructed by insertion of the siRNA expression cassette into the PacI site of HC-FUGW vector (Figure 5). HC-FUGW vector (SEQ ID NO: 3) contains a GFP marker gene driven by human Ubiquitin promoter for tracking transduction events. The vector also contains an HIV DNA Flap element to improve the virus titers, and WPRE for high level expression of viral genes. The siRNA expression cassette is composed of a pol III promoter and a small hairpin RNA coding region followed by a pol III terminator site. The pol III promoter is derived from -240 to -8 region of human H1-RNA promoter and is connected

to the downstream RNA coding region through a 7 base pair linker sequence to ensure that the transcription is precisely initiated at the first nucleotide of the RNA coding sequence. The small hairpin RNA coding region contains a 19 nt sequence corresponding to 1915-1933 region of the sense strand of lacZ gene coding sequence and the 19 nt perfect reverse complementary sequence separated by a 9 nt loop region. The terminator is comprised of 5 consecutive thymidine residues linked immediately downstream of the RNA coding sequence.

Example 2

[0134] This example demonstrates the transduction of cultured mammalian cells with a retroviral vector (Figure 6). The retroviral vector encoding a small hairpin RNA molecule described in Example 1, was used to transfect cultured mammalian cells that express lacZ, and caused a profound decrease in the expression of the test gene lacZ. The lacZ siRNA virus was produced by cotransfection of the retroviral vector, a helper virus plasmid and VSVg expression plasmid in HEK293 cells. The virus particles were harvested from the cell culture supernatants and concentrated by ultracentrifugation. The concentrated virus preparations were used to infect either mouse embryonic fibroblasts (MEF) or HEK293 cells which harbor both lacZ and firefly luciferase (Luc) reporter genes. Infection was monitored by the GFP signal which is expressed from the marker gene cassette of the viral vector. Under the conditions of this experiment, >98% of the test cells were GFP+ and thus successfully transduced. The expression levels of lacZ and Luc reporter genes were measured by chemiluminescent assays using commercially available kits (lacZ assay kit from Roche and Luc from Promega). The lacZ siRNA virus only inhibited the expression of lacZ but not Luc. The specific inhibition was determined by the ration of lacZ activity versus Luc activity. The lacZ/Luc ration of the uninfected parental cells was arbitrarily set to 1 and the values of the infected cells were calculated accordingly. As shown in Figure 6, transfection with the virus resulted in dramatic reduction in the amount of expression of the lacZ gene in both MEK and HEK293 cells.

[0135] A tet-iducible lacZ siRN, lentiviral vector was also prepared as illustrated in Figure 8. A Tet repressor gene (TetR; SEQ ID NO: 7) was placed the under the control of the human UbiquitinC promoter so that its expression could be monitored by the downstream GFP marker. The anti-lacZ siRNA cassette was driven by a Tet-inducible

pol III promoter derived from human U6-promoter (-328 to +1) containing a single TetR binding site (TetO1) between the PSE and TATA box (SEQ ID NO: 6). The TetR coding sequence was PCR amplified from genomic DNA from the TOP10 strain of E. coli and cloned into a modified version of FUIGW as a Bgl2-EcoR1 fragment. In the absence of tetracycline, TetR binds to the promoter and its expression is repressed. Upon the addition of tetracycline, TetR is moved from the promoter and transcription starts.

[0136] The Tet-inducible siRNA expression cassette was able to regulate gene expression in response to Doxycycline treatment. Virus was prepared from the retroviral construct carrying the Tet-inducible lacZ-siRNA cassette and a Tet repressor under the control of a UbiquitinC promoter and used to transduce HEK293 cells expressing both lacZ and luciferase (293Z+Luc). The transduced cells were treated with 10 ug/ml Doxycycline (Plus Dox) for 48hr or without the Doxycycline treatment as a control (No Dox). LacZ and luciferase activities were measured as described in the previous figures. The relative suppression activity is calculated as the ratio of lacZ versus luciferase and No Dox control was arbitrarily set to 1. As can be seen in Figure 9, in the presence of doxycycline suppression of lacZ activity was significantly enhanced:

Example 3

[0137] This example demonstrates the generation of transgenic animals that express an siRNA molecule encoded by a lentiviral vector. The expression of the lacZ specific siRNA construct described in Example 1 resulted in extensive suppression of lacZ activity in ROSA26^{+/-} mice. ROSA26^{+/-} animals carry one copy of an ubiquitously expressed lacZ reporter gene. The lacZ siRNA virus preparations described in Example 2 were used for perivitelline injection of ROSA26^{+/-} single cell embryos obtained from hormone primed C57Bl/6 female donors x ROSA26^{+/+} stud males. The injected single cell embryos were subsequently transferred into the oviduct of timed pseudopregnant female recipients. Embryonic day 15.5 to 17.5 (E15.5-17.5) fetuses were recovered from the surrogate mothers. Successful transgenesis was scored by positive GFP signal observed with the fetuses under fluorescent microscope. Protein extracts prepared from the limb tissues of the fetuses were used for the LacZ chemiluminescent assay according to the manufacturer's instruction (Roche), and protein concentrations of the tissue extracts were determined by the Bradford assay (BioRad). The lacZ expression levels were expressed as

light units (LU) per ug of proteins (LU/ug). The E15.5-17.5 fetuses from the timed mating of C57Bl/6 females x ROSA26^{+/+} males and C57Bl/6 females x C57Bl/6 males were served as the positive and negative controls respectively. The results are shown in Figure 7. In animals G1-G4 (those treated with lentiviral vector encoding the siRNA construct), the animals showed markedly decreased expression of the lacZ gene as compared with untreated control animals.

Example 4

[0138] A lentiviral construct comprising an RNA coding region encoding an anti-human CCR5 siRNA was prepared. As illustrated in Figure 10, the vector comprised an HIV based lentiviral vector 5' LTR, an HIV Flap element, a human U6-RNA pol II promoter (-328 to +1; SEQ ID NO: 4), a human CCR5 specific short hairpin RNA cassette, an internal ubiquitin promoter, a GFP marker gene operably linked to the ubiquitin promoter a WRE regulatory element and an HIV based self-inactivating lentiviral 3' LTR. The structure and sequence of the anti-CCR5 siRNA are provided in Figure 10 and SEQ ID NO: 1.

[0139] Recombinant retrovirus was prepared from the anti-CCR5 siRNA vector construct as described above. Human MAGI-CCR5 cells (Deng et al., Nature 381:661 (1996)) were infected with the recombinant virus or a retrovirus encoding a non-specific control siRNA and cell surface expression of CCR5 was measured by flow cytometric analysis. Relative expression levels were calculated by mean fluorescence intensity. As can be seen in Figure 11, the anti-CCR5 siRNA reduced the level of CCR5 expression almost completely, while the non-specific siRNA did not suppress expression at all.

Example 5

[0140] A further anti-HIV-1 siRNA encoding lentiviral vector was constructed, as illustrated in Figure 12. This vector comprised an RNA coding region encoding an anti-HIV-1 Rev gene specific short hairpin siRNA (SEQ ID NO: 2). The anti-HIV-1 Rev siRNA targeted the 8420 to 8468 region of the Rev coding of HIV-1 (nucleotide coordinate of NL4-3 strain; Salminen et al. Virology 213:80-86 (1995)). The sequence and structure of the siRNA coding region are illustrated in Figure 12 as well. Expression of the anti-

HIV-1 Rev siRNA was driven by a human H1-RNA pol III promoter (-240 to -9; SEQ ID NO: 5).

[0141] The ability of the anti-HIV-1 Rev siRNA to suppress HIV transcription in human cells was measured. The transcriptional activity of HIV-1 was measured based on the activity of a firefly luciferase reporter gene inserted at the env/nef region, essentially as described in Li et al. *J. Virol.* 65:3973 (1991)).

[0142] Recombinant retrovirus was prepared from the vector construct as described above and used to infect human cells comprising HIV-1 with the reporter construct. The luciferase activity of untransduced parental cells was arbitrarily set to 1 and the relative HIV transcription levels of the transduced cells were calculated accordingly. A non-specific siRNA was used as a control.

[0143] As can be seen in Figure 13, HIV-1 transcription was significantly suppressed in cells infected with the recombinant retrovirus comprising the anti-HIV-1 Rev siRNA coding region, while the non-specific siRNA had no significant effect.

Example 6

[0144] According to this example, an siRNA lentiviral construct against the HIV genome is constructed by insertion of an siRNA expression cassette into the PacI site of HC-FUGW vector. HC-FUGW vector contains a GFP marker gene driven by human Ubiquitin promoter for tracking transduction events. The vector also contains an HIV DNA Flap element to improve the virus titers, and WPRE for high level expression of viral genes. The siRNA expression cassette is composed of a pol III promoter and a small hairpin RNA coding region followed by a pol III terminator site. The pol III promoter is derived from -240 to -8 region of human H1-RNA promoter and is connected to the downstream RNA coding region through a 7 base pair linker sequence to ensure that the transcription is precisely initiated at the first nucleotide of the RNA coding sequence. The small hairpin RNA coding region contains a 21 nt sequence corresponding to a region of the CCR5 coding sequence and the 21 nt perfect reverse complementary sequence separated by a 4 nt loop region. The terminator is comprised of 5 consecutive thymidine residues linked immediately downstream of the RNA coding sequence.

[0145] The retroviral construct is used to transfect a packaging cell line (HEK293 cells) along with a helper virus plasmid and VSVg expression plasmid. The recombinant viral particles are recovered.

[0146] CD34-positive hematopoietic stem cells are isolated from a patient's bone marrow using an immunomagnetic approach (see, for example, Choi et al.(1995) Blood 85:402-413; Fehse et al. (1997) Human Gene Therapy 8:1815-1824; Di Nicola et al.(1996) Bone Marrow Transplant. 18:1117-1121; Servida et al.(1996) Stem Cells 14:430-438; de Wynter et al.(1995) Stem Cells 13:524-532; Ye et al.(1996) Bone Marrow Transplant. 18:997-1008.). The cells are cultured and treated with the recombinant virus particles. The infected cells are sorted by FACS based on expression of GFP. Those cells expressing GFP are reintroduced into a patient by injection.

Example 7

[0147] According to this example, an siRNA lentiviral construct against the HIV genome is constructed by insertion of an siRNA expression cassette into the PacI site of HC-FUGW vector. The siRNA expression cassette comprises a human H1 promoter operatively linked to an RNA coding region encoding an anti-HIV-1 Rev gene specific short hairpin siRNA. The siRNA expression cassette additionally comprises a pol III promoter operatively linked to a small anti-CCR5 hairpin RNA. The retroviral construct is illustrated in Figure 14.

[0148] The retroviral construct is used to transfect a packaging cell line (HEK293 cells) along with a helper virus plasmid and VSVg expression plasmid. The recombinant viral particles are recovered.

[0149] CD34-positive hematopoietic stem cells are isolated from a patient's bone marrow using an immunomagnetic approach (see, for example, Choi et al.(1995) Blood 85:402-413; Fehse et al. (1997) Human Gene Therapy 8:1815-1824; Di Nicola et al.(1996) Bone Marrow Transplant. 18:1117-1121; Servida et al.(1996) Stem Cells 14:430-438; de Wynter et al.(1995) Stem Cells 13:524-532; Ye et al.(1996) Bone Marrow Transplant. 18:997-1008.). The cells are cultured and treated with the recombinant virus particles. The infected cells are sorted by FACS based on expression of GFP. Those cells expressing GFP are reintroduced into a patient by injection.

What is Claimed is:

1. An *in vitro* method of down regulating gene expression in a cell, comprising:
infecting a target cell with a recombinant retrovirus for expressing a double-stranded RNA duplex, wherein the recombinant retrovirus comprises:
 - a 5' long terminal repeat (LTR) comprising lentiviral R and U5 sequences and a self-inactivating lentiviral 3' LTR;
 - a first promoter operably linked to a first siRNA coding region, wherein the first promoter and the first siRNA coding region are located between the 5' LTR and the 3' LTR;
 - a second promoter operably linked to a second siRNA coding region, wherein the second siRNA coding region encodes a second siRNA capable of hybridizing to the first siRNA to form the double-stranded RNA duplex, and
 - a first termination sequence;

wherein the double-stranded RNA duplex comprises a sequence that is at least 90% identical to a target region of a pathogenic virus genome or genome transcript, or an endogenous target cell gene encoding a product that is involved in the lifecycle of an infecting pathogenic virus,

wherein the target region of the pathogenic virus genome or genome transcript is a region in a human immunodeficiency virus (HIV) LTR, HIV vif gene, HIV nef gene, HIV rev gene, HIV gag gene, or HIV pol gene, or a transcript thereof; and

wherein the product encoded by the endogenous target cell gene is CD4, cyclophilin, CRM-1, importin- β , HP68, or a cellular receptor that is involved in recognition by an Adenovirus, Cytomegalovirus (CMV), Coxsackievirus, hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), HIV, herpes simplex virus (HSV), influenza virus, Measles virus, poliovirus, human papillomavirus, or a combination thereof.

2. The method of claim 1, wherein the first siRNA coding region comprises a sequence that is at least 95% identical to the sequence of the target region or the target cell gene.

3. The method of claim 1 or 2, wherein the first promoter is a RNA polymerase III promoter.

4. The method of any one of claims 1-3, wherein the target region is a region in HIV vif gene, HIV nef gene, HIV rev gene, HIV gag gene, or HIV pol gene.

5. The method of any one of claims 1-3, wherein the endogenous target cell gene encodes CD4, cyclophilin, CRM-1, importin- β , or HP68.

6. The method of any one of claims 1-3, wherein the product encoded by the endogenous target cell gene is a cellular receptor that is involved in recognition by a virus selected from the group consisting of adenoviruses, cytomegalovirus, coxsackieviruses, hepatitis A virus, hepatitis C virus, HIV, HSV, influenza virus, measles virus, poliovirus, and human papillomavirus.

7. The method of any one of claims 1-3, wherein the product encoded by the endogenous target cell gene is a cellular receptor selected from the group consisting of CAR, integrins, MHC I, Heparan sulfate glycosaminoglycan, Sialic acid, ICAM-1, murine-like class I integral membrane glycoprotein, CD81, low density lipoprotein receptor, PVR, HveB, HveC, CD46, and CD55.

8. The method of any one of claims 1-7, wherein the target cell is present in a cell culture.

9. The method of any one of claims 1-8, wherein the target cell is a CD34-positive cell.

10. The method of any one of claims 1-8, wherein the target cell is a CD4-positive cell.

11. The method of any one of claims 1-8, wherein the target cell is a hematopoietic cell.

12. The method of any one of claims 1-11, wherein the first siRNA coding region encodes an siRNA having a sense region, an antisense region and a loop region, and wherein the sense region is complementary to the antisense region.

13. The method of claim 12, wherein the loop region is 2 to 15 nucleotides in length.

14. The method of any one of claims 1-13, wherein the retroviral construct further comprises a second RNA polymerase III promoter region operably linked to the first siRNA coding region, such that expression of the first siRNA coding region from the first RNA polymerase III promoter region results in a synthesis of a first siRNA and expression of the first siRNA coding region from the second RNA polymerase III promoter region results in synthesis of a second siRNA complementary to the first siRNA.

15. The method of any one of claims 1-14, wherein the lentiviral R and U5 sequences are from HIV.

16. The method of any one of claims 1-15, wherein the self-inactivating 3' LTR comprises a U3 element with a deletion of its enhancer sequence.

17. The method of claim 16, wherein the self-inactivating 3' LTR is a pseudotyped HIV 3' LTR.

18. The method of any one of claims 1-17, wherein the recombinant retrovirus is pseudotyped.

19. The method of claim 18, wherein the recombinant retrovirus is pseudotyped with the vesicular stomatitis virus envelope glycoprotein.

20. The method of any one of claims 1-19, wherein the lentiviral R and U5 sequences are from Moloney Murine Leukemia Virus.

21. The method of any one of claims 1-19, wherein the lentiviral R and U5 sequences are from murine stem cell virus (MSCV).
