(54) Titre : METHODE ET SUPPORT LISIBLE PAR ORDINATEUR PERMETTANT DE VERIFIER ET DE
SAUVEGARDER UN DOCUMENT ELECTRONIQUE
(54) Title: METHOD AND COMPUTER-READABLE MEDIUM FOR VERIFYING AND SAVING AN ELECTRONIC
DOCUMENT

(57) Abrégé/Abstract:

A method and computer-readable medium are provided for saving the contents of a memory structure stored in a volatile memory. According to the method, corrupted portions of the memory structure are identified and an attempt is made to repair these portions. If the corrupted portions cannot be repaired, the saving of these portions is skipped. The uncorrupted and repaired portions of the memory structure are then saved to a data file stored on a mass storage device. If portions of the memory structure cannot be repaired or skipped, an attempt is made to save only the user data contained in the memory structure to the data file. In this manner, the user data contained in the memory structure may be saved to a data file even in cases of severe corruption.

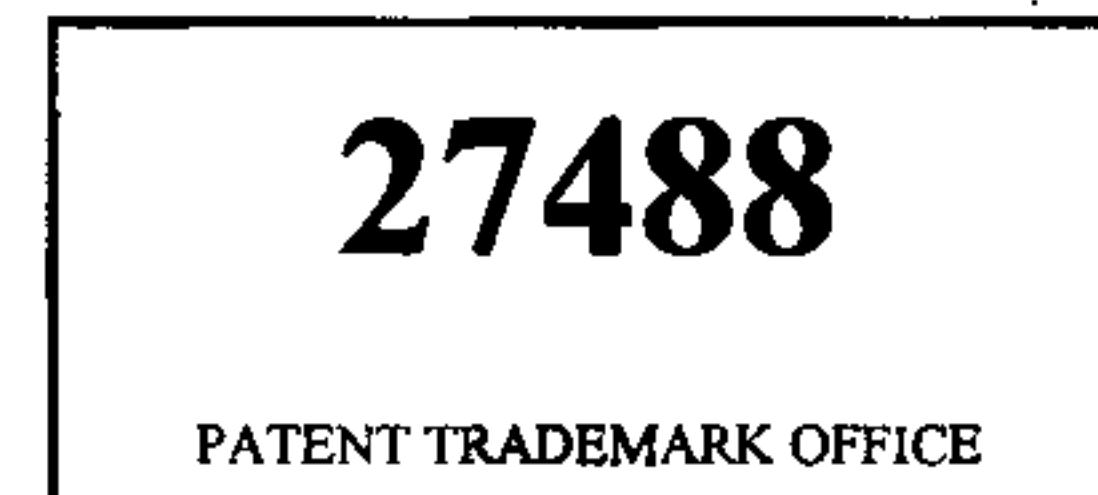

METHOD AND COMPUTER-READABLE MEDIUM FOR
VERIFYING AND SAVING AN ELECTRONIC DOCUMENT

ABSTRACT OF THE DISCLOSURE

5 A method and computer-readable medium are provided for saving the contents of a memory structure stored in a volatile memory. According to the method, corrupted portions of the memory structure are identified and an attempt is made to repair these portions. If the corrupted portions cannot be repaired, the saving of these portions is skipped. The uncorrupted and repaired portions of the memory structure are then
10 saved to a data file stored on a mass storage device. If portions of the memory structure cannot be repaired or skipped, an attempt is made to save only the user data contained in the memory structure to the data file. In this manner, the user data contained in the memory structure may be saved to a data file even in cases of severe corruption.

METHOD AND COMPUTER-READABLE MEDIUM FOR
VERIFYING AND SAVING AN ELECTRONIC DOCUMENT

BACKGROUND OF THE INVENTION

5 Computers are utilized pervasively in today's society to perform a wide variety of tasks and for entertainment purposes. For instance, computers today are utilized for gaming, communications, research, and a virtually endless variety of other applications. One of the most common uses of computers, by both businesses and individuals alike, is the creation of electronic and printed documents. Computer
10 application programs exist for creating all kinds of electronic documents, including spreadsheets, presentations, word processing documents, graphical documents such as diagrams and digital images, computer-aided design documents, and many other types of electronic documents.

15 Electronic documents often include content that is very important. Moreover, the content of an electronic document in many cases would be difficult or impossible to recreate if lost. For instance, highly complicated legal, business, marketing, and technical documents are often created that could not easily be recreated if the data file storing the document were corrupted or destroyed. Even in cases where the contents of a document could be easily be recreated, it can be very frustrating for a
20 user to lose even a small portion of their data. Accordingly, it is very important that the data contained in electronic documents be protected against destruction and corruption.

 Modern computer systems include error checking and other mechanisms to protect against the inadvertent corruption or loss of system memory. Unfortunately,

51028-108

even with these mechanisms in place, it is possible for a document stored in volatile system memory to become corrupted prior to saving the document to a data file on a mass storage device. Corruption may occur as the result of faulty memory, a faulty memory controller, memory management errors, loading faulty or corrupt data, a crash 5 of the application program, and for other reasons. Because the loss of any amount of data can be frustrating to a user and because the time and effort necessary to recreate a corrupted document is often very great, it is important that as much data as possible be recovered from a corrupted document stored in volatile memory prior to saving the contents of the memory to a mass storage device.

10 It is with respect to these considerations and others that the various embodiments of the present invention have been made.

BRIEF SUMMARY OF THE INVENTION

In accordance with some aspects of the present invention, the above and other problems may be solved by a method and computer-readable medium for saving 15 the contents of a document stored in a memory structure in a volatile memory to a data file stored on a mass storage device. Through the use of the various embodiments of the present invention, corrupted portions (also called "records") of the memory structure are identified during the save of a memory structure and an attempt is made to repair these portions. If the corrupted portions cannot be repaired, the saving of the corrupted 20 portions is skipped. The uncorrupted and repaired portions of the memory structure are then saved to a data file on a mass storage device. If portions of the memory structure cannot be repaired or skipped, an attempt is made to save only the user data contained in the memory structure. In this manner, the user data contained in the memory structure may be saved to mass storage even in cases of severe corruption to the 25 remainder of the memory structure.

According to one aspect of the invention, a method is provided for saving a memory structure stored in a volatile memory that includes one or more portions to a data file on a mass storage device. According to the method, a number of save modes are provided. In the "normal" save mode an attempt is made to save each

51028-108

portion of the memory structure in a normal fashion. The normal save mode includes minimal integrity checking on each of the portions of the memory structure so that the data can be saved quickly. If a portion of the memory structure is encountered that is missing or corrupt while in the normal mode, a second mode, called the "safe" save 5 mode, is utilized to attempt to save the portions of the memory structure. A portion of the memory structure may be considered corrupt and therefore unsaveable if it causes an error in or crash of the application program attempting to save it, if the portion includes an unexpected data value, if the portion is missing data, if the portion includes invalid records or invalid extensible markup language ("XML"), and for other causes.

10 In the safe save mode extensive integrity checking is performed on each portion of the memory structure. In the safe save mode an attempt may also be made to repair the corrupted portions of the memory structure. Any portions that can be repaired are then saved. If a portion of the memory structure is encountered in the safe save mode that is missing or corrupt and which is also unrepairable, the saving of the 15 unrepairable portion is skipped. If portions of the memory structure are encountered that are not repairable and for which saving cannot be skipped, a third save mode, called the "minimal" save mode, is utilized to attempt to save certain portions of the memory structure.

20 In the minimal save mode only the portions of the memory structure that include user data are saved. For instance, user data may comprise text data or numerical data that was entered by a user. As an example, if the memory structure contains data for a spreadsheet, an attempt is made in the minimal save mode to save only the data contained in the cells of the spreadsheet. No attempt is made in the minimal mode to save other types of data that may be contained in the memory 25 structure such as embedded objects, pivot tables, auto filters, graphics, styles, formatting, and application or user preferences.

51028-108

According to one aspect of the present invention, there is provided a method for saving the contents of a memory structure stored in a volatile memory and having one or more portions to a data file on a mass storage device, the method comprising: attempting to save each portion of the memory structure in a first mode, wherein in the first mode minimal integrity checking is performed on each of the portions; determining in the first mode by said minimal integrity checking whether a portion of the data file is unsaveable; and in response to determining that a portion is unsaveable, attempting to save the contents of the memory structure in a second mode wherein more extensive integrity checking is performed on each of the portions and wherein saving of each unsaveable portion is skipped wherein while attempting to save the contents of the memory structure in the second mode a determination is made as to whether an unsaveable portion may be repaired, and in response to determining that an unsaveable portion may be repaired, repairing the unsaveable portion and saving the repaired portion to the data file.

According to another aspect of the present invention, there is provided a computer-readable storage medium having computer-executable instructions stored thereon which, when executed by a computer, will cause the computer to: provide a first saving mode for saving the contents of a memory structure having one or more portions from a volatile memory to a data file on a mass storage device, wherein minimal integrity checking is performed on each of the portions when saving in the first saving mode; provide a second saving mode for saving the contents of the memory structure to the data file, wherein more extensive integrity checking is performed on each of the portions and wherein saving of each unsaveable portion is skipped; begin saving the contents of the memory structure in the first saving mode; and determine when operating in the first saving mode by said minimal integrity checking whether a portion of the memory structure is unsaveable and in response to determining that a portion is unsaveable, switching to the second saving mode wherein in the second saving mode a determination is made as to whether an unsaveable portion may be repaired, and in response to determining that an unsaveable portion may be repaired, repairing the unsaveable portion and saving the repaired portion to the data file.

According to still another aspect of the present invention, there is provided a computer-readable medium having computer-executable instructions stored thereon which,

51028-108

when executed by a computer, will cause the computer to: provide a first saving mode, a second saving mode, and a third saving mode; begin saving the contents of a memory structure having a plurality of data records in the first saving mode, wherein minimal integrity checking is performed on the at least one data record; determine, by said minimal integrity

5 checking, while saving the contents of the memory structure in the first saving mode whether the at least one of the plurality of data records is unsaveable; in response to determining in the first saving mode that at least one of the plurality of data records is unsaveable, switch to the second saving mode; attempt to save the contents of the memory structure from its beginning in the second saving mode, wherein in the second saving mode additional integrity checks are
10 performed on the plurality of data records as compared to the first mode; determine if the at least one unsaveable data record can be repaired; in response to determining that the at least one unsaveable data record can be repaired, repair the at least one unsaveable data record and saving the at least one repaired data record; in response to determining that the at least one unsaveable data records cannot be repaired, skip the at least one unsaveable and unrepairable
15 data record; determine while saving the contents of the memory structure in the second saving mode whether the saving of the at least one unsaveable and unrepairable data records cannot be skipped; and in response to determining that the saving of the at least one unsaveable data record cannot be skipped while saving in the second saving mode, switch to the third saving mode wherein only user data stored in the memory structure is saved.

20 According to yet another aspect of the present invention, there is provided a method for saving the contents of a memory structure comprising a plurality of data records to a data file located on a mass storage device, the method comprising: providing a first saving mode, a second saving mode, and a third saving mode; attempting to save the contents of the memory structure to the data file in the first saving mode, wherein minimal integrity checking
25 is performed on the plurality of data records while saving in the first saving mode; determining, by said minimal integrity checking, while saving the memory structure in the first saving mode whether at least one of the plurality of data records is unsaveable; in response to determining in the first saving mode that at least one of the plurality of data records is unsaveable, switching to the second saving mode; attempting to save the memory
30 structure from its beginning in the second saving mode, wherein in the second saving mode

51028-108

additional integrity checks are performed on the plurality of data records as compared to the first mode; determining if the at least one unsaveable data record can be repaired; in response to determining that the at least one unsaveable data record can be repaired, repairing the at least one unsaveable data record and saving the at least one repaired data record; in response to determining that the at least one unsaveable data records cannot be repaired, skipping the at least one unsaveable and unrepairable data record; determining while saving the memory structure in the second saving mode whether the saving of at least one of the plurality of data records cannot be skipped; and in response to determining that the saving of at least one of the plurality of data records cannot be skipped while saving in the second saving mode, switching to the third saving mode wherein only the plurality of data records comprising user data stored in the memory structure is saved.

According to a further aspect of the present invention, there is provided a method for saving the contents of a memory structure comprising a plurality of data records to a data file located on a mass storage device, the method comprising: providing a first saving mode, a second saving mode, and a third saving mode; attempting to save the contents of the memory structure to the data file in the first saving mode, wherein minimal integrity checking is performed on the plurality of data records while saving in the first saving mode; determining, by said minimal integrity checking, while saving the memory structure in the first saving mode whether at least one of the plurality of data records is unsaveable, wherein a data record is unsaveable if it includes an unexpected data value, is missing data, includes invalid extensible markup language, causes an application program to crash when saving the record, is corrupt, or if the record is missing; in response to determining in the first saving mode that at least one of the plurality of data records is unsaveable, switching to the second saving mode; attempting to save the memory structure from its beginning in the second saving mode, wherein in the second saving mode additional integrity checks are performed on the plurality of data records as compared to the first mode; determining whether the at least one of the plurality of data records that is unsaveable can be repaired; in response to determining that the at least one of the plurality of data records that is unsaveable can be repaired: repairing the at least one of the plurality of data records that is unsaveable; and saving the at least one of the plurality of data records that has been repaired; in response to determining that the at least

51028-108

one of the plurality of data records that is unsaveable cannot be repaired, skipping the saving of the at least one of the plurality of data records that is unsaveable and unrepairable; determining while saving the memory structure in the second saving mode whether the saving of at least one of the plurality of data records cannot be skipped; and in response to

5 determining that the saving of at least one of the plurality of data records cannot be skipped while saving in the second saving mode, switching to the third saving mode, wherein the third saving mode comprises: determining whether any of the plurality of data records comprise user data, wherein user data comprises at least one of text data, numerical data, formulas, and formula generated data; determining whether any of the plurality of data records comprising

10 user data stored in the memory structure are missing or corrupt; and saving each of the plurality of data records comprising user data stored in the memory structure that is not missing or corrupt.

According to yet a further aspect of the present invention, there is provided a method for saving the contents of a memory structure stored in a volatile memory and having one or more portions to a data file on a mass storage device, the method comprising:

15 attempting to save each portion of the memory structure in a first saving mode, wherein in the first mode minimal integrity checking is performed on each of the portions to determine whether a portion of the data file is corrupted; and in response to determining that a portion is corrupted, attempting to save the contents of the memory structure in a second saving mode

20 wherein more extensive integrity checking is performed on each of the portions to determine as to whether a corrupted portion may be repaired and in response to determining that a corrupted portion may not be repaired, skipping the saving of the corrupted portion.

According to still a further aspect of the present invention, there is provided a computer-readable medium having computer-executable instructions stored thereon which,

25 when executed by a computer, will cause the computer to: provide a first saving mode for saving the contents of a memory structure having one or more portions from a volatile memory to a data file on a mass storage device, wherein minimal integrity checking is performed on each of the portions to determine whether a portion of the data file is corrupted when saving in the first saving mode; provide a second saving mode for saving the contents of

30 the memory structure to the data file, wherein more extensive integrity checking is performed

51028-108

on each of the portions to determine as to whether a corrupted portion may be repaired, wherein in the second saving mode the saving of the corrupted portion is skipped in response to determining that the corrupted portion may not be repaired, begin saving the contents of the memory structure in the first saving mode; and in response to determining that a portion is

5 corrupted, switching to the second saving mode.

According to other embodiments of the invention, a computer-readable medium is also provided on which is stored computer-executable instructions. When the computer-executable instructions are executed by a computer, they cause the computer to provide a first saving mode for saving the contents of a memory structure

that has one or more portions. In the first saving mode minimal integrity checking is performed on the portions of the memory structure as they are saved to a data file on a mass storage device. The computer-executable instructions also cause the computer to provide a second saving mode for saving the memory structure in which more extensive 5 integrity checking is performed on the portions of the memory structure than in the first saving mode. In the second saving mode an attempt may also be made to repair portions that are unsaveable. Moreover, in the second saving mode the saving of any unsaveable portions is skipped.

The computer-executable instructions also cause the computer to begin 10 saving the contents of a memory structure in the first saving mode. If a portion of the memory structure is determined to be unsaveable in the first saving mode, the computer switches to the second saving mode and attempts to save the memory structure in this saving mode. If, in the second saving mode, an unsaveable portion is encountered that may be repaired, the unsaveable portion is repaired and saved. If the unsaveable portion 15 cannot be repaired, saving of the unsaveable portion is skipped.

According to an embodiment of the invention, the computer-executable instructions also cause the computer to provide a third saving mode wherein only the portions of the memory structure that include user data are saved. If, in the second saving mode, it is determined that a portion of the memory structure is unsaveable and 20 that the unsaveable portion cannot be repaired or skipped, an attempt is made to save the contents of the memory structure in the third saving mode.

The invention may be implemented as a computer process, a computing system, or as an article of manufacture such as a computer program product or computer readable media. The computer program product may be a computer storage 25 media readable by a computer system and encoding a computer program of instructions for executing a computer process. The computer program product may also be a propagated signal on a carrier readable by a computing system and encoding a computer program of instructions for executing a computer process.

These and various other features, as well as advantages, which characterize the present invention, will be apparent from a reading of the following detailed description and a review of the associated drawings.

5 BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

FIGURE 1 is a computer system architecture diagram illustrating a computer system utilized in and provided by the various embodiments of the invention;

FIGURE 2 is a block diagram illustrating aspects of a memory structure and the various saving modes provided by the embodiments of the invention; and

10 FIGURES 3A-3B are flow diagrams showing an illustrative process for saving a memory structure according to the various embodiments of the invention.

DETAILED DESCRIPTION OF THE INVENTION

Referring now to the drawings, in which like numerals represent like elements, various aspects of the present invention will be described. In particular, 15 FIGURE 1 and the corresponding discussion are intended to provide a brief, general description of a suitable computing environment in which embodiments of the invention may be implemented. While the invention will be described in the general context of program modules that execute on an operating system on a personal computer, those skilled in the art will recognize that the invention may also be implemented in 20 combination with other types of computer systems and program modules.

Generally, program modules include routines, programs, components, data structures, and other types of structures that perform particular tasks or implement particular abstract data types. Moreover, those skilled in the art will appreciate that the invention may be practiced with other computer system configurations, including hand-held devices, multiprocessor systems, microprocessor-based or programmable consumer electronics, minicomputers, mainframe computers, and the like. The invention may also be practiced in distributed computing environments where tasks are performed by remote processing devices that are linked through a communications

network. In a distributed computing environment, program modules may be located in both local and remote memory storage devices.

Referring now to FIGURE 1, an illustrative computer architecture for a computer 2 utilized in the various embodiments of the invention will be described. The 5 computer architecture shown in FIGURE 1 illustrates a conventional desktop or laptop computer, including a central processing unit 5 ("CPU"), a system memory 7, including a random access memory 9 ("RAM") and a read-only memory ("ROM") 11, and a system bus 12 that couples the memory to the CPU 5. A basic input/output system containing the basic routines that help to transfer information between elements within 10 the computer, such as during startup, is stored in the ROM 11. The computer 2 further includes a mass storage device 14 for storing an operating system 16, application programs, and other program modules, which will be described in greater detail below.

The mass storage device 14 is connected to the CPU 5 through a mass storage controller (not shown) connected to the bus 12. The mass storage device 14 and 15 its associated computer-readable media provide non-volatile storage for the computer 2. Although the description of computer-readable media contained herein refers to a mass storage device, such as a hard disk or CD-ROM drive, it should be appreciated by those skilled in the art that computer-readable media can be any available media that can be accessed by the computer 2.

20 By way of example, and not limitation, computer-readable media may comprise computer storage media and communication media. Computer storage media includes volatile and non-volatile, removable and non-removable media implemented in any method or technology for storage of information such as computer-readable instructions, data structures, program modules or other data. Computer storage media 25 includes, but is not limited to, RAM, ROM, EPROM, EEPROM, flash memory or other solid state memory technology, CD-ROM, digital versatile disks ("DVD"), or other optical storage, magnetic cassettes, magnetic tape, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store the desired information and which can be accessed by the computer 2.

According to various embodiments of the invention, the computer 2 may operate in a networked environment using logical connections to remote computers through a network 18, such as the Internet. The computer 2 may connect to the network 18 through a network interface unit 20 connected to the bus 12. It should be 5 appreciated that the network interface unit 20 may also be utilized to connect to other types of networks and remote computer systems. The computer 2 may also include an input/output controller 22 for receiving and processing input from a number of other devices, including a keyboard, mouse, or electronic stylus (not shown in FIGURE 1). Similarly, an input/output controller 22 may provide output to a display screen, a 10 printer, or other type of output device.

As mentioned briefly above, a number of program modules and data files may be stored in the mass storage device 14 and RAM 9 of the computer 2, including an operating system 16 suitable for controlling the operation of a networked personal computer, such as the WINDOWS XP operating system from MICROSOFT 15 CORPORATION of Redmond, Washington. The mass storage device 14 and RAM 9 may also store one or more program modules. In particular, the mass storage device 14 and the RAM 9 may store a spreadsheet application program 10. As known to those skilled in the art, the spreadsheet application program 10 is operative to provide functionality for creating and editing electronic spreadsheets.

According to one embodiment of the invention, the spreadsheet application program 10 comprises the EXCEL spreadsheet application program from MICROSOFT CORPORATION. It should be appreciated, however, that other spreadsheet application programs from other manufacturers may be utilized to embody the various aspects of the present invention. It should also be appreciated that although 20 the embodiments of the invention described herein are presented in the context of a spreadsheet application program, the invention may be utilized with any other type of application program that saves data to a data file. For instance, the embodiments of the invention described herein may be utilized within a word processing application program, a presentation application program, a drawing or computer-aided design 25 application program, or a database application program.

As shown in FIGURE 1, portions of the spreadsheet application program 10 may be loaded into the volatile RAM 9 during execution. Moreover, in conjunction with the creation and editing of a spreadsheet document, the spreadsheet application program 10 may utilize a portion of the RAM 9 to store the document. In particular, the 5 spreadsheet application program 10 may utilize one or more memory structures 25 to store data representing the spreadsheet document. From time to time, either in response to a user request or in an automated fashion, the spreadsheet application program 10 is operative to save the contents of the memory structures 25 to a data file 24 stored on the mass storage device 14. The data file 24 contains data representing the various aspects 10 of a spreadsheet document, such as user data including the contents of the spreadsheet cells, application preferences, formatting information, and other data corresponding to the various features provided by the spreadsheet application program 10. As will be described in greater detail below with respect to FIGURES 2-3B, a method for saving the contents of the memory structures 25 to the data file 24 is utilized by the spreadsheet 15 application program 10 that accounts for the possibility of corruption in the memory structures 25 and that attempts to maximize the amount of user data that is saved to the data file 24 even if the memory structures 25 become corrupted.

Turning now to FIGURE 2, additional details will be provided regarding the contents of the memory structures 25 and the operation of the saving mechanism 20 utilized by the spreadsheet application program 10. As shown in FIGURE 2, the memory structures 25 are subdivided into a number of portions 26A-26N. Each of the portions 26A-26N is utilized to store information relating to one or more features supported by the spreadsheet application program 10. Moreover, the information for different but related features may be stored in a single one of the portions 26A-26N. 25 For instance, as shown in FIGURE 2, the data for features A-C are stored in the portion 26A. The data for feature D is stored in portion 26B. The data for features E-G are stored in the portion 26C, and so on. User data may be stored in any of the portions 26A-26N. It should be appreciated that the data stored in the memory structures 25 may 30 be stored in a non-contiguous fashion and that data for related features may be stored in separate memory locations.

As described briefly above, and shown in FIGURE 2, it is possible for the data contained within the portions 26A-26N to be corrupted. Corruption may occur as the result of faulty memory, a faulty memory controller, memory management errors, loading faulty or corrupt data, a crash of the application program, and for other reasons

5 The data for a particular portion may also be determined to be missing. A portion of the memory structures 25 may be considered corrupt and therefore unsaveable if the portion causes an error in or crash of the application program attempting to save it, if the portion includes an unexpected data value, if the portion is missing data, if the portion includes invalid records or invalid extensible markup language (“XML”), and for other

10 causes. In the illustrative memory structures 25 shown in FIGURE 2, the portions 26B and 26D have become corrupted.

As described herein, portions of the memory structures 25 are saveable by the spreadsheet application program 10 despite the corruption of the portions 26B and 26D. FIGURE 2 also illustrates this saving process utilizing the illustrative

15 memory structures 25. In particular, the spreadsheet application program 10 begins saving the memory structures 25 in a normal saving mode. In the normal saving mode, minimal integrity checking is performed on the portions 26A-26N of the memory structures 25. If a corrupted portion of the memory structures 25 is encountered while saving in the normal mode, the spreadsheet application program 10 switches to a safe

20 saving mode and begins saving the memory structures 25 from the beginning. For instance, as shown in FIGURE 2, when the corrupted portion 26B is encountered in the normal saving mode, the saving mode is changed to the safe saving mode and saving begins again at the beginning of the memory structures 25. It should be appreciated that, according to embodiments of the invention, the saving of additional portions of the

25 memory structures 25 need not return to the beginning.

In the safe saving mode, additional integrity checking is performed on the portions 26A-26N of the memory structures 25 as compared to the normal saving mode. Additionally, if a corrupted portion is encountered while saving in the safe mode, an attempt is made to repair the corrupted portion. If the corrupted portion can

30 be repaired, that portion is saved. If the corrupted portion cannot be repaired, then the

saving of the corrupted portion is skipped. For example, as shown in FIGURE 2 the portion 26B is corrupted and cannot be repaired. Therefore, the saving of the portion 26B is skipped and the portion 26C is saved.

After the portion 26C has been saved, an attempt is then made to save 5 the portion 26D. However, as shown in FIGURE 2, the portion 26D is corrupt. Accordingly, an attempt is made to repair the portion 26D. If the portion 26D cannot be saved, the saving of the portion 26D is skipped and this process continues until the remaining portions have been saved or skipped. According to an embodiment of the 10 invention, the saving of the memory structures 25 may return to the beginning of the memory structures 25 after an unsaveable portion has been encountered and determined to be unrepairable. This is illustrated in FIGURE 2. Returning to the beginning of the memory structures 25 in this manner allows the saving of other portions of the data file 24 that are related to an unsaveable portion to be skipped even though the related portions may not be corrupt.

15 If, during the saving of the memory structures 25, a portion is encountered that is unsaveable and unrepairable, the spreadsheet application program 10 may switch to a third saving mode, called the minimal saving mode. In the minimal saving mode, an attempt is made to save only the user data from the memory structures 25. In particular, with regard to a text document an attempt is made to save only the 20 text of the document. With regard to a spreadsheet document, an attempt is made to save the contents of the spreadsheet cells, including data input by a user, formulas, and formula generated data. In this manner, even if portions of the memory structures 25 are corrupt, some or all of the user data may be recovered and saved. This process is illustrated by the dotted line in FIGURE 2 and would be performed if the portion 26D 25 was determined to be unsaveable and unrepairable. Additional details regarding this process are provided below with respect to FIGURES 3A-3B.

Referring now to FIGURES 3A-3B, the routine 300 will be described illustrating a process performed by the spreadsheet application program 10 for saving the contents of a memory structures 25. When reading the discussion of the routines 30 presented herein, it should be appreciated that the logical operations of various

51028-108

embodiments of the present invention are implemented (1) as a sequence of computer implemented acts or program modules running on a computing system and/or (2) as interconnected machine logic circuits or circuit modules within the computing system. The implementation is a matter of choice dependent on the performance requirements of 5 the computing system implementing the invention. Accordingly, the logical operations illustrated in FIGURES 3A-3B, and making up the embodiments of the present invention described herein are referred to variously as operations, structural devices, acts or modules. It will be recognized by one skilled in the art that these operations, structural devices, acts and modules may be implemented in software, in firmware, in 10 special purpose digital logic, and any combination thereof without deviating from the scope of the present invention as recited within the claims set forth herein.

It should be appreciated that the routine 300 utilizes several variables in its operation. In particular, the “mode” variable keeps track of the current saving mode. This variable may be set to either “safe,” “normal,” or “minimal.” The “skip counter” 15 variable keeps track of the memory structures 25 that should be skipped when the saving of the memory structures 25 returns to the beginning after encountering a corrupt portion. A “number of records to skip” variable describes the current number of sections that should be skipped on the current save attempt. A “current record” variable identifies the current section within the data file being processed. It should be 20 appreciated that more or fewer variables may be utilized to perform the same task. Moreover, it should be appreciated that the routine 300 illustrated in FIGURES 3A and 3B represents but one possible implementation of the invention and that many other implementations will be apparent to those skilled in the art.

The routine 300 begins at either operation 302, 304, or 306. In 25 particular, according to embodiments of the invention, a user interface may be provided that allows a user to select whether a document is saved normally (operation 304), is saved in the safe saving mode (operation 302), or is saved in the minimal saving mode (306). This user interface may be presented to a user when the user requests that a document be saved. Based on the user’s selection within the user interface, the routine 30 300 begins its operation at either operation 302, 304, or 306.

If saving is to begin in the safe saving mode, the routine 300 begins at operation 302, where the mode variable is set to “safe.” The routine 300 then continues to operation 308. If saving is to begin in the normal saving mode, the routine 300 begins at operation 304, where the mode variable is set to “normal.” The routine 300 5 then continues from operation 304 to operation 308. If saving is to begin in the minimal saving mode, the routine begins at operation 306, where the mode variable is set to “minimal.” From operation 306, the routine 300 continues to operation 348, described below.

At operation 308, the skip counter variable is initialized to indicate that 10 no records should be skipped. The routine 300 then continues to operation 310 where the current record is set to the first record in the memory structures. The number of records to skip variable is set equal to the number of records to skip. On the first pass, this sets the number of records to skip equal to zero. From operation 310, the routine 300 continues to operation 312.

15 At operation 312, an attempt is made to save the current record in the current mode. For instance, if the mode variable is equal to “normal,” minimal integrity checking is performed on the section being saved. If the mode variable is equal to “safe,” additional integrity checking is performed. From operation 312, the routine 300 continues to operation 314, where a determination is made as to whether the current 20 record is unsaveable (i.e. either corrupt or missing). If the current record is saveable, the routine 300 branches to operation 316 where a determination is made as to whether more records remain to be saved. If more records exist, the routine 300 branches from operation 316 to operation 318 where the current record variable is set to the next record in the memory structures 25. The routine 300 then continues to operation 312, 25 where the next record is saved. If, at operation 316, it is determined that no additional records remain to be saved, the routine 300 branches to operation 320 where it ends. In this manner, all records are saved in the current mode if no corrupt or missing records exist.

It should be appreciated that, in embodiments of the invention, some 30 integrity checks may be performed at the feature level as opposed to the record level.

To perform such feature level integrity checking, an attempt is made to save all of the records for a particular feature. Then, a determination is made as to whether the data for the feature is valid. If the data is invalid, the skip data structure is updated with the records for the feature to be skipped and another attempt is made to save the file. File-
5 level consistency checks may also be made in a similar manner.

If, at operation 314, it is determined that the current record is unsaveable, the routine 314 continues to operation 322 where a determination is made as to whether the current mode is the normal mode. If the current mode is the normal mode, the routine 300 branches to operation 324, where the skip counter variable is updated
10 indicating that a portion of the memory structures 25 has been identified that may need to be skipped. The routine 300 then continues to operation 324, where the mode variable is set to “safe.” In this manner, the saving mode is switched from normal to safe upon encountering an unsaveable portion of the memory structures 25. The routine 300 then returns back to operation 310, where the processing of the data file returns
15 to the beginning.

If, at operation 322, it is determined that the current saving mode is not the normal mode, the routine 300 continues to operation 328 where a determination is made as to whether the current saving mode is the safe mode. Because only the normal or safe saving modes should be possible values in this portion of the routine 300, the
20 routine branches to operation 330 where an error is returned if the current saving mode is not the safe mode. The routine 300 then continues from operation 330 to operation 320, where it ends. If, however, at operation 328 it is determined that the current mode is the safe mode, the routine 300 continues to operation 332.

At operation 332, an attempt is made to repair the current record. At
25 operation 334, a determination is made as to whether the current record was repairable. If the record was repairable, the routine 300 branches to operation 336, where the current record is saved. At operation 336, the skip counter variable is also updated to indicate that saving of the current record should not be skipped because the record was repairable. From operation 336, the routine 300 branches back to operation 316, where

the remainder of the records of the memory structures 25 are processed in the manner described above.

If, at operation 334, it is determined that the current record could not be repaired, the routine 300 branches to operation 338. At operation 338, a determination 5 is made as to whether the number of records to skip is equal to zero. This would be the case where saving was started in the normal mode and where the first corrupt record was encountered and the record is unrepairable. In this case, the routine 300 branches to operation 340, where the skip counter variable is updated to indicate that the record should be skipped. The routine 300 then returns to operation 310, where processing of 10 the memory structures 25 returns to the beginning in the manner described above.

If, at operation 338, it is determined that the number of records to skip variable is not equal to zero, the routine 300 continues to operation 342, where an attempt is made to skip the saving of the current record. At operation 344 a determination is made as to whether the saving of the current record may be skipped. If 15 saving of the current record can be skipped, the routine 300 branches to operation 346 where the record is flagged in the skip record variable. The routine then continues to operation 316, described above.

If, at operation 344, it is determined that the current record cannot be skipped, the routine 300 continues to operation 306 where the mode variable is set to 20 “minimal.” The routine 300 then continues to operation 348, where an attempt is made to save the memory structures 25 in the minimal mode. As described above, only user data is saved in the minimal mode. Moreover, an attempt is made to save as much of the user data as possible if the user data also is corrupted. The routine 300 then continues to operation 320, where it ends.

25 Based on the foregoing, it should be appreciated that the various embodiments of the invention include a method, system, apparatus, and computer-readable medium for saving the contents of a document stored in a structure in volatile memory to a data file stored on a mass storage device. The above specification, examples and data provide a complete description of the manufacture and use of the 30 composition of the invention. Since many embodiments of the invention can be made

51028-108

without departing from the scope of the invention, the invention resides in the claims hereinafter appended.

51028-108

CLAIMS:

1. A method for saving the contents of a memory structure stored in a volatile memory and having one or more portions to a data file on a mass storage device, the method comprising:

5 attempting to save each portion of the memory structure in a first mode, wherein in the first mode minimal integrity checking is performed on each of the portions;

determining in the first mode by said minimal integrity checking whether a portion of the data file is unsaveable; and

10 in response to determining that a portion is unsaveable, attempting to save the contents of the memory structure in a second mode wherein more extensive integrity checking is performed on each of the portions and wherein saving of each unsaveable portion is skipped wherein while attempting to save the contents of the memory structure in the second mode a determination is made as to whether an unsaveable portion may be repaired, and in response to determining that an unsaveable portion may be repaired, repairing the unsaveable portion
15 and saving the repaired portion to the data file.

2. The method of claim 1, further comprising in response to determining that an unsaveable portion may not be repaired, skipping the saving of the unsaveable portion.

3. The method of claim 2, further comprising:

determining whether the saving of an unsaveable portion may be skipped; and

20 in response to determining that the saving of an unsaveable portion cannot be skipped, attempting to save the contents of the memory structure in a third mode, wherein in the third mode only portions of the memory structure corresponding to user data are saved to the data file.

25 4. The method of claim 3, wherein the user data comprises text data entered by a user.

51028-108

5. The method of claim 3, wherein the user data comprises numerical data entered by a user.

6. A computer-readable storage medium having computer-executable instructions stored thereon which, when executed by a computer, will cause the computer to:

5 provide a first saving mode for saving the contents of a memory structure having one or more portions from a volatile memory to a data file on a mass storage device, wherein minimal integrity checking is performed on each of the portions when saving in the first saving mode;

10 provide a second saving mode for saving the contents of the memory structure to the data file, wherein more extensive integrity checking is performed on each of the portions and wherein saving of each unsaveable portion is skipped;

begin saving the contents of the memory structure in the first saving mode; and

15 determine when operating in the first saving mode by said minimal integrity checking whether a portion of the memory structure is unsaveable and in response to determining that a portion is unsaveable, switching to the second saving mode wherein in the second saving mode a determination is made as to whether an unsaveable portion may be repaired, and in response to determining that an unsaveable portion may be repaired, repairing the unsaveable portion and saving the repaired portion to the data file.

7. The computer-readable storage medium of claim 6, wherein in the second saving mode the saving of the unsaveable portion is skipped in response to determining that an unsaveable portion may not be repaired.

8. The computer-readable storage medium of claim 7 comprising further computer-readable instructions which, when executed by the computer, cause the computer to:

25 provide a third saving mode wherein in the third mode only portions of the memory structure corresponding to user data are saved to the data file;

51028-108

determine while operating in the second saving mode whether the saving of an unsaveable portion may be skipped; and

in response to determining that the saving of an unsaveable portion cannot be skipped, switching to the third saving mode.

5 9. The computer-readable storage medium of claim 8, wherein the user data comprises text data entered by a user.

10. The computer-readable storage medium of claim 9, wherein the user data comprises numerical data entered by a user.

11. A computer-readable medium having computer-executable instructions stored
10 thereon which, when executed by a computer, will cause the computer to:

provide a first saving mode, a second saving mode, and a third saving mode;

begin saving the contents of a memory structure having a plurality of data records in the first saving mode, wherein minimal integrity checking is performed on the at least one data record;

15 determine, by said minimal integrity checking, while saving the contents of the memory structure in the first saving mode whether the at least one of the plurality of data records is unsaveable;

in response to determining in the first saving mode that at least one of the plurality of data records is unsaveable, switch to the second saving mode;

20 attempt to save the contents of the memory structure from its beginning in the second saving mode, wherein in the second saving mode additional integrity checks are performed on the plurality of data records as compared to the first mode;

determine if the at least one unsaveable data record can be repaired;

51028-108

in response to determining that the at least one unsaveable data record can be repaired, repair the at least one unsaveable data record and saving the at least one repaired data record;

in response to determining that the at least one unsaveable data records cannot 5 be repaired, skip the at least one unsaveable and unrepairable data record;

determine while saving the contents of the memory structure in the second saving mode whether the saving of the at least one unsaveable and unrepairable data records cannot be skipped; and

in response to determining that the saving of the at least one unsaveable data 10 record cannot be skipped while saving in the second saving mode, switch to the third saving mode wherein only user data stored in the memory structure is saved.

12. The computer-readable medium of claim 11, wherein one of the plurality of data records may be unsaveable if the record includes an unexpected data value.

13. The computer-readable medium of claim 11, wherein one of the plurality of 15 data records may be unsaveable if the record is missing data.

14. The computer-readable medium of claim 11, wherein one of the plurality of data records may be unsaveable if the one of the plurality of data records includes invalid extensible markup language.

15. The computer-readable medium of claim 11, wherein one of the plurality of 20 data records may be unsaveable if saving of the one of the plurality of data records by an application program causes the application program to crash.

16. The computer-readable medium of claim 11, wherein one of the plurality of data records may be unsaveable if the one of the plurality of data records is corrupt.

17. The computer-readable medium of claim 11, wherein one of the plurality of 25 data records may be unsaveable if the one of the plurality of data records is missing.

51028-108

18. The computer-readable medium of claim 11, wherein the contents of the memory structure comprises text data entered by a user.

19. The computer-readable medium of claim 11, wherein the contents of the memory structure comprises numerical data entered by a user.

5 20. The computer-readable medium of claim 11, wherein the memory structure having the plurality of data records represents an electronic document comprising at least one of a spreadsheet, a presentation, a word processing document, a graphical document, and a computer aided design document.

21. A method for saving the contents of a memory structure comprising a plurality 10 of data records to a data file located on a mass storage device, the method comprising:

providing a first saving mode, a second saving mode, and a third saving mode;

attempting to save the contents of the memory structure to the data file in the first saving mode, wherein minimal integrity checking is performed on the plurality of data records while saving in the first saving mode;

15 determining, by said minimal integrity checking, while saving the memory structure in the first saving mode whether at least one of the plurality of data records is unsaveable;

in response to determining in the first saving mode that at least one of the plurality of data records is unsaveable, switching to the second saving mode;

20 attempting to save the memory structure from its beginning in the second saving mode, wherein in the second saving mode additional integrity checks are performed on the plurality of data records as compared to the first mode;

determining if the at least one unsaveable data record can be repaired;

51028-108

in response to determining that the at least one unsaveable data record can be repaired, repairing the at least one unsaveable data record and saving the at least one repaired data record;

in response to determining that the at least one unsaveable data records cannot 5 be repaired, skipping the at least one unsaveable and unrepairable data record;

determining while saving the memory structure in the second saving mode whether the saving of at least one of the plurality of data records cannot be skipped; and

in response to determining that the saving of at least one of the plurality of data records cannot be skipped while saving in the second saving mode, switching to the third 10 saving mode wherein only the plurality of data records comprising user data stored in the memory structure is saved.

22. The method of claim 21, wherein a data record is unsaveable if it includes an unexpected data value, is missing data, includes invalid extensible markup language, causes an application program to crash when saving the record, is corrupt, or if the record is missing.

15 23. The method of claim 21, wherein the user data stored in the memory structure comprises at least one of text data, numerical data, formulas, and formula generated data.

24. The method of claim 21, further comprising counting the number of data records determined to be unsaveable.

25. The method of claim 21, further comprising counting the number of data 20 records previously determined to be unsaveable that have been repaired and saved.

26. The method of claim 25, further comprising counting the number of unsaveable data records which cannot be repaired.

27. The method of claim 21, prior to the step of attempting to save the contents of the memory structure to the data file in the first saving mode, further comprising:

25 receiving, from a user, a selection of a saving mode; and

51028-108

saving the contents of the memory structure according to the selected saving mode.

28. The method of claim 21 wherein the memory structure comprising the plurality of data records represents an electronic document comprising at least one of a spreadsheet, a presentation, a word processing document, a graphical document, and a computer aided design document.

5 29. The method of claim 21, further comprising:

10 determining, while saving in the third saving mode, whether any of the plurality of data records comprising user data stored in the memory structure are missing or corrupt; and

saving only the plurality of data records comprising user data stored in the memory structure that are not missing or corrupt.

30. A method for saving the contents of a memory structure comprising a plurality of data records to a data file located on a mass storage device, the method comprising:

15 providing a first saving mode, a second saving mode, and a third saving mode; attempting to save the contents of the memory structure to the data file in the first saving mode, wherein minimal integrity checking is performed on the plurality of data records while saving in the first saving mode;

20 determining, by said minimal integrity checking, while saving the memory structure in the first saving mode whether at least one of the plurality of data records is unsaveable, wherein a data record is unsaveable if it includes an unexpected data value, is missing data, includes invalid extensible markup language, causes an application program to crash when saving the record, is corrupt, or if the record is missing;

25 in response to determining in the first saving mode that at least one of the plurality of data records is unsaveable, switching to the second saving mode;

51028-108

attempting to save the memory structure from its beginning in the second saving mode, wherein in the second saving mode additional integrity checks are performed on the plurality of data records as compared to the first mode;

5 determining whether the at least one of the plurality of data records that is unsaveable can be repaired;

in response to determining that the at least one of the plurality of data records that is unsaveable can be repaired:

repairing the at least one of the plurality of data records that is unsaveable; and

saving the at least one of the plurality of data records that has been repaired;

10 in response to determining that the at least one of the plurality of data records that is unsaveable cannot be repaired, skipping the saving of the at least one of the plurality of data records that is unsaveable and unrepairable;

determining while saving the memory structure in the second saving mode whether the saving of at least one of the plurality of data records cannot be skipped; and

15 in response to determining that the saving of at least one of the plurality of data records cannot be skipped while saving in the second saving mode, switching to the third saving mode, wherein the third saving mode comprises:

determining whether any of the plurality of data records comprise user data, wherein user data comprises at least one of text data, numerical data, formulas, and formula generated data;

determining whether any of the plurality of data records comprising user data stored in the memory structure are missing or corrupt; and

saving each of the plurality of data records comprising user data stored in the memory structure that is not missing or corrupt.

51028-108

31. A method for saving the contents of a memory structure stored in a volatile memory and having one or more portions to a data file on a mass storage device, the method comprising:

attempting to save each portion of the memory structure in a first saving mode,
5 wherein in the first mode minimal integrity checking is performed on each of the portions to determine whether a portion of the data file is corrupted;

and

10 in response to determining that a portion is corrupted, attempting to save the contents of the memory structure in a second saving mode wherein more extensive integrity checking is performed on each of the portions to determine as to whether a corrupted portion may be repaired and in response to determining that a corrupted portion may not be repaired, skipping the saving of the corrupted portion.

15 32. The method of claim 31, wherein while attempting to save the contents of the memory structure in the second saving mode a determination is made as to whether a corrupted portion may be repaired, and in response to determining that a corrupted portion may be repaired, repairing the corrupted portion and saving the repaired portion to the data file.

33. The method of claim 32, further comprising:

20 determining whether the saving of a corrupted portion that is not to be repaired may be skipped; and

in response to determining that the saving of a corrupted portion that is not to be repaired cannot be skipped, attempting to save the contents of the memory structure in a third saving mode, wherein in the third saving mode only portions of the memory structure corresponding to user data are saved to the data file.

25 34. The method of claim 33, wherein the user data comprises text data entered by a user.

51028-108

35. The method of claim 33, wherein the user data comprises numerical data entered by a user.

36. A computer-readable medium having computer-executable instructions stored thereon which, when executed by a computer, will cause the computer to:

5 provide a first saving mode for saving the contents of a memory structure having one or more portions from a volatile memory to a data file on a mass storage device, wherein minimal integrity checking is performed on each of the portions to determine whether a portion of the data file is corrupted when saving in the first saving mode;

10 provide a second saving mode for saving the contents of the memory structure to the data file, wherein more extensive integrity checking is performed on each of the portions to determine as to whether a corrupted portion may be repaired, wherein in the second saving mode the saving of the corrupted portion is skipped in response to determining that the corrupted portion may not be repaired,

15 begin saving the contents of the memory structure in the first saving mode; and in response to determining that a portion is corrupted, switching to the second saving mode.

37. The computer-readable medium of claim 36, wherein in the second saving mode a determination is made as to whether a corrupted portion may be repaired, and in response to determining that a corrupted portion may be repaired, repairing the corrupted

20 portion and saving the repaired portion to the data file.

38. The computer-readable medium of claim 37 comprising further computer-readable instructions which, when executed by the computer, cause the computer to:

provide a third saving mode wherein in the third mode only portions of the memory structure corresponding to user data are saved to the data file;

25 determine while operating in the second saving mode whether the saving of a corrupted portion that is not to be repaired may be skipped; and

51028-108

in response to determining that the saving of a corrupted portion that is not to be repaired cannot be skipped, switching to the third saving mode.

39. The computer-readable medium of claim 38, wherein the user data comprises text data entered by a user.

5 40. The computer-readable medium of claim 39, wherein the user data comprises numerical data entered by a user.

41. The computer-readable medium of claim 36, wherein a portion may be corrupted if the portion includes an unexpected data value.

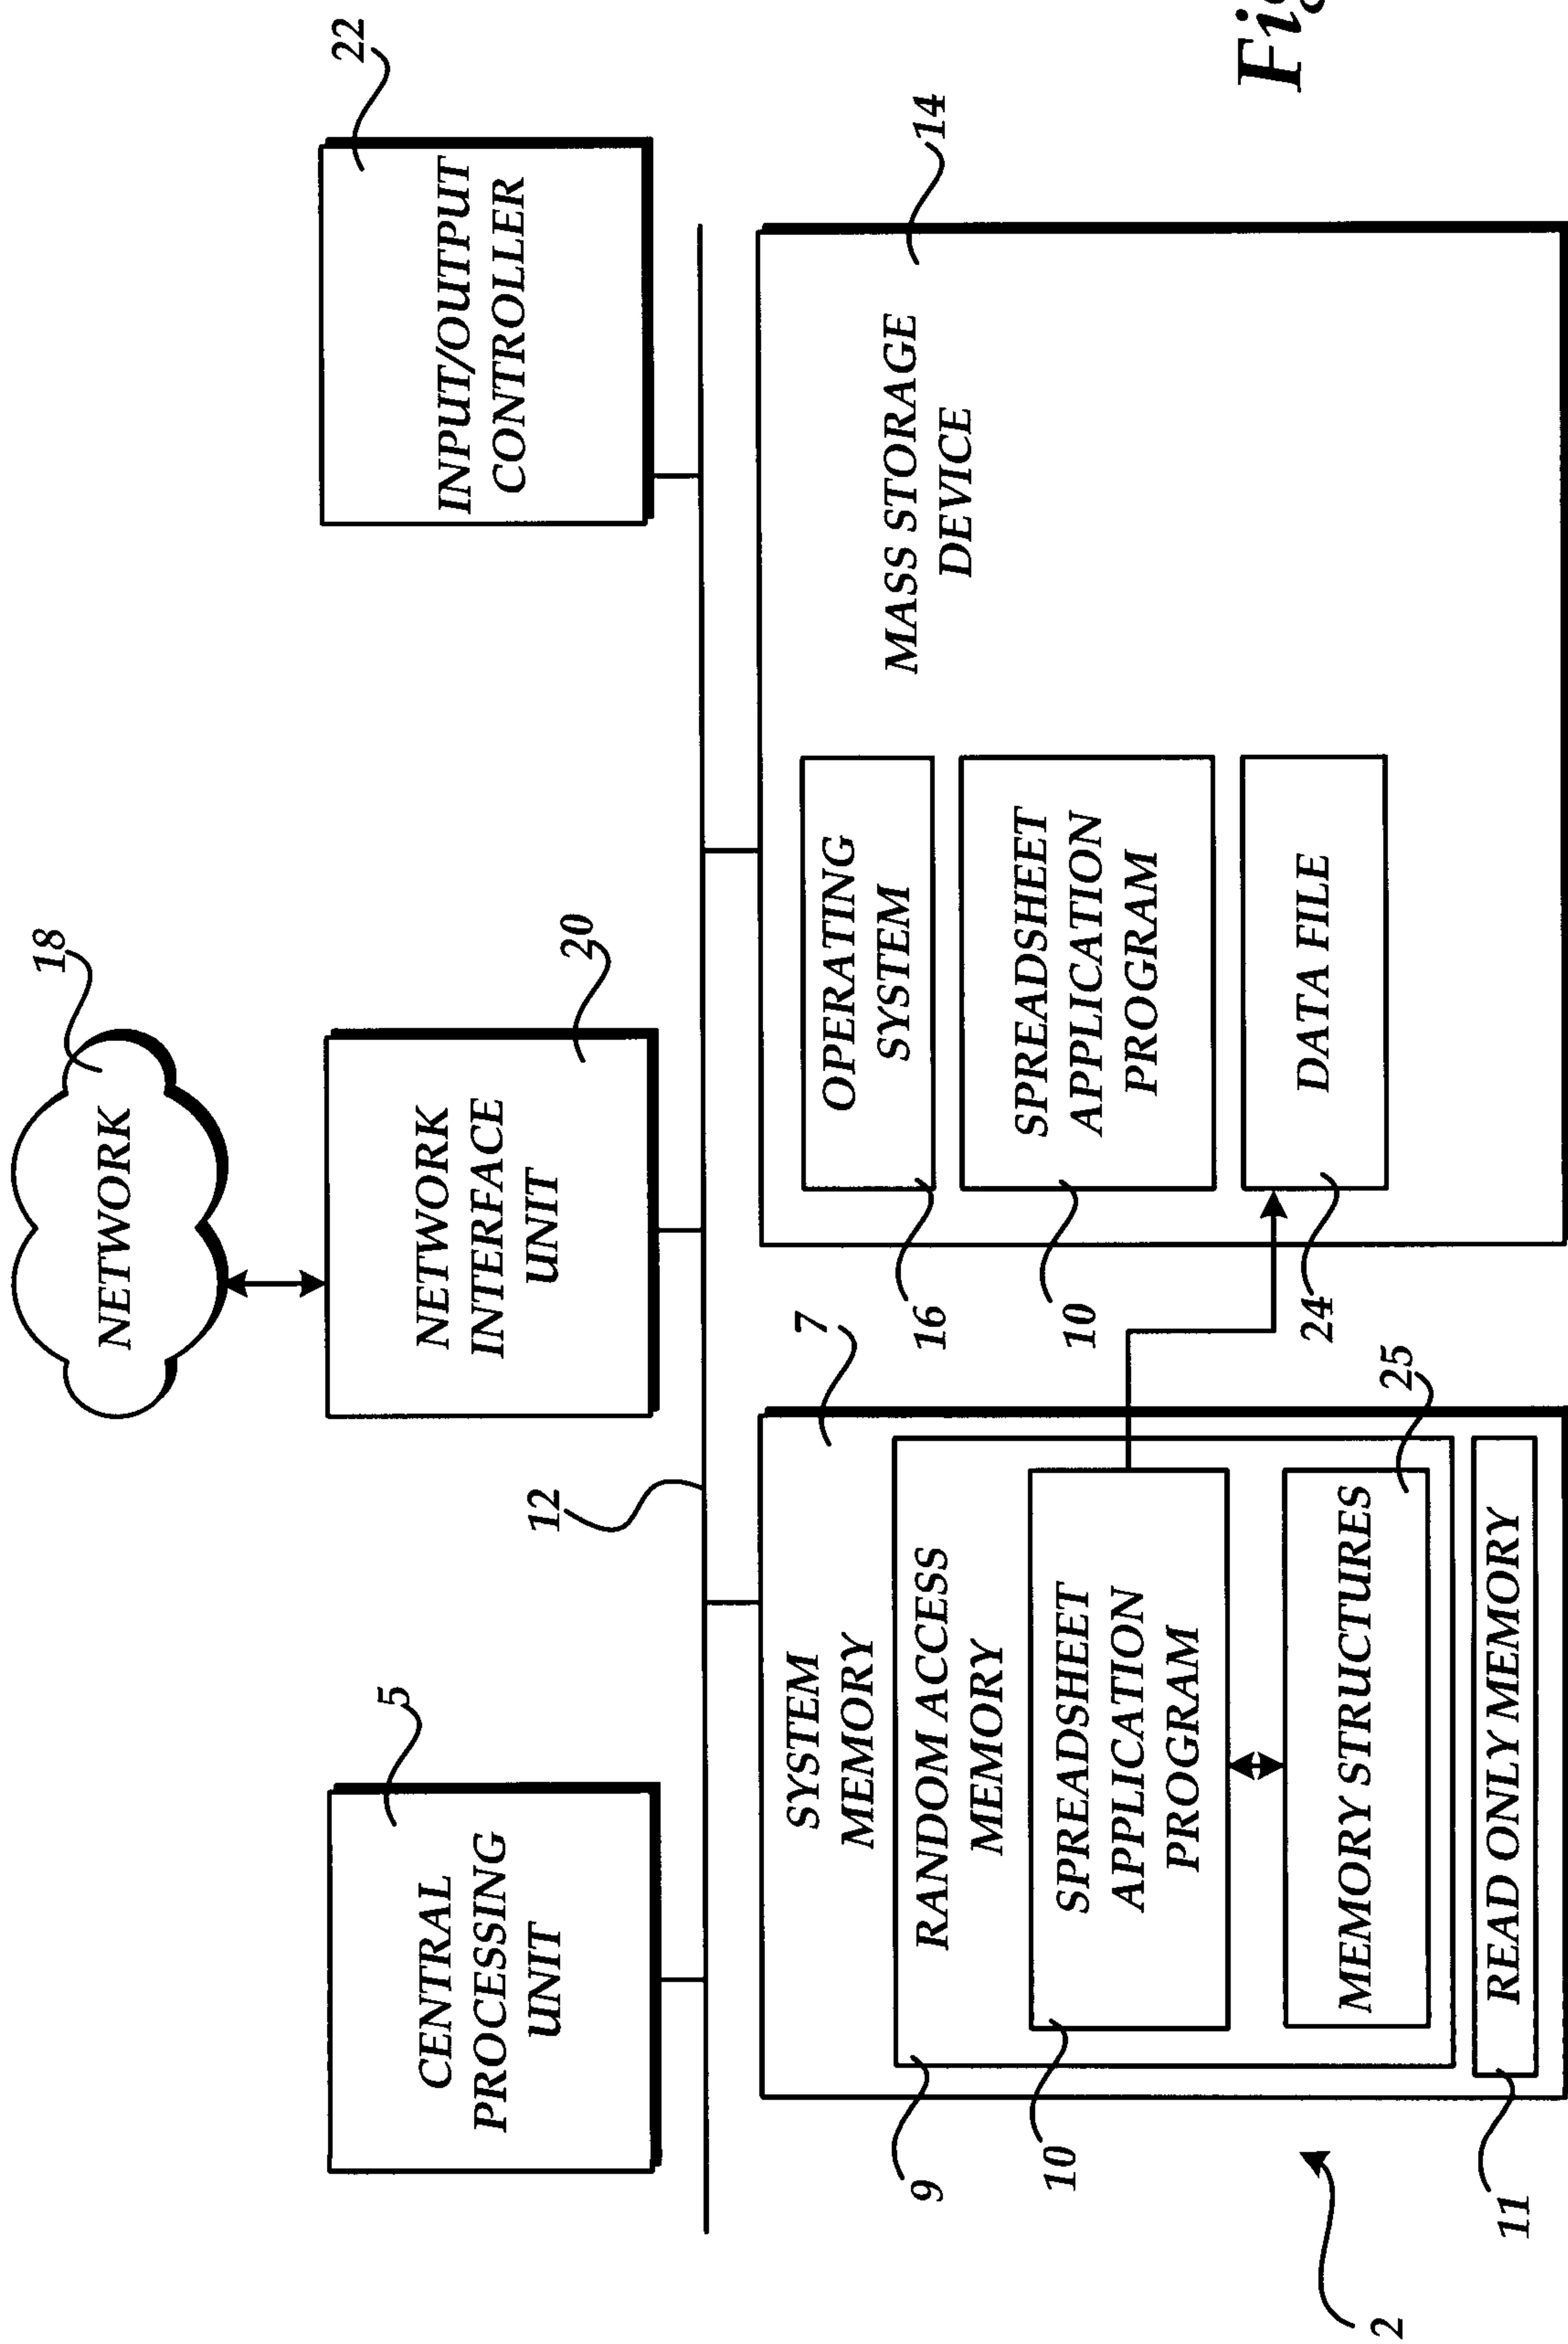

42. The computer-readable medium of claim 41, wherein a portion may further be 10 corrupted if the portion is missing data.

43. The computer-readable medium of claim 42, wherein a portion may further be corrupted if the portion includes invalid extensible markup language.

44. The computer-readable medium of claim 43, wherein a portion may further be corrupted if saving of the portion by an application program causes the application program to 15 crash.

45. The computer-readable medium of claim 44, wherein a portion may further be corrupted if the portion is missing.
