MULTIPLE GROUPINGS IN A PLAYBACK SYSTEM

Abstract: The examples provided herein involve multiple groups in a playback system. A multi-zone scene of a media playback system may comprise at least first and second zones. The first zone may comprise at least two zone players. A user input is detected for generating a multi-zone scene and in response to detecting the trigger, storing a multi-zone scene configuration of a plurality of zone groups. The multi-zone scene configuration of the plurality of zone groups may include an indication of the plurality of zone groups that belong to the multi-zone group scene; and stored configuration data for the plurality of zone groups including the zone players currently associated with the plurality of zone groups. The configuration data is transmitted to at least a first zone player in the first zone group for subsequent instantiation of the multi-zone group scene.

MULTIPLE GROUPINGS IN A PLAYBACK SYSTEM

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of priority under PCT Article 8 to United States Patent Application Serial No. 14/737,199 filed on June 11, 2015, and entitled "Multiple Groupings in a Playback System", the contents of which are herein incorporated in its entirety.

FIELD OF THE DISCLOSURE

[1] The disclosure is related to consumer goods and, more particularly, to methods, systems, products, features, services, and other elements directed to media playback or some aspect thereof. Multi-zone group scenes, as disclosed herein, build upon the concepts disclosed by Lambourne et al. in U.S. Patent No. 8,483,853 which is hereby incorporated herein by reference in its entirety.

BACKGROUND

[2] Options for accessing and listening to digital audio in an out-loud setting were limited until in 2003, when SONOS, Inc., filed for one of its first patent applications, entitled "Method for Synchronizing Audio Playback between Multiple Networked Devices," and began offering a media playback system for sale in 2005. The Sonos Wireless HiFi System enables people to experience music from many sources via one or more networked playback devices. Through a software control application installed on a smartphone, tablet, or computer, one can play what he or she wants in any room that has a networked playback device. Additionally, using the controller, for example, different songs can be streamed to each room with a playback device, rooms can be grouped together for synchronous playback, or the same song can be heard in all rooms synchronously.

[3] Given the ever growing interest in digital media, there continues to be a need to develop consumer-accessible technologies to further enhance the listening experience.

BRIEF DESCRIPTION OF THE DRAWINGS

[4] Features, aspects, and advantages of the presently disclosed technology may be better understood with regard to the following description, appended claims, and accompanying drawings where:
[5] Figure 1 shows an example media playback system configuration in which certain embodiments may be practiced;
[6] Figure 2 shows a functional block diagram of an example playback device;
Figure 3 shows a functional block diagram of an example control device;

Figure 4 shows an example controller interface;

Figure 5A shows an example user interface for creating a multi-zone group scene;

Figure 5B shows an example user interface for creating a multi-zone group scene;

Figure 6 shows an example data structure including configuration data for multi-zone group scenes;

Figure 7 shows an example user interface to instantiate a created multi-zone group scene;

Figure 8 shows an example flow diagram to create a multi-zone group scene at a controller;

Figure 9 shows an example flow diagram to store a multi-zone group scene at a playback device;

Figure 10 shows an example flow diagram to instantiate a multi-zone group scene at a controller;

Figure 11 shows an example flow diagram to instantiate a multi-zone group scene at a playback device;

Figure 12 shows an example flow diagram to create a multi-zone group scene at a controller;

Figure 13 shows an example diagram of data flow in a media playback system in accordance with methods disclosed herein.

The drawings are for the purpose of illustrating example embodiments, but it is understood that the inventions are not limited to the arrangements and instrumentality shown in the drawings.

DETAILED DESCRIPTION

I. Overview

A media playback system provides media playback through one or more areas of a household and/or other location. One or more zones associated with the media playback system can be configured in a zone scene or zone theme to output media content as a group, for example. According to a zone scene, one or more zones in the media playback system can be linked, grouped, and/or otherwise configured to play back media according to certain attributes and/or other configuration parameters. Zone scene configuration information can be stored at one or more of a controller, playback device, network attached storage device, etc.

In one embodiment, a controller of a media playback system provides an interface to
create multi-zone group scenes including zone players (also referred to herein as playback
devices or media playback devices, etc.) and/or zone groups and associated configuration
information. In certain examples, a multi-zone group scene can be stored locally at the control
device and transmitted to at least one zone player of at least one zone group in the media
playback system. In other examples, a multi-zone group scene can be stored at a zone player, an
external server, network attached storage device, etc.

[22] For example, a controller is used to create a "household" multi-zone group scene to
play jazz music. The zone groups included in the "household" multi-zone group scene include a
kitchen, patio, and living room zone group. One or more of the zone groups include multiple
zone players. When the "household" multi-zone group scene is created on the controller, the
controller stores configuration data for the "household" multi-zone group scene locally and
transmits the configuration data to a first zone player in the kitchen zone group.

[23] The multi-zone group scene provides a hierarchy of multiple zones forming a multi-
zone group scene, and one or more of the constituent zones includes a plurality of zone players
organized according to that zone. By invoking the multi-zone group scene, one or more zone
groups and their constituent zone players are triggered to instantiate the specified configuration.
Thus, the multi-zone group scene configuration can specify configuration (e.g., grouping,
content, equalization setting, etc.) for one or more zone groups as well as one or more zone
players within each of the one or more zone groups.

[24] In another embodiment, the controller provides an interface to instantiate created and/or
stored multi-zone group scenes. The multi-zone group scene is instantiated by transmitting a
command from the controller to at least one zone player of one zone group in the multi-zone
group scene.

[25] For example, the controller interface is used to recall and/or instantiate the "household"
multi-zone group scene to play jazz music (e.g., by selecting the "household" multi-zone group
scene). When the "household" multi-zone group scene is selected on the controller, the controller
transmits an instruction to instantiate the "household" multi-zone group scene to the first zone
player in the kitchen zone group. When the instruction to instantiate the "household" multi-zone
group scene is detected by the first zone player in the kitchen zone group, the first zone player
operates under the configuration data for the "household" multi-zone group scene. The first zone
player in the kitchen zone group also relays (e.g., transmits) the instructions to instantiate the
"household" multi-zone group scene to other zone players in the patio and living room zone
groups. The other players in the patio and living room zone groups operate under the
configuration data for the "household" multi-zone group scene in response to the other player's
[26] In another embodiment, rather than routing communications through the first zone player, the controller instead communicates with each zone player in the multi-zone group scene to instantiate the multi-zone group scene. Rather than relying on a first zone player to relay communications from the controller to other participating zone players, the controller can directly communicate with member zone players to instantiate the multi-zone group scene.

[27] In another embodiment, a playback device (e.g., a zone player) stores and/or transmits the multi-zone group scene configuration data to other zone groups in the multi-zone group scene. The playback device likewise determines that the multi-zone group scene is to be instantiated, transmits the command to other zone groups in the multi-zone group scene, and operates according to the configuration data for the multi-zone group scene.

[28] For example, in the first embodiment, the first zone player in the kitchen zone group relays (e.g., transmits) the configuration data to other zone players in the patio and living room zone groups. In the second embodiment, during instantiation of the multi-zone group scene, the first zone player in the kitchen zone group relays (e.g., transmits) instructions to instantiate the "household" multi-zone group scene to other zone players in the patio and living room zone groups. The other players in the patio and living room zone groups operate under the configuration data for the "household" multi-zone group scene in response to the other player's detection of the instructions to instantiate.

[29] As indicated above, the examples provided herein involve multiple groups in a playback system. In one aspect, a method is provided. The method involves facilitating, via a user interface of a controller, storage of a configuration of multiple zone groups as a multi-zone scene of a media playback system, the media playback system including at least a first zone group including at least two zone players and a second zone group, the user interface of the controller presenting at least an indication of (1) the first zone group, (2) the second zone group, and (3) a multi-zone group scene creation command. The method involves generating, via the controller based on a detected triggering of the multi-zone group scene creation command, a multi-zone scene configuration including stored configuration data for the first zone group and the second zone group to instantiate the multi-zone scene based on identified parameters associated with the captured configuration of the multiple zone groups of the media playback system, the parameters including (1) zone players currently associated with the first zone group and the second zone group, and (2) an indication that the first zone group and the second zone group belong to the multi-zone group scene, and transmitting the configuration data to at least a first zone player in the first zone group for subsequent instantiation of the multi-zone group.
scene. In some examples, the controller may save the multi-zone scene configuration data. In other examples, the multi-zone scene configuration data may be stored elsewhere (e.g., a zone player, other external storage, etc.), and the controller send an instruction or command to one or more zone players involved in the multi-zone group scene.

[30] In another aspect, a device or apparatus is provided. The apparatus may include a controller, zone player, etc. The apparatus includes a processor, and memory having stored thereon instructions executable by the processor to cause the device to perform functions. The functions include facilitating, via a user interface of the apparatus, storage of a configuration of multiple zone groups as a multi-zone scene of a media playback system, the media playback system including at least a first zone group including at least two zone players and a second zone group, the user interface presenting at least an indication of (1) the first zone group, (2) the second zone group, and (3) a multi-zone group scene creation command. The functions include generating, based on a detected triggering of the multi-zone group scene creation command, a multi-zone scene configuration including stored configuration data for the first zone group and the second zone group to instantiate the multi-zone scene based on identified parameters associated with the captured configuration of the multiple zone groups of the media playback system, the parameters including (1) zone players currently associated with the first zone group and the second zone group, and (2) an indication that the first zone group and the second zone group belong to the multi-zone group scene, and transmitting the configuration data to at least a first zone player in the first zone group for subsequent instantiation of the multi-zone group scene.

[31] In yet another aspect, a non-transitory computer readable memory is provided. The non-transitory computer readable memory has stored thereon instructions executable by a computing device to cause the computing device to perform functions. The functions include facilitating, via a user interface, storage of a configuration of multiple zone groups as a multi-zone scene of a media playback system, the media playback system including at least a first zone group including at least two zone players and a second zone group, the user interface presenting at least an indication of (1) the first zone group, (2) the second zone group, and (3) a multi-zone group scene creation command. The functions include generating, based on a detected triggering of the multi-zone group scene creation command, a multi-zone scene configuration including stored configuration data for the first zone group and the second zone group to instantiate the multi-zone scene based on identified parameters associated with the captured configuration of the multiple zone groups of the media playback system, the parameters including (1) zone players currently associated with the first zone group and the second zone group, and (2) an
indication that the first zone group and the second zone group belong to the multi-zone group scene, and transmitting the configuration data to at least a first zone player in the first zone group for subsequent instantiation of the multi-zone group scene.

[32] While some examples described herein may refer to functions performed by given actors such as "users" and/or other entities, it should be understood that this is for purposes of explanation only. The claims should not be interpreted to require action by any such example actor unless explicitly required by the language of the claims themselves. It will be understood by one of ordinary skill in the art that this disclosure includes numerous other embodiments.

II. Example Operating Environment

[33] Figure 1 shows an example configuration of a media playback system 100 in which one or more embodiments disclosed herein may be practiced or implemented. The media playback system 100 as shown is associated with an example home environment having several rooms and spaces, such as for example, a master bedroom, an office, a dining room, and a living room. As shown in the example of Figure 1, the media playback system 100 includes playback devices 102-124, control devices 126 and 128, and a wired or wireless network router 130.

[34] Further discussions relating to the different components of the example media playback system 100 and how the different components may interact to provide a user with a media experience may be found in the following sections. While discussions herein may generally refer to the example media playback system 100, technologies described herein are not limited to applications within, among other things, the home environment as shown in Figure 1. For instance, the technologies described herein may be useful in environments where multi-zone audio may be desired, such as, for example, a commercial setting like a restaurant, mall or airport, a vehicle like a sports utility vehicle (SUV), bus or car, a ship or boat, an airplane, and so on.

a. Example Playback Devices

[35] Figure 2 shows a functional block diagram of an example playback device 200 that may be configured to be one or more of the playback devices 102-124 of the media playback system 100 of Figure 1. The playback device 200 may include a processor 202, software components 204, memory 206, audio processing components 208, audio amplifier(s) 210, speaker(s) 212, and a network interface 214 including wireless interface(s) 216 and wired interface(s) 218. In one case, the playback device 200 may not include the speaker(s) 212, but rather a speaker interface for connecting the playback device 200 to external speakers. In another case, the playback device 200 may include neither the speaker(s) 212 nor the audio amplifier(s) 210, but rather an audio interface for connecting the playback device 200 to an external audio amplifier or audio-visual device.
In one example, the processor 202 may be a clock-driven computing component configured to process input data according to instructions stored in the memory 206. The memory 206 may be a tangible computer-readable medium configured to store instructions executable by the processor 202. For instance, the memory 206 may be data storage that can be loaded with one or more of the software components 204 executable by the processor 202 to achieve certain functions. In one example, the functions may involve the playback device 200 retrieving audio data from an audio source or another playback device. In another example, the functions may involve the playback device 200 sending audio data to another device or playback device on a network. In yet another example, the functions may involve pairing of the playback device 200 with one or more playback devices to create a multi-channel audio environment.

Certain functions may involve the playback device 200 synchronizing playback of audio content with one or more other playback devices. During synchronous playback, a listener will preferably not be able to perceive time-delay differences between playback of the audio content by the playback device 200 and the one or more other playback devices. U.S. Patent No. 8,234,395 entitled, "System and method for synchronizing operations among a plurality of independently clocked digital data processing devices," which is hereby incorporated by reference, provides in more detail some examples for audio playback synchronization among playback devices.

The memory 206 may further be configured to store data associated with the playback device 200, such as one or more zones and/or zone groups the playback device 200 is a part of, audio sources accessible by the playback device 200, or a playback queue that the playback device 200 (or some other playback device) may be associated with. The data may be stored as one or more state variables that are periodically updated and used to describe the state of the playback device 200. The memory 206 may also include the data associated with the state of the other devices of the media system, and shared from time to time among the devices so that one or more of the devices have the most recent data associated with the system. Other embodiments are also possible.

The audio processing components 208 may include one or more digital-to-analog converters (DAC), an audio preprocessing component, an audio enhancement component or a digital signal processor (DSP), and so on. In one embodiment, one or more of the audio processing components 208 may be a subcomponent of the processor 202. In one example, audio content may be processed and/or intentionally altered by the audio processing components 208 to produce audio signals. The produced audio signals may then be provided to the audio
amplifier(s) 210 for amplification and playback through speaker(s) 212. Particularly, the audio amplifier(s) 210 may include devices configured to amplify audio signals to a level for driving one or more of the speakers 212. The speaker(s) 212 may include an individual transducer (e.g., a "driver") or a complete speaker system involving an enclosure with one or more drivers. A particular driver of the speaker(s) 212 may include, for example, a subwoofer (e.g., for low frequencies), a mid-range driver (e.g., for middle frequencies), and/or a tweeter (e.g., for high frequencies). In some cases, each transducer in the one or more speakers 212 may be driven by an individual corresponding audio amplifier of the audio amplifier(s) 210. In addition to producing analog signals for playback by the playback device 200, the audio processing components 208 may be configured to process audio content to be sent to one or more other playback devices for playback.

Audio content to be processed and/or played back by the playback device 200 may be received from an external source, such as via an audio line-in input connection (e.g., an auto-detecting 3.5mm audio line-in connection) or the network interface 214.

The network interface 214 may be configured to facilitate a data flow between the playback device 200 and one or more other devices on a data network. As such, the playback device 200 may be configured to receive audio content over the data network from one or more other playback devices in communication with the playback device 200, network devices within a local area network, or audio content sources over a wide area network such as the Internet. In one example, the audio content and other signals transmitted and received by the playback device 200 may be transmitted in the form of digital packet data containing an Internet Protocol (IP)-based source address and IP-based destination addresses. In such a case, the network interface 214 may be configured to parse the digital packet data such that the data destined for the playback device 200 is properly received and processed by the playback device 200.

As shown, the network interface 214 may include wireless interface(s) 216 and wired interface(s) 218. The wireless interface(s) 216 may provide network interface functions for the playback device 200 to wirelessly communicate with other devices (e.g., other playback device(s), speaker(s), receiver(s), network device(s), control device(s) within a data network the playback device 200 is associated with) in accordance with a communication protocol (e.g., any wireless standard including IEEE 802.11a, 802.11b, 802.11g, 802.11n, 802.11ac, 802.15, 4G mobile communication standard, and so on). The wired interface(s) 218 may provide network interface functions for the playback device 200 to communicate over a wired connection with other devices in accordance with a communication protocol (e.g., IEEE 802.3). While the network interface 214 shown in Figure 2 includes both wireless interface(s) 216 and wired
interface(s) 218, the network interface 214 may in some embodiments include only wireless interface(s) or only wired interface(s).

[43] In one example, the playback device 200 and one other playback device may be paired to play two separate audio components of audio content. For instance, playback device 200 may be configured to play a left channel audio component, while the other playback device may be configured to play a right channel audio component, thereby producing or enhancing a stereo effect of the audio content. The paired playback devices (also referred to as "bonded playback devices") may further play audio content in synchrony with other playback devices.

[44] In another example, the playback device 200 may be sonically consolidated with one or more other playback devices to form a single, consolidated playback device. A consolidated playback device may be configured to process and reproduce sound differently than an unconsolidated playback device or playback devices that are paired, because a consolidated playback device may have additional speaker drivers through which audio content may be rendered. For instance, if the playback device 200 is a playback device designed to render low frequency range audio content (i.e. a subwoofer), the playback device 200 may be consolidated with a playback device designed to render full frequency range audio content. In such a case, the full frequency range playback device, when consolidated with the low frequency playback device 200, may be configured to render only the mid and high frequency components of audio content, while the low frequency range playback device 200 renders the low frequency component of the audio content. The consolidated playback device may further be paired with a single playback device or yet another consolidated playback device.

[45] By way of illustration, SONOS, Inc. presently offers (or has offered) for sale certain playback devices including a "PLAY:1," "PLAY:3," "PLAY:5," "PLAYBAR," "CONNECT: AMP," "CONNECT," and "SUB." Any other past, present, and/or future playback devices may additionally or alternatively be used to implement the playback devices of example embodiments disclosed herein. Additionally, it is understood that a playback device is not limited to the example illustrated in Figure 2 or to the SONOS product offerings. For example, a playback device may include a wired or wireless headphone. In another example, a playback device may include or interact with a docking station for personal mobile media playback devices. In yet another example, a playback device may be integral to another device or component such as a television, a lighting fixture, or some other device for indoor or outdoor use.

b. Example Playback Zone Configurations

[46] Referring back to the media playback system 100 of Figure 1, the
environment may have one or more playback zones, each with one or more playback devices. The media playback system 100 may be established with one or more playback zones, after which one or more zones may be added, or removed to arrive at the example configuration shown in Figure 1. Each zone may be given a name according to a different room or space such as an office, bathroom, master bedroom, bedroom, kitchen, dining room, living room, and/or balcony. In one case, a single playback zone may include multiple rooms or spaces. In another case, a single room or space may include multiple playback zones.

[47] As shown in Figure 1, the balcony, dining room, kitchen, bathroom, office, and bedroom zones each have one playback device, while the living room and master bedroom zones each have multiple playback devices. In the living room zone, playback devices 104, 106, 108, and 110 may be configured to play audio content in synchrony as individual playback devices, as one or more bonded playback devices, as one or more consolidated playback devices, or any combination thereof. Similarly, in the case of the master bedroom, playback devices 122 and 124 may be configured to play audio content in synchrony as individual playback devices, as a bonded playback device, or as a consolidated playback device.

[48] In one example, one or more playback zones in the environment of Figure 1 may each be playing different audio content. For instance, the user may be grilling in the balcony zone and listening to hip hop music being played by the playback device 102 while another user may be preparing food in the kitchen zone and listening to classical music being played by the playback device 114. In another example, a playback zone may play the same audio content in synchrony with another playback zone. For instance, the user may be in the office zone where the playback device 118 is playing the same rock music that is being played by playback device 102 in the balcony zone. In such a case, playback devices 102 and 118 may be playing the rock music in synchrony such that the user may seamlessly (or at least substantially seamlessly) enjoy the audio content that is being played out-loud while moving between different playback zones. Synchronization among playback zones may be achieved in a manner similar to that of synchronization among playback devices, as described in previously referenced U.S. Patent No. 8,234,395.

[49] As suggested above, the zone configurations of the media playback system 100 may be dynamically modified, and in some embodiments, the media playback system 100 supports numerous configurations. For instance, if a user physically moves one or more playback devices to or from a zone, the media playback system 100 may be reconfigured to accommodate the change(s). For instance, if the user physically moves the playback device 102 from the balcony zone to the office zone, the office zone may now include both the playback device 118 and
the playback device 102. The playback device 102 may be paired or grouped with the office zone
and/or renamed if so desired via a control device such as the control devices 126 and 128. On the
other hand, if the one or more playback devices are moved to a particular area in the home
environment that is not already a playback zone, a new playback zone may be created for the
particular area.

Further, different playback zones of the media playback system 100 may be
dynamically combined into zone groups or split up into individual playback zones. For instance,
the dining room zone and the kitchen zone 114 may be combined into a zone group for a dinner
party such that playback devices 112 and 114 may render audio content in synchrony. On the
other hand, the living room zone may be split into a television zone including playback device
104, and a listening zone including playback devices 106, 108, and 110, if the user wishes to
listen to music in the living room space while another user wishes to watch television.

c. Example Control Devices

Figure 3 shows a functional block diagram of an example control device 300 that may
be configured to be one or both of the control devices 126 and 128 of the media playback system
100. As shown, the control device 300 may include a processor 302, memory 304, a network
interface 306, and a user interface 308. In one example, the control device 300 may be a
dedicated controller for the media playback system 100. In another example, the control device
300 may be a network device on which media playback system controller application software
may be installed, such as for example, an iPhone™, iPad™ or any other smart phone, tablet or
network device (e.g., a networked computer such as a PC or Mac™).

The processor 302 may be configured to perform functions relevant to facilitating user
access, control, and configuration of the media playback system 100. The memory 304 may be
configured to store instructions executable by the processor 302 to perform those functions. The
memory 304 may also be configured to store the media playback system controller application
software and other data associated with the media playback system 100 and the user.

In one example, the network interface 306 may be based on an industry standard (e.g.,
infrared, radio, wired standards including IEEE 802.3, wireless standards including IEEE
802.11a, 802.11b, 802.11g, 802.11n, 802.11ac, 802.15, 4G mobile communication standard, and
so on). The network interface 306 may provide a means for the control device 300 to
communicate with other devices in the media playback system 100. In one example, data and
information (e.g., such as a state variable) may be communicated between control device 300
and other devices via the network interface 306. For instance, playback zone and zone group
configurations in the media playback system 100 may be received by the control device 300
from a playback device or another network device, or transmitted by the control device 300 to another playback device or network device via the network interface 306. In some cases, the other network device may be another control device.

Playback device control commands such as volume control and audio playback control may also be communicated from the control device 300 to a playback device via the network interface 306. As suggested above, changes to configurations of the media playback system 100 may also be performed by a user using the control device 300. The configuration changes may include adding/removing one or more playback devices to/from a zone, adding/removing one or more zones to/from a zone group, forming a bonded or consolidated player, separating one or more playback devices from a bonded or consolidated player, among others. Accordingly, the control device 300 may sometimes be referred to as a controller, whether the control device 300 is a dedicated controller or a network device on which media playback system controller application software is installed.

The user interface 308 of the control device 300 may be configured to facilitate user access and control of the media playback system 100, by providing a controller interface such as the controller interface 400 shown in Figure 4. The controller interface 400 includes a playback control region 410, a playback zone region 420, a playback status region 430, a playback queue region 440, and an audio content sources region 450. The user interface 400 as shown is just one example of a user interface that may be provided on a network device such as the control device 300 of Figure 3 (and/or the control devices 126 and 128 of Figure 1) and accessed by users to control a media playback system such as the media playback system 100. Other user interfaces of varying formats, styles, and interactive sequences may alternatively be implemented on one or more network devices to provide comparable control access to a media playback system.

The playback control region 410 may include selectable (e.g., by way of touch or by using a cursor) icons to cause playback devices in a selected playback zone or zone group to play or pause, fast forward, rewind, skip to next, skip to previous, enter/exit shuffle mode, enter/exit repeat mode, enter/exit cross fade mode. The playback control region 410 may also include selectable icons to modify equalization settings, and playback volume, among other possibilities.

The playback zone region 420 may include representations of playback zones within the media playback system 100. In some embodiments, the graphical representations of playback zones may be selectable to bring up additional selectable icons to manage or configure the playback zones in the media playback system, such as a creation of bonded zones, creation of zone groups, separation of zone groups, and renaming of zone groups, among other possibilities.

For example, as shown, a "group" icon may be provided within each of the
graphical representations of playback zones. The "group" icon provided within a graphical representation of a particular zone may be selectable to bring up options to select one or more other zones in the media playback system to be grouped with the particular zone. Once grouped, playback devices in the zones that have been grouped with the particular zone will be configured to play audio content in synchrony with the playback device(s) in the particular zone. Analogously, a "group" icon may be provided within a graphical representation of a zone group. In this case, the "group" icon may be selectable to bring up options to deselect one or more zones in the zone group to be removed from the zone group. Other interactions and implementations for grouping and ungrouping zones via a user interface such as the user interface 400 are also possible. The representations of playback zones in the playback zone region 420 may be dynamically updated as playback zone or zone group configurations are modified.

[59] The playback status region 430 may include graphical representations of audio content that is presently being played, previously played, or scheduled to play next in the selected playback zone or zone group. The selected playback zone or zone group may be visually distinguished on the user interface, such as within the playback zone region 420 and/or the playback status region 430. The graphical representations may include track title, artist name, album name, album year, track length, and other relevant information that may be useful for the user to know when controlling the media playback system via the user interface 400.

[60] The playback queue region 440 may include graphical representations of audio content in a playback queue associated with the selected playback zone or zone group. In some embodiments, each playback zone or zone group may be associated with a playback queue containing information corresponding to zero or more audio items for playback by the playback zone or zone group. For instance, each audio item in the playback queue may comprise a uniform resource identifier (URI), a uniform resource locator (URL) or some other identifier that may be used by a playback device in the playback zone or zone group to find and/or retrieve the audio item from a local audio content source or a networked audio content source, possibly for playback by the playback device.

[61] In one example, a playlist may be added to a playback queue, in which case information corresponding to each audio item in the playlist may be added to the playback queue. In another example, audio items in a playback queue may be saved as a playlist. In a further example, a playback queue may be empty, or populated but "not in use" when the playback zone or zone group is playing continuously streaming audio content, such as Internet radio that may continue to play until otherwise stopped, rather than discrete audio items that have playback durations. In an alternative embodiment, a playback queue can include
Internet radio and/or other streaming audio content items and be "in use" when the playback
zone or zone group is playing those items. Other examples are also possible.

[62] When playback zones or zone groups are "grouped" or "ungrouped," playback queues
associated with the affected playback zones or zone groups may be cleared or re-associated. For
example, if a first playback zone including a first playback queue is grouped with a second
playback zone including a second playback queue, the established zone group may have an
associated playback queue that is initially empty, that contains audio items from the first
playback queue (such as if the second playback zone was added to the first playback zone), that
contains audio items from the second playback queue (such as if the first playback zone was
added to the second playback zone), or a combination of audio items from both the first and
second playback queues. Subsequently, if the established zone group is ungrouped, the resulting
first playback zone may be re-associated with the previous first playback queue, or be associated
with a new playback queue that is empty or contains audio items from the playback queue
associated with the established zone group before the established zone group was ungrouped.
Similarly, the resulting second playback zone may be re-associated with the previous second
playback queue, or be associated with a new playback queue that is empty, or contains audio
items from the playback queue associated with the established zone group before the established
zone group was ungrouped. Other examples are also possible.

[63] Referring back to the user interface 400 of Figure 4, the graphical representations of
audio content in the playback queue region 440 may include track titles, artist names, track
lengths, and other relevant information associated with the audio content in the playback queue.
In one example, graphical representations of audio content may be selectable to bring up
additional selectable icons to manage and/or manipulate the playback queue and/or audio content
represented in the playback queue. For instance, a represented audio content may be removed
from the playback queue, moved to a different position within the playback queue, or selected to
be played immediately, or after any currently playing audio content, among other possibilities. A
playback queue associated with a playback zone or zone group may be stored in a memory on
one or more playback devices in the playback zone or zone group, on a playback device that is
not in the playback zone or zone group, and/or some other designated device.

[64] The audio content sources region 450 may include graphical representations of
selectable audio content sources from which audio content may be retrieved and played by the
selected playback zone or zone group. Discussions pertaining to audio content sources may be
found in the following section.
d. **Example Audio Content Sources**

[65] As indicated previously, one or more playback devices in a zone or zone group may be configured to retrieve for playback audio content (e.g. according to a corresponding URI or URL for the audio content) from a variety of available audio content sources. In one example, audio content may be retrieved by a playback device directly from a corresponding audio content source (e.g., a line-in connection). In another example, audio content may be provided to a playback device over a network via one or more other playback devices or network devices.

[66] Example audio content sources may include a memory of one or more playback devices in a media playback system such as the media playback system 100 of Figure 1, local music libraries on one or more network devices (such as a control device, a network-enabled personal computer, or a networked-attached storage (NAS), for example), streaming audio services providing audio content via the Internet (e.g., the cloud), or audio sources connected to the media playback system via a line-in input connection on a playback device or network devise, among other possibilities.

[67] In some embodiments, audio content sources may be regularly added or removed from a media playback system such as the media playback system 100 of Figure 1. In one example, an indexing of audio items may be performed whenever one or more audio content sources are added, removed or updated. Indexing of audio items may involve scanning for identifiable audio items in all folders/directory shared over a network accessible by playback devices in the media playback system, and generating or updating an audio content database containing metadata (e.g., title, artist, album, track length, among others) and other associated information, such as a URI or URL for each identifiable audio item found. Other examples for managing and maintaining audio content sources may also be possible.

[68] The above discussions relating to playback devices, controller devices, playback zone configurations, and media content sources provide only some examples of operating environments within which functions and methods described below may be implemented. Other operating environments and configurations of media playback systems, playback devices, and network devices not explicitly described herein may also be applicable and suitable for implementation of the functions and methods.

**III. Multiple groupings in a Playback System**

[69] As discussed above, embodiments described herein may involve storing a configuration of multiple zone groups as a multi-zone group scene of the media playback system. As used herein, multi-zone group scene and multi zone scene are used interchangeably. For example, a media playback system may include a large number of zone players scattered throughout a
house. Further, each zone player may be further configured into a zone group to provide unique collections of zone players and playback of varying media content in each zone group. Systems and methods disclosed herein allow for easy re-access to and re-instantiation of previous configurations of one or more zone groups.

[70] Example embodiments disclosed herein enable storage of configuration data for a multiple-zone group scene, the configuration data including the configuration of the multiple zone groups in the media playback system. For example, after the command to store the configuration of the multiple zone groups as a multi-zone group scene of the media playback system, the configuration data may be stored at a controller, a zone player, and/or a networked attached storage device, etc., in the media playback system. In some examples, the controller stores the configuration data and transmits the configuration data to a zone player in the media playback system. The zone player may then transmit the configuration data to other zone players in the media playback system regardless of current zone grouping. In other examples, the controller stores the configuration data and transmits the configuration data to the zone player at the time the multi-zone group scene is requested to be instantiated. In yet other examples, the zone player may transmit the configuration data to the controller and/or other controllers associated with the media playback system. For example, the zone player may store the configuration data and transmit the configuration data to the controller to be used for selection and re-instantiation. In other examples, an external storage (e.g., a computer, network attached storage, etc.) can store the configuration data, which is then retrieved by the zone player and/or controller for use, display, selection, and so on.

[71] In some examples, a first zone group of the multiple zone groups contains more than one zone player and a second zone group of the multiple zone groups contains at least one zone player. In other examples, all zone groups in the media playback system may be grouped into a multi-zone group scene. Conversely, in yet other examples, no zone groups may be included in the multi-zone group scene. However, it will be appreciated from the disclosed embodiments that any combination of zone groups (regardless of the number of zone players associated with each group) may be selected for configuration in a multi-zone group scene.

[72] Example embodiments disclosed herein return to and/or instantiate the multi-zone group scene (e.g., in response to a user command to do so), by transmitting a command to trigger the multi-zone group scene to at least a first zone player in the media playback system. For example, when a multi-zone group scene is selected to be instantiated (e.g., via a user interface of a controller) the controller transmits the command to a zone player in the media playback system. When the zone player receives the command, the zone player may relay the
command to at least one other zone player in the media playback system. In some examples, the command to instantiate the multi-zone group scene (e.g., transmitted from the controller to the first zone player) includes the configuration data for the multi-zone group scene. In other examples, the command to instantiate the multi-zone group scene causes at least one zone player to instantiate the multi-group scene according to configuration data previously stored by the at least one zone player. In other examples, the controller transmits the command to instantiate to more than one zone player in the media playback system.

In some examples, the controller interface may be used to create a "snapshot" of the current state of the media playback system and store the snapshot as a multi-zone group scene. For example, a selection to snapshot the media playback system can trigger the storing of the configuration of each zone group in the media playback system. The example snapshot may be associated with an identification (e.g., a name provided via the controller for the multi-zone group scene) and stored locally at the controller and/or a zone player of the media playback system. The identification may be later used to re-instantiate the snapshot of the media playback system at a later time.

In an illustrative example, a controller in a media playback system is used create a multi-zone group scene for a game day experience in a household. On or before the first game day for a particular sports team, the controller is used to configure different zone groups to provide unique content associated with the game providing a uniquely tailored auditory game day experience. For example, a kitchen zone group (e.g., the kitchen zone group comprising at least one zone player) is configured to present audio associated with a radio broadcast (e.g., the home radio play-by-play) and a living room zone group and a patio zone group (e.g., the living room and patio zone groups each including multiple zone players) are configured to present audio from a television broadcast of the game. Additionally, one or more other zone(s) (e.g., a bathroom zone, foyer zone, etc.) may also be configured to play music (e.g., streaming audio) while the kitchen, living room, and patio zone groups are playing game-related content. Further options may also be configured in conjunction with the multi-zone group scene such as, for example, a) a volume level for audio playback for each zone in the zone group, b) a mute or unmute setting for audio playback, c) media content for playback, d) a play mode setting, e) an equalization setting for audio playback, and f) an audio alarm (e.g., these options are not considered to be exhaustive, in fact, many other options may be saved in conjunction with audio and/or equalization settings with regard to the multi-zone group scene).

When the media playback system is configured for the game day multi-zone group scene, the controller detects a selection to create a multi-zone group scene and stores the
current multi-zone groupings and each zone group's configuration as a "Gameday" multi-zone group scene. Configuration data for the multi-zone group scene for the game day experience is saved so that the "Gameday" scene may be instantiated again with the selection of the "Gameday" multi-zone group scene. For example, the configuration data may be stored on the controller and/or a zone player in the media playback system. That is, on future game days, the "Gameday" multi-zone group scene may be re-instantiated without having to reconfigure each zone group in the media playback system.

[76] In some examples, a stored multi-zone group scene is invoked in response to an alarm configured via the controller and/or other interface. For example, a certain multi-zone group scene may be instantiated in response to a zone player detecting the controller is in proximity to the zone player. As another example, the media playback system may be in communication with other devices in the homes (e.g., via Internet of Things (IoT), Bluetooth™, Wi-Fi, and/or other communication protocol) such that a multi-zone group scene may be instantiated when certain actions in the home are detected. Such actions include unlocking and/or opening of doors, turning on lights, motion detection, etc.

[77] Figure 5A shows an example user interface 500 that may be displayed on a computing device and/or controller to create and store a multi-zone group scene. The interface 500 includes a zone groups menu option 502 and a graphical indicator 505 for a command to "Use Scenes." The "Use Scene" command is an example command to store a configuration of multiple zone groups as a multi-zone group scene.

[78] For example, when the graphical indicator 505 is selected, further options including the current zone groups appear in the interface 500 (e.g., a list and/or a representation of current zone groups). In the illustrated example, the selection of graphical indicator 505 reveals (1) zone groups in the media playback system (living room 510 and patio 515), (2) grouping options for each of the particular zone groups (e.g., living room grouping option 510G and patio grouping option 515G), and (3) a second graphical indicator 520 to store and/or save the multi-zone group scene (e.g., "Save Scene"). Selection of the second graphical indicator 520 stores configuration data regarding current groupings of the zone groups in the media playback system as a multi-zone group scene. In some examples, zone groups may be selectively included in the multi-zone group scene using "group" indicators depicted in the interface 500. In yet other examples, check marks, radio buttons, and/or other icons may be used in place of "group indicators."

[79] In the illustrated example, the living room zone group contains at least two zone players and the patio zone group contains at least one zone player. However, in other examples, the patio zone group may include more than one zone player.
Alternatively, an additional icon may be shown in the interface 500 that, when selected, captures a snapshot of the media playback system. For example, when the media playback system is configured to a user’s preference, depressing and/or selecting the additional icon captures and stores a configuration of multiple zone groups as a multi-zone scene. That is, the current state of the media playback system (e.g., including current groupings, media playback, volume and/or equalization setting, network connections, system state variable(s), routing table, playlist, queues, etc.) is saved as a multi-zone group scene. Essentially, this option creates a snapshot of the current state of the media playback system. This snapshot option serves as another option to generate a multi-zone group scene for the media playback system. For example, in the above Gameday scenario, the snapshot option may be selected after configuring the media playback system to the desired operation offering an expedited option for multi-zone group scene generation. These snapshot multi-zone group scenes may be stored and recalled (e.g., re-instantiated) in the same way as non-snapshot multi-zone group scenes. That is, the snapshot multi-zone group scenes may be stored on local storage of zone players, stored on the controller, and/or stored in a remote server that may be referenced and/or obtained by a zone player and/or controller.

In some examples, an option to cancel the storage of the multi-zone group scene may be provided in the example interface 500.

Figure 5B shows an embodiment of the user interface 500 of Figure 5A after the command to save the multi-zone group scene has been detected. In the illustrated example, a prompt 530 is presented to the user to name the stored multi-zone group scene. The example multi-zone group scene of Figure 5B is named "Party" in the prompt 530. When the name of the multi-zone group scene is provided in the prompt 530, selecting the graphical "Save" indicator 540 stores the multi-zone group scene. In some examples, where a name is not provided in the prompt, a default name may be assigned to the multi-zone group scene. In other examples, an option is provided in the interface 500 to delete previously stored multi-zone group scenes.

Figure 6 depicts an example data structure 600 containing configuration data for different multi-zone group scenes. While the data structure can be implemented in many other ways (e.g., a state/look up table, topology/configuration parameter, etc.), In the illustrated example, the data structure contains data for a Living Room zone group (e.g., including a plurality of zone players) and is stored on both the controller for the media playback system and a first zone player of the plurality of zone players in the example Living Room zone group. As discussed above, however, the configuration data may be stored in a variety of ways over multiple embodiments.
The example data structure contains media playback system identification data including a self-identification and an identification of other zone groups in the media playback system. The data structure further includes configuration data for a plurality of multi-zone group scenes.

For example, the BBQ multi-zone group scene configuration data includes one or more parameters specifying a volume level and an associated media source location to be presented when the BBQ multi-zone group scene is instantiated. The BBQ multi-zone group scene also includes an identification of other zone groups (e.g., one or more of which include multiple zone players, etc.) that are configured for media playback when the BBQ multi-zone group scene is instantiated. In the illustrated example of Figure 6, the BBQ multi-zone group scene further includes a parameter or other setting that identifies members of the multi-zone group scene to present the same media (e.g., the Source_ALL parameter). This parameter, as explained in further detail below, allows for a variety of media to be presented in different zone groups when the multi-zone scene is instantiated. Alternatively, in some examples, there may be an indication of no media to be presented. That is, the absence of a media source indicates no pre-configured media is to be presented when the multi-zone group scene is instantiated (or re-instantiated).

The Gameday multi-zone group scene configuration data includes an additional parameter to exclude certain zone groups from inclusion in the multi-zone group scene. In the illustrated example, the Gameday multi-zone group scene includes configuration data that excludes the "Nursery" zone group from being included in the Gameday multi-zone group scene. For example, if the nursery zone group was identified as an excluded zone, the nursery zone group would not be available to add to the Gameday multi-zone group scene until the nursery zone group was no longer identified as an excluded zone group (e.g., through removal via a user interface of a controller and/or computing device). Thus, if the Nursery were grouped with the Kitchen zone group prior to invocation of the Gameday multi-zone group scene and Kitchen was part of the scene but Nursery was not, instantiation of the scene would break the Nursery-Kitchen grouping and would not include the Nursery in the Gameday configuration.

In certain examples, however, an exclude zone group (e.g., Nursery) could be added after the scene is invoked (e.g., manually by user and/or another override setting, parameter, etc.). Thus, for example, if the Nursery was excluded in the saved Gameday multi-zone group scene configuration, the Nursery could be added after instantiation of the scene, and such addition of the Nursery zone group could be temporary and/or could be added to update a stored Gameday multi-zone group scene configuration, for example. In other examples, if
the Nursery were grouped with the Kitchen prior to instantiation of the Gameday scene, the existing grouping could result in the Nursery being automatically brought into the Gameday multi-zone group scene based on its existing grouping with the Kitchen zone group (which was already part of the stored Gameday scene configuration).

The Party multi-zone group scene configuration data 620 includes additional membership parameters identifying zone groups belonging to the multi-zone group scene via zone scene identifiers (e.g., zone group and/or multi-zone group scene names). For example, via the controller, two or more previously created multi-zone group scenes may be combined into a new group scene. In the illustrated example, the membership parameters identify the zone groups by previously created multi-zone group scenes. For example, using the user interface of the controller, the Party multi-zone group scene is created by selecting the BBQ and Gameday multi-zone group scenes to create a combined multi-zone group scene including the configuration information of both the BBQ and Gameday multi-zone group scenes. For example, the membership of the Party multi-zone group scene includes the zone groups identified in the configuration data 610, 615 of the BBQ and Gameday multi-zone group scenes.

Additionally, the Party multi-zone group scene can include a plurality of media sources for playback. The Party multi-zone group scene configuration data includes parameters identifying two sources as well as an identification of which zones are to present which media upon the instantiation of the Party multi-zone group scene. While the media sources are depicted as uniform resource locators (URLs) and uniform resource indicators (URIs), any compatible instruction and/or parameter may be included as a source to be presented via the media playback system or playback device. Some media source examples that may be referenced in this parameter include source devices, playlist identifications, media files, radio frequencies, etc.

It will be appreciated from the foregoing that the examples provided in the configuration data are not to be construed to be limiting in any way. In fact, the configuration data may be scaled to fit the desires of the creator of the multi-zone group scene and store as much or as little information as required and/or desired. These examples were provided to illustrate a simple embodiment of configuration data for multi-zone group scene creation.

Figure 7 shows an embodiment of a user interface 700 for instantiating a multi-zone group scene. In the illustrated example, the selection of "Zone Scenes" 705 reveals a menu of available multi-zone group scenes for the media playback system such as "Party" 710, "BBQ" 715, and "Gameday" 720. These multi-zone group scenes have been generated in accordance with embodiments disclosed herein. The multi-zone group scenes of the zone scene menu 705 may be stored locally on the controller and/or on a zone player in the media playback system.
and/or in a remote server accessible by a zone player and/or controller. The list of available zone scenes 705 may be refreshed by polling the zone players and/or local storage of the controller and/or remote server to determine stored multi-zone group scenes for display in the zone scene menu 705. When a name and/or other indicator (e.g., an icon) of the desired multi-zone group scene is selected via the interface 700, the controller (e.g., control device 300) obtains (or instructs the zone player to obtain) configuration data associated with the desired multi-zone group scene. The controller also transmits a command to a zone player to load, utilize, and/or operate under the configuration data associated with the desired multi-zone group scene.

Flow diagram 800 shown in Figure 8 presents an embodiment of a method that can be implemented within an operating environment involving, for example, the media playback system 100 of Figure 1, one or more of the playback device 200 of Figure 2, and one or more of the control device 300 of Figure 3. Method 800 may include one or more operations, functions, or actions as illustrated by one or more of blocks 805-840. Although the blocks are illustrated in sequential order, these blocks may also be performed in parallel, and/or in a different order than those described herein. Also, the various blocks may be combined into fewer blocks, divided into additional blocks, and/or removed based upon the desired implementation.

In addition, for the method 800 and other processes and methods disclosed herein, the flowchart shows functionality and operation of one possible implementation of present embodiments. In this regard, each block may represent a module, a segment, or a portion of program code, which includes one or more instructions executable by a processor for implementing specific logical functions or steps in the process. The program code may be stored on any type of computer readable medium, for example, such as a storage device including a disk or hard drive. The computer readable medium may include non-transitory computer readable medium, for example, such as computer-readable media that stores data for short periods of time like register memory, processor cache and Random Access Memory (RAM). The computer readable medium may also include non-transitory media, such as secondary or persistent long term storage, like read only memory (ROM), optical or magnetic disks, compact-disc read only memory (CD-ROM), for example. The computer readable media may also be any other volatile or non-volatile storage systems. The computer readable medium may be considered a computer readable storage medium, for example, or a tangible storage device. In addition, for the method 500 and other processes and methods disclosed herein, each block in Figure 5 may represent circuitry that is wired to perform the specific logical functions in the process.
Figure 8 is a flowchart of example instructions 800 for storing configuration data for a multi-zone group scene. The example instructions 800 begin when a controller is powered on. When the controller monitors for a request to store a configuration for a multi-zone group scene (block 805). For example, a request to store a "Gameday" multi-zone group scene as discussed above may be detected. In other examples, this request to store a configuration may be a snapshot multi-zone group scene command. If no request to store a multi-zone group scene is detected, the controller device continues to monitor for such a request.

If a request to store a multi-zone group scene is detected, the controller determines if zone groups are selected to be included in the multi-zone group scene (block 810). For example, the desired multi-zone group scene may only include particular ones of zone groups and/or zone players in the media playback system. In the Gameday example, the kitchen and the living room are the only zone groups included in the Gameday multi-zone group scene. If no zone groups are selected to be included in the multi-zone group scene, the controller waits until zone groups are selected. In some examples, the controller presents the user with an option to select media to be associated with the multi-zone group scene as a whole or the zone groups individually. In other examples (e.g., a snapshot multi-zone group scene), the controller includes all zone groups in the media playback system in the multi-zone scene. When the zone group selection is finalized (e.g., a selection of a save button on the interface of the controller), the controller stores the selected zone groups and associated media as parameters in the configuration data of the multi-zone group scene (block 815). For example, the living room and kitchen zone groups and associated parameters in the Gameday example (e.g., volume, media content for playback, play mode setting, equalization, alarms, system state variable(s), routing table, playlist, etc.) are stored as the Gameday multi-zone group scene.

At block 820, the controller determines if any zone groups are to be excluded from the multi-zone group scene. For example, a certain zone group may be selected for exclusion for one or more reasons (e.g., an unoccupied zone of the household, a quiet zone, a zone occupied by one not desiring to hear audio, etc.) via the interface of the controller. If there are zone groups to be excluded from the multi-zone group scene, the controller generates a parameter for the configuration data indicating the desired zone group is to be excluded from the multi-zone scene upon instantiation (block 825) and proceeds to block 830. For example, in continuing the Gameday example, an area of the house for household members not desiring to experience the game may be excluded (e.g., a bedroom, office, etc.). If no zone groups are selected for exclusion from the multi-zone group scene, control proceeds to block 830.

The controller then determines if any additional configuration parameters are to be
included in the configuration data for the multi-zone group scene (block 830). Additional configuration parameter examples include (1) a name of the multi-zone group scene and/or (2) zone group and/or multi-zone scene global parameters such as volume, equalizations, playlists, queues, communication protocols, player orientation, system state variable(s), routing table, playlist, etc. For example, the Gameday multi-zone group scene may be named, configured, and/or fine tuned. That is, if, for example, the living room zone group of the Gameday multi-zone group scene is currently configured to a music focused equalization setting, block 830 provides the ability to alter the equalization settings to a vocal broadcast and/or sports focused equalization (e.g., for a zone group in the multi-zone group scene, or globally for the multi-zone group scene). If additional configuration parameters are detected, the controller incorporates them into the configuration data for the multi-zone group scene (block 835). If no additional configuration parameters are detected, control proceeds to block 837.

[98] In the illustrated example, the controller stores the configuration data for the multi-zone group scene on the controller (block 837). For example, the configuration data for the Gameday multi-zone group scene is stored at the controller. At the same time or shortly thereafter, the controller transmits the configuration data for the multi-zone scene to at least one zone player in at least one zone group (block 840). For example, the configuration data for the Gameday multi-zone group scene is transmitted to a first zone player in the media playback system. Alternatively, the configuration data for the multi-zone group scene is not stored at the controller. For example, the configuration data for the Gameday multi-zone group scene may be stored at the zone player that received the transmission containing the configuration data for the Gameday multi-zone group scene (e.g., the first zone player). In other examples, the configuration data for the multi-zone group scene may be transmitted to and/or stored at a remote server and/or other network-attached storage.

[99] In some examples, the configuration data for the multi-zone group scene is transmitted to a random zone player. In other examples, the configuration data for the multi-zone group scene is transmitted to a designated "head" zone player. For example, the "head" zone player may be determined using a round-robin algorithm. In other example, the configuration data for the multi-zone group scene is not transmitted to a zone player until such time that the multi-zone group scene is to be instantiated.

[100] In the illustrated example, when the configuration data for the multi-zone group scene is transmitted, the example instructions terminate. In some examples, however, control may return to block 805 and continue to monitor for another request to save a multi-zone group scene. For example, the controller may await further instructions after the Gameday multi-zone group
scene configuration data is transmitted to the first zone player. When the multi-zone group scene configuration data is transmitted to a zone player, the multi-zone group scene configuration data is stored at the zone player and relayed to other zone players in the media playback system. Figure 9 provides an example flowchart for example instructions that may be used in an example embodiment to achieve such storing at a zone player.

[101] Figure 9 is a flowchart of example instructions 900 for storing configuration data for a multi-zone group scene at a playback device. The example instructions 900 begin when a zone player is powered on. The zone player monitors for a multi-zone group scene configuration data transmission from a controller (block 905). When the configuration data is received by the playback device, the playback device stores the configuration data on a local non-transitory memory (block 910). The playback device then determines if there are the other zone groups in the multi-zone group scene from the configuration data (block 915). If other zone groups are included in the multi-zone group scene, the playback device acts as a relay and transmits the configuration data to the other zone groups (block 920). If no other zone groups are included in the multi-zone group scene the instructions end. Likewise, once the configuration data has been transmitted to the other zone groups the instructions end. In some examples, however, control may return to block 905 and continue to monitor for another multi-zone group scene configuration data transmission from the controller.

[102] Figure 10 is an example flowchart of example instructions 1000 for instantiating a multi-zone group scene at a controller. The example instructions 1000 begin when the controller is powered on. The controller monitors for a request to instantiate a stored multi-zone group scene (block 1005). When the request is detected, the controller determines if the multi-zone group scene configuration data is stored locally (e.g., on the controller) (block 1010). If the multi-zone group scene configuration data is stored locally, the controller generates a command to trigger the multi-zone group scene at a zone player that includes the multi-zone group scene configuration data (block 1015). For example, the generated command to trigger may further include data for parameters such as volume, media content, play mode setting, equalization, alarms, network configurations and/or topology, system state variable(s), routing table, playlist, etc. The generated command including the multi-zone group scene configuration data is transmitted by the controller to a first playback device (block 1020).

[103] If the multi-zone group scene configuration data is not stored locally on the controller, the controller assumes that the multi-zone group scene configuration data is stored at a playback device and/or remote server. To that end, the controller transmits a command to instantiate the multi-zone group scene to a first zone player without multi-zone group scene configuration
data (block 1025). When the command to instantiate is transmitted, a zone player must analyze the command and, in some examples, the included multi-zone group scene configuration data. Figure 11 provides an example embodiment of such command analysis at a zone player.

[104] Figure 11 is an example flowchart of example instructions 1100 for instantiating a multi-zone group scene at a playback device. The example instructions 1100 begin when the playback device is powered on. The playback device monitors for a command to instantiate a stored multi-zone group scene (block 1105). When the command is received, the playback device determines if the multi-zone group scene configuration data was transmitted with the command (block 1107). If the multi-zone group scene configuration data was not stored in the command, the playback device determines if the multi-zone group scene configuration data is stored locally (block 1108). If the multi-zone group scene configuration data is not stored locally, the playback device transmits an error message (block 1109) indicating the multi-zone group scene cannot be instantiated with this playback device. Control terminates after the transmission of the error message.

[105] Returning to blocks 1107 and 1108, if the multi-zone group scene configuration data is stored locally or transmitted with the instantiation command, the playback device relays the command to instantiate the multi-zone group scene to the other zone groups in the multi-zone group scene (block 1110). The playback device then begins operation using the configuration data for the multi-zone group scene (block 1115). The playback device continues to operate under the configuration data for the multi-zone group scene until instructed otherwise and/or powered down.

[106] Figure 12 is a flowchart of example instructions 1200 for storing configuration data for a multi-zone group scene. The example instructions 1200 begin when a controller is powered on. The example controller facilitates, via a user interface of a controller, storage of a configuration of multiple zone groups as a multi-zone scene of a media playback system (block 1205). For example, the media playback system includes at least a first zone group including at least two zone players and a second zone group. The user interface of the controller facilitates the storage of the configuration of multiple zone groups as a multi-zone group scene by, for example, presenting at least an indication of (1) the first zone group, (2) the second zone group, and (3) a multi-zone group scene creation command.

[107] The example controller generates, for example, based on a detected triggering of the multi-zone group scene creation command, a multi-zone scene configuration including stored configuration data for the first zone group and the second zone group to instantiate the multi-zone scene (block 1210). For example, the configuration data is based on identified
parameters associated with the captured configuration of the multiple zone groups of the media playback system. Such identified parameters may be identified and/or their selection facilitated via the controller. For example, the parameters may include zone players currently associated with the first zone group and the second zone group, an indication that the first zone group and the second zone group belong to the multi-zone group scene, media to be presented via the multi-zone group scene, network configuration, etc.

The controller transmits the configuration data to at least the first zone player in the first zone group for subsequent instantiation of the multi-zone group scene. For example, the controller may store the configuration data first and then transmit the configuration data to a zone player. In other examples, the controller transmits the configuration data to a remote server storing multi-zone group scene configuration data. Additionally, the zone player may then transmit the configuration data to other zone players in the media playback system regardless of current zone grouping. In other examples, the controller stores the configuration data and transmits the configuration data to the zone player at the time the multi-zone group scene is requested to be instantiated. In yet other examples, the zone player may transmit the configuration data to the controller and/or other controllers associated with the media playback system. The example instructions 1200 end when the configuration data has been transmitted to from the controller.

Figure 13 is an example data flow diagram in the media playback system with respect to a snapshot multi-zone group scene generation command and a later instantiation of the snapshot multi-zone group scene.

In normal operation, the controller 1305 sends commands to a first playback device 1310 (1320). In some examples, the controller 1305 sends a command to the first playback device to dictate or direct the first playback device 1310 with respect to media to be presented on the first playback device 1310. For example, the controller 1305 may send a command to trigger the first playback device to play a Thelonious Monk playlist.

The example first playback device 1310 responds to the command of the controller 1305 with an acknowledgement of the command (1325). In some examples, the first playback device 1310 may include in the acknowledgement message 1325 parameters indicative of the current status of the first playback device such as, for example, network status, current media playback status, details and/or metadata descriptive of files stored locally at the first playback device 1310, etc.

At some time later, a snapshot command to create a multi-zone group scene is generated at the controller 1305. The snapshot multi-zone group scene generation
command is communicated to the first playback device 1310 (1330). The command for the snapshot multi-zone group scene triggers the receiving playback device to transmit the current configuration data that the playback device is operating subject to. For example, such information may include current zone grouping, media playback, audio and/or equalization settings, network configuration etc. The first playback device 1310 routes the snapshot multi-zone group scene generation command to at least a second playback device 1315 in the media playback system (1333).

[113] In some examples, the first playback device 1310 broadcasts the snapshot multi-zone group scene generation command to all devices in the media playback system. In yet other examples, the second playback device 1315 broadcasts the snapshot multi-zone group scene generation command to a third playback device which, in turn, transmits the snapshot multi-zone group scene generation command to a fourth playback device. This example process may repeat until such a time all playback devices in the media playback system have received the snapshot multi-zone group scene generation command.

[114] The first playback device 1310 transmits current configuration data associated with the first playback device 1310 back to the controller 1305 in response to receiving the snapshot multi-zone group scene command (1335). For example, current configuration data may include network status, current media playback status, details and/or metadata descriptive of files stored locally at the playback device, current volume, current media content and/or source being presented at the first playback device, current playback queue, current play mode setting, current equalization, active and/or inactive alarms, system state variable(s), routing table, playlist, etc. Similarly, the second playback device 1315 transmits current configuration data associated with the second playback device 1315 back to the controller 1305 in response to the snapshot multi-zone group scene command (1340). Again, such information may include, for example, current zone grouping, media playback, audio and/or equalization settings, network configuration, etc. associated with the corresponding playback device.

[115] The current configuration data associated with the first playback device 1310 and the second playback device 1315 are transmitted back to the controller 1305 so that the controller 1305 may generate configuration data for the snapshot multi-zone group scene in accordance with methods disclosed herein. For example, the current configuration data associated with the first playback device 1310 and the second playback device 1315 are stored in a file and/or data structure and associated with an indicator or name such that the snapshot multi-zone group scene may be later instantiated. That is, the state of the media playback system at the time of the snapshot (e.g., a snapshot multi-zone group scene) may be returned to at a later time. The
generated configuration data file and/or data structure contains multi-zone group scene configuration data for the snapshot of the media playback system. In sum, the controller 1305 gathers the configuration data for the playback devices in the media playback system and forms the gathered configuration data into multi-zone group scene configuration data.

[116] When the controller 1305 has generated the multi-zone group scene configuration data for the snapshot, the controller 1305 transmits the generated multi-zone group scene configuration data for the snapshot multi-zone group scene to the first playback device 1310 (1345). The first playback device 1310 stores the multi-zone group scene configuration data for the snapshot multi-zone group scene. In the example Figure 13, the controller 1305 does not store the multi-zone group scene configuration data, rather the controller 1305 only stores an indication that a snapshot multi-zone group scene exists and not the actual configuration data for the snapshot multi-zone group scene itself. The storage of the multi-zone group scene configuration data in the illustrated example is located at the first playback device 1310. However, it will be appreciated that, in some examples, the controller 1305 and/or a remote server may be configured to store the multi-zone group scene configuration data for the snapshot multi-zone group scene.

[117] Returning to the example Figure 13, at a later time, the controller 1305 generates a command to instantiate the snapshot multi-zone group scene and transmits the command to instantiate to a first playback device 1310 (1350). This command to instantiate the snapshot multi-zone group scene is acknowledged by the first playback device 1310 (1355). Accordingly, the first playback device 1310 begins operating subject to the multi-zone group scene configuration data for the respective snapshot multi-zone group scene. The first playback device 1310 transmits the multi-zone group scene configuration data and a command to instantiate the snapshot multi-zone group scene to the second playback device 1315 (1360). The second playback device 1315 begins operating subject to the multi-zone group scene configuration data for the snapshot multi-zone group scene.

[118] In some examples, the first playback device 1315 broadcasts the snapshot multi-zone group scene configuration data and command to instantiate to all devices in the media playback system. In yet other examples, the second playback device 1315 broadcasts the snapshot multi-zone group scene configuration data and command to instantiate to a third playback device which, in turn, transmits the snapshot multi-zone group scene configuration data and command to instantiate to a fourth playback device. This example process may repeat until such a time all playback devices in the media playback system have received the snapshot multi-zone group scene configuration data and command to instantiate.
IV. Conclusion

[119] The description above discloses, among other things, various example systems, methods, apparatus, and articles of manufacture including, among other components, firmware and/or software executed on hardware. It is understood that such examples are merely illustrative and should not be considered as limiting. For example, it is contemplated that any or all of the firmware, hardware, and/or software aspects or components can be embodied exclusively in hardware, exclusively in software, exclusively in firmware, or in any combination of hardware, software, and/or firmware. Accordingly, the examples provided are not the only way(s) to implement such systems, methods, apparatus, and/or articles of manufacture.

[120] Additionally, references herein to "embodiment" means that a particular feature, structure, or characteristic described in connection with the embodiment can be included in at least one example embodiment of an invention. The appearances of this phrase in various places in the specification are not necessarily all referring to the same embodiment, nor are separate or alternative embodiments mutually exclusive of other embodiments. As such, the embodiments described herein, explicitly and implicitly understood by one skilled in the art, can be combined with other embodiments.

[121] The specification is presented largely in terms of illustrative environments, systems, procedures, steps, logic blocks, processing, and other symbolic representations that directly or indirectly resemble the operations of data processing devices coupled to networks. These process descriptions and representations are typically used by those skilled in the art to most effectively convey the substance of their work to others skilled in the art. Numerous specific details are set forth to provide a thorough understanding of the present disclosure. However, it is understood to those skilled in the art that certain embodiments of the present disclosure can be practiced without certain, specific details. In other instances, well known methods, procedures, components, and circuitry have not been described in detail to avoid unnecessarily obscuring aspects of the embodiments. Accordingly, the scope of the present disclosure is defined by the appended claims rather than the forgoing description of embodiments.

[122] When any of the appended claims are read to cover a purely software and/or firmware implementation, at least one of the elements in at least one example is hereby expressly defined to include a tangible, non-transitory medium such as a memory, DVD, CD, Blu-ray, and so on, storing the software and/or firmware.
We Claim:

1. A method for configuring, via a user interface (500) of a controller, a multi-zone scene of a media playback system comprising at least first and second zones (510, 515), the first zone (510) comprising at least two zone players, the method comprising:
   - detecting a user input for generating a multi-zone scene;
   - in response to detecting the trigger, storing a multi-zone scene configuration of a plurality of zone groups including:
     - an indication of the plurality of zone groups that belong to the multi-zone group scene;
     - stored configuration data for the plurality of zone groups including the zone players currently associated with the plurality of zone groups; and
   - transmitting the configuration data to at least a first zone player in the first zone group for subsequent instantiation of the multi-zone group scene.

2. The method of any preceding claim, wherein the user input for generating a multi-zone scene is a user input for generating a multi-zone scene of a current configuration of each zone group of the media playback system, and the stored multi-zone scene configuration includes configuration information for each zone group of the media playback system according to the current configuration of each zone group.

3. The method of claim 1, further comprising allowing a user to include one or more zone groups to the multi-zone scene by selecting a corresponding one or more graphical indications of the one or more zone groups.

4. The method of any preceding claim, further comprising, in response to detecting a selection of the stored multi-zone scene, instantiated the multi-zone scene.

5. The method of any of claims 1 to 3, further comprising, in response to an alarm configured via the controller, instantiating the multi-zone scene.

6. The method of claim 4, wherein the alarm corresponds to at least one of:
   - a particular zone player detecting that the controller is within a predetermined proximity
to the zone player;
  unlocking of a door;
  opening of a door;
  turning on lights; and
  motion detection.

7. The method of any preceding claim, further comprising allowing a user to add or remove a zone group from the saved multi-zone scene configuration.

8. The method of any preceding claim, wherein the configuration data further comprises:
   first media to be played back by the first zone group; and
   second media to be played back by the second zone group.

9. The method of any preceding claim, further comprising, in response to a corresponding user input, combining two saved multi-zone scenes into a new multi-zone scene.

10. The method of any preceding claim, wherein the stored configuration data further comprises configuration data to cause the first zone player in the first zone group to transmit the configuration data to other zone players in the media playback system.

11. The method of any preceding claim, further comprising:
    in response to detecting a selection of the stored multi-zone group scene, instantiating the multi-zone group scene by transmitting, to at least the first zone player in the first zone group, a command to trigger the multi-zone group scene and to trigger the first zone player to transmit the command to at least the second zone player in the second zone group.

12. The method of any preceding claim, wherein the stored configuration data further comprises one or more of:
    a volume level for audio playback for each zone in the zone group;
    a mute or unmute setting for audio playback;
    media content for playback;
    a play mode setting;
an equalization setting for audio playback;
an audio alarm; and
media content currently associated with the first zone group and the second zone group.

13. The method of any preceding claim, further comprising,
in response to detecting the user input for generating the multi-zone scene, allowing the user to provide a name for the multi-zone group scene; and
associating the generated configuration data to the name.

14. An apparatus comprising:
a memory; and
a processor configured to perform the method of any preceding claim.

15. A non-transitory computer readable storage medium comprising instructions that when executed cause a processor to perform the method of any preceding claim.

## INTERNATIONAL SEARCH REPORT

### A. CLASSIFICATION OF SUBJECT MATTER

INV. H94R27/00 H04R29/00
ADD.

According to International Patent Classification (IPC) or to both national classification and IPC

### B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

H04R

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

### C. DOCUMENTS CONSIDERED TO BE RELEVANT

<table>
<thead>
<tr>
<th>Category</th>
<th>Citation of document, with indication, where appropriate, of the relevant passages</th>
<th>Relevant to claim No.</th>
</tr>
</thead>
</table>

Further documents are listed in the continuation of Box C.

See patent family annex.

**A** document defining the general state of the art which is not considered to be of particular relevance

**E** earlier application or patent but published on or after the international filing date

**L** document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

**O** document referring to an oral disclosure, use, exhibition or other means

**P** document published prior to the international filing date but later than the priority date claimed

**T** later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

**X** document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

**Y** document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

**F** document member of the same patent family

**D** document of further interest but not relevant to patentability

Date of the actual completion of the international search
