VALVE FOR HYDRAULIC FRACTURING THROUGH CEMENT OUTSIDE CASING

A valve for use in fracturing through cement casing in a well allows for flow of cement down the well during the cementing process and in the open position allows for fracturing fluid to be directed through the cement casing for fracturing the formation adjacent the valve. The valve is constructed so as to reduce the likelihood of the valve to jam as a result of cement or other foreign material.
Background of Invention

This invention is directed to a valve utilized for hydraulically fracturing multiple zones in an oil and gas well without perforating the cement casing. A relatively new oil/gas well completion method involves the use of a valve that is installed as part of the casing string of the well and provides for cement flow within the casing when the valve element is string of the well, and provides for cement flow within the casing when the valve element is in a closed position and allows for axial flow of fracturing fluid through the cement casing to in a closed position and allows for axial flow of fracturing fluid through the cement casing to fracture the formation near the valve. The invention disclosed herein is an improved valve used in this process.

Description of Related Art

Current designs for valves used in the completion method disclosed above are prone to failure because cement or other debris interferes with the opening of the valve after the cementing process has been completed. Portions of the sliding sleeve or pistons commonly used are exposed to either the flow of cement or the cement flowing between the wellbore and the casing string.

BRIEF SUMMARY OF THE INVENTION

The valve, according to the invention, overcomes the difficulties described above by isolating a sliding sleeve between an outer housing and an inner mandrel. A rupture disk in the inner mandrel ruptures at a selected pressure. Pressure will then act against one end of the sliding sleeve, and shift the sleeve to an open position so that fracturing fluid will be directed against the cement casing. The sliding sleeve includes a locking ring nut to prevent the sleeve from sliding back to a closed position.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING(S)

FIG. 1 is a side view of the valve according to one embodiment of the invention.

FIG. 2 is a cross sectional view of the valve in the closed position taken along line 2-2 of FIG. 1.

FIG. 3 is a cross sectional view of the valve taken along line 3-3 of FIG. 2.

FIG. 4 is a cross sectional view of the sliding sleeve.

FIG. 5 is a cross sectional view of the locking ring holder.

FIG. 6 is a cross sectional view of the locking ring holder.

FIG. 7 is an end view of the locking ring holder.

FIG. 8 is a cross sectional view of the valve in the open position.

FIG. 9 is an enlarged view of the area circled in FIG. 8.
DETAILED DESCRIPTION OF THE INVENTION

As shown in FIG. 1, an embodiment of valve 10 of the invention includes a main housing 12, and two similar end connector portions 11 and 14, that receive threaded portions 61 at each end that receive threaded portions 61 of each end connector. End connectors 11 and 14 may be internally or externally threaded for connection to the casing string. As shown in FIG. 2, main housing 13 includes one or more openings 12, which are surrounded by a circular protective cover 40. Cover 40 is made of a high impact strength material.

Valve 10 includes a mandrel 30 which is formed as a hollow cylindrical tube extending between end connectors 11, 12 as shown in FIG. 2. Mandrel 30 includes one or more apertures 23 that extend through the outer wall of the mandrel. Mandrel 30 also has one or more apertures 23 that extend through the outer wall of the mandrel. Mandrel 30 also has an external intermediate threaded portion 51. One or more rupture disks 41, 42, are located in exterior intermediate threaded portion 51. One or more rupture disks 41, 42 are located in the main housing, as shown in FIG. 3. Rupture disks 41, 42 are located within passageways that extend between the inner and outer surface of the mandrel 30. Annular recesses 17 and 27 are provided in the outer surface of the mandrel for receiving suitable seals.

Mandrel 30 is confined between end connectors 11 and 12 by engaging a shoulder 15 in the inner interior surface of the end connectors. End connectors 11 and 12 include longitudinally extending portions 18 that space apart outer housing 13 and mandrel 30 thus forming a chamber 36. Portions 18 have an annular recess 32 for relieving a suitable seal. A sliding sleeve member 20 is located within chamber 36 and is generally of a hollow cylindrical configuration, as shown in FIG. 4. The sliding sleeve member 20 includes an annular small diameter portion 24 that is threaded at 66. Also, it is provided with indentations 43 on the outer surface that are received in slots 44. Indentations 43 that receive the end portions of shear pins 21. Sliding sleeve member 20 also includes openings 25 that accommodate suitable annular seals.

A locking ring holder 25 has sufficient diameter clearance so that the locking ring can ratchet on the mandrel ratcheting teeth 63 yet leave sufficient contact with the locking ring holder. A locking ring holder 25 has ratchet teeth 63 on its outer surface and ratchet teeth 55 on its inner surface shown in FIG. 9. Ratchet teeth 51 on its outer surface and ratchet teeth 55 on its inner surface shown in FIG. 9. Locking ring 50 includes an opening at 91 as shown in FIG. 7 which allows it to grow in diameter as the sliding sleeve moves from the closed to open position.

Locking ring holder 25 has sufficient diameter clearance so that the locking ring can ratchet on the mandrel ratcheting teeth 63 yet leave sufficient contact with the lock ring holder. A locking ring holder 25 is threaded at 26 for engagement with threads 24 on the mandrel. Locking ring holder 25 also includes a plurality of bores 46 and 62 for set screws, not shown. In use, valve 10 may be connected to the casing string by end connectors 11, 12. One or more valves/10 may be incorporated into the casing string. After the casing string is deployed within the wellbore, cement is pumped down through the casing and out the bottom.
into the annulus between the well bore and the casing as typical in the art. After the cement flow is terminated, a plug or other device is pumped down to wipe the casing and valve clean of residual cement. When the plug or other device has latched or sealed in the bottom hole assembly, pressure is increased to rupture the rupture disk at a predetermined pressure. The fluid pressure will act on sliding sleeve member 20 to cause the shear pins to break and then move it downward or to the right as shown in FIG. 7. This movement will allow frac ing fluid to exit via opening 23 in the mandrel and openings 19 in the outer housing. The frac ing fluid under pressure will remove protective cover 40 and crack the cement casing and also fracture the foundation adjacent to the valve 10.

Due to the fact that the sliding sleeve member 20 is mostly isolated from the cement flow, the sleeve will have a lessor tendency to jam or require more pressure for actuation. In the open position, locking ring 50 engages threads 63 on the mandrel to prevent the sleeve from moving back to the closed position. A vent 37 is located in the outer housing 13 to allow air to exit when the valve is being assembled. The vent 37 is closed by a suitable plug after assembly.

Although the present invention has been described with respect to specific details, it is not intended that such details should be regarded as limitations on the scope of the invention, except to the extent that they are included in the accompanying claims.
CLAIMS

What is claimed is:

What is claimed is comprising:

1. A valve comprising:
   a. a housing having an opening,
   b. a mandrel positioned within the housing and having an opening,
   c. a sliding sleeve disposed between the housing and the mandrel and blocking a fluid communication between the opening in the housing and the opening in the mandrel,
   d. and blocking a fluid communication between the opening in the housing and the opening in the mandrel when the valve is in the closed position and permitting fluid flow between the openings in the mandrel and the openings in the housing when the valve is in the open position, and
   e. the chamber between them in which the sliding sleeve is disposed.

2. A valve as claimed in claim 1, wherein the rupture disk is disposed in a wall.

3. A valve as claimed in claim 1, including an end connector on each end of the housing for connection to a casing string in an oil or gas well.

4. A valve as claimed in claim 1, further including a protective sleeve covering the openings in the housing.

5. A valve as claimed in claim 1, wherein the housing and mandrel define a chamber between them in which the sliding sleeve is disposed.

6. A method for actuating a valve, the method comprising:
   a. a housing having one or more openings;
   b. a mandrel having one or more openings;
   c. a sliding sleeve disposed between the housing and the mandrel and blocking fluid communication between the opening in the housing and the opening in the mandrel when the valve is in the closed position and permitting fluid flow between the openings in the mandrel and the openings in the housing when the valve is in the open position; and
   d. and blocking fluid communication between the opening in the housing and the opening in the mandrel when the valve is in the closed position and permitting fluid flow between the openings in the mandrel and the openings in the housing when the valve is in the open position; and
   e. a rupture disk that, upon rupture, permits application of a fluid pressure to move the sliding sleeve between the open and closed positions; and
   f. a sleeve between the open and closed positions; and
   g. moving the sliding sleeve responsive to the fluid pressure between the open and closed positions; and
   h. exiting fluid through the one or more openings of the housing and mandrel.
7. The method of claim 6, further comprising cracking a cement casing with the fluid.
8. The method of claim 6, further comprising pumping cement through the valve into a wellbore.
9. The method of claim 8, further comprising wiping the valve with a plug.
10. The method of claim 8, wherein the sliding sleeve is isolated between the housing and the mandrel.
11. A casing string valve for use in fracturing operations, comprising:
   a housing having a first opening thereon fluidly connecting the exterior of the wellbore within the housing to define in conjunction with the housing a chamber isolated from the cement flow path;
   a sliding sleeve blocking and unblocking the fracturing fluid flow path, the sliding sleeve disposed between the housing and the mandrel, at least partially isolated from the cement flow path within the chamber, and actuated by application of fluid pressure applied through the bore and the third opening.
12. The casing string valve of claim 11, further comprising a rupture disk disposed within the third opening to selectively control the application of fluid pressure through the third opening.
13. A casing string valve as claimed in claim 11, including an end connector on each end of the housing for connection in a casing string in an oil or gas well.
14. A casing string valve as claimed in claim 11, further including a protective sleeve covering the openings in the housing.
15. A method for use in hydraulically fracturing a well, comprising:
   disposing a casing string in a wellbore, the casing string including a valve defining a cement flow path and a fracturing fluid flow path therethrough, the fracturing fluid flow path being blocked and unblocked by a sliding sleeve of the valve at least partially isolated from the cement flow path;
   cementing the casing string within the wellbore through the cement flow path while the fracturing fluid flow path is blocked; hydraulically fracturing the wellbore through the cement flow path while the fracturing fluid flow path is blocked; and applying fluid pressure through the bore of the valve to actuate the sliding sleeve and unblock the fracturing fluid flow path; and bore of the valve to actuate the sliding sleeve and unblock the fracturing fluid flow path; and
introducing a fracturing fluid into the well bore through the fracturing fluid flow path. 

16. The method of claim 15, wherein the sliding sleeve is at least partially isolated.

17. The method of claim 15, further comprising cracking a cement casing with the introduced fracturing fluid.

18. The method of claim 15, further comprising wiping the valve with a plug after the cementing and prior to applying the fluid pressure.

19. The method of claim 15 wherein applying the fluid pressure includes rupturing a rupture disk.
