(57) Abrégé/Abstract:
Provided is a means that can prevent the initial excessive release of an active ingredient and sustainedly release said active ingredient in a therapeutically effective amount over a long period of time.

ABSTRACT

Provided is a means that is capable of preventing initial excessive release of an active ingredient, and that allows for sustained release of a pharmaceutically active amount of the active ingredient over a long period of time.

Date Reçue/Date Received 2022-02-11

DESCRIPTION

Title of Invention: ORAL PHARMACEUTICAL COMPOSITION

Technical Field

[0001]

The present disclosure relates to an oral pharmaceutical composition containing a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one (more preferably a controlled release oral pharmaceutical composition), and the like. The contents of all of the documents mentioned in the present specification are incorporated herein by reference.

Background Art

[0002]

7-[4-(4-Benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one (hereinafter also referred to as compound (I) or brexpiprazole), or a salt thereof, has a dopamine D_2 receptor partial agonistic action, a serotonin 5-HT_{2A} receptor antagonistic action, and an adrenergic α_1 receptor antagonistic action. In addition to those actions, compound (I) or a salt thereof has a serotonin uptake inhibitory action (or a serotonin reuptake inhibitory action), and is known to have a broad therapeutic spectrum for central nervous system (CNS) diseases (particularly schizophrenia) (Patent Literature (PTL) 1).

Summary of Invention

Technical Problem

[0004]

In the treatment of CNS diseases, such as schizophrenia, it is generally important for the drug to be present in plasma at a

therapeutically effective concentration over a long period of time. Therefore, a pharmaceutical composition for oral administration that can be administered at low frequency is useful in that it increases patient compliance, and reduces the recurrence rate during treatment. To obtain a pharmaceutical composition for oral administration that can be administered at low frequency, producing a composition containing a high dose of an active ingredient can be considered. However, in order to maintain a blood concentration effective for treatment, the active ingredient is required to be continuously released from the composition at an appropriate rate while preventing excessive release after administration due to factors concerning the living body.

[0005]

In the treatment of schizophrenia using compound (I) or a salt thereof, once-daily oral administration is recommended at present. However, once-daily oral administration places an undue burden on many patients who require long-term administration. Therefore, there has been a demand for an orally administrable pharmaceutical composition that is suitable for less frequent administration than once-daily administration.

Solution to Problem

[0006]

The present inventors conducted extensive research, and found, for the first time, a composition containing a salt of compound (I) as an orally administrable pharmaceutical composition suitable for less frequent administration than once-daily administration.

[0007]

The present disclosure includes, for example, the subjects described in the following Items.

Item 1.

A controlled release oral solid pharmaceutical composition comprising a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one as an active ingredient, and further

comprising an additive containing an ion in common with the salt.

Item 2.

The composition according to Item 1, wherein the active ingredient is a fumaric acid salt, a phosphoric acid salt, a hydrochloric acid salt, a sulfuric acid salt, a citric acid salt, or a tartaric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

Item 3.

The composition according to Item 1, wherein the active ingredient is a fumaric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one, and the additive containing an ion in common with the salt is at least one member selected from the group consisting of fumaric acid, monosodium fumarate, and disodium fumarate.

Item 4.

The composition according to any one of Items 1 to 3, further comprising a cellulose-based water-soluble polymer.

Item 5.

The composition according to Item 4, wherein the cellulose-based water-soluble polymer is at least one member selected from the group consisting of hydroxypropyl methylcellulose, hydroxypropyl cellulose, and methyl cellulose.

Item 6.

The composition according to any one of Items 1 to 5, which is an osmotic pump composition.

Item 7.

The composition according to Item 6, wherein the osmotic pump composition comprises a drug layer comprising a cellulose-based water-soluble polymer.

Item 8.

The composition according to Item 7, wherein the cellulose-based water-soluble polymer is hydroxypropyl methyl cellulose.

Item 9.

The composition according to any one of Items 1 to 5, which is a hydrogel sustained release composition.

Item 10.

The composition according to Item 9 comprising an enteric coating.

Item 11.

The composition according to any one of Items 1 to 10, which contains 5 mg to 70 mg of the active ingredient in terms of the weight of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

Item 12.

The composition according to any one of Items 1 to 11, wherein the blood concentration of 7-[4-(4-benzo[b]thiophen-4-ylpiperazin-1-yl)butoxy]-1H-quinolin-2-one in a steady state when orally administered to a human is maintained in the range of 15 ng/mL to 400 ng/mL for 1 week.

Item 13.

The composition according to any of Items 1 to 12, which is for use in administering a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one once a week at a dose of 5 mg to 60 mg in terms of the weight of the free base.

Item 14.

The composition according to any one of Items 1 to 13, which is for use in preventing or treating a central nervous system (CNS) disease.

Item 15.

The composition according to Item 14, wherein the composition is for preventing or treating a CNS disease selected from the group consisting of schizophrenia; treatment-resistant, refractory, or chronic schizophrenia; emotional disturbance; psychotic disorder, mood disorder; bipolar disorder; depression; endogenous depression; major depression; melancholic and treatment-resistant depression; dysthymic disorder; cyclothymic disorder; anxiety disorder; somatoform disorder; factitious disorder; dissociative disorder; sexual disorder; eating disorder; sleep disorder; adjustment disorder; substance-related disorder; anhedonia; delirium; cognitive impairment; cognitive impairment associated with neurodegenerative disease; cognitive impairment caused by neurodegenerative disease;

cognitive impairment of schizophrenia; cognitive impairment caused by treatment-resistant, refractory, or chronic schizophrenia; vomiting; motion sickness; obesity, migraine; pain; mental retardation; autism disorder; Tourette's disorder; tic disorder; attention deficit hyperactivity disorder; conduct disorder; Down syndrome; impulsive symptoms associated with dementia; and borderline personality disorder.

[0008]

Item A-1.

A pharmaceutical formulation, which is an oral solid formulation of an osmotic pump controlled release system having a structure such that a core formulation comprising a laminate of a drug layer and a push layer is coated with a semipermeable membrane,
the drug layer comprising a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

Item A-2.

The pharmaceutical formulation according to Item A-1, wherein the salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one is a fumaric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

Item A-3.

The pharmaceutical formulation according to Item A-1 or A-2, wherein the drug layer comprises an additive containing an ion in common with the salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one. (For example, in the case of Item A-2 wherein the salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one is a fumaric acid salt, examples of additives containing an ion in common with the salt include fumaric acid, monosodium fumarate, disodium fumarate, and the like. In this case, the ion in common with the salt is fumarate ion.)

Item B-1.

The composition according to any one of Items 1 to 15, wherein the composition comprises a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one as an active ingredient, and releases the active ingredient in a sustained manner over a

period of 5 to 30 hours.

Item B-2.

The composition according to any one of Items 6 to 8, wherein the osmotic pump composition comprises a push layer containing at least one osmagent that is an inorganic salt, or a saccharide and/or a sugar alcohol.

Item B-3.

The composition according to Item B-2, wherein the osmagent is sodium hydrogen carbonate.

Item B-4.

The composition according to any one of Items 6 to 8 and Items B-2 to B-3, wherein the osmotic pump composition comprises a drug layer comprising light anhydrous silicic acid.

Item B-5.

The composition according to Item 1 or 3, which is an osmotic pump composition comprising a drug layer and a push layer, wherein the drug layer comprises a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one, an additive containing an ion in common with the salt, and a cellulose-based water-soluble polymer, and

the push layer comprises at least one osmagent that is an inorganic salt, or a saccharide and/or a sugar alcohol.

Item B-6.

The composition according to any one of Items 6 to 8 and Items B-2 to B-4, which comprises a core formulation comprising a drug layer and a push layer, wherein

the drug layer comprises

5 to 200 mg of a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one in terms of the weight of the free base,

1 to 50 mass% of an additive containing an ion in common with the salt, based on the weight of the drug layer,

5 to 94 mass% of a hydrophilic polymer, based on the weight of the drug layer,

0.1 to 5 mass% of a lubricant, based on the weight of the drug

layer, and

0.1 to 5 mass% of a fluidizer, based on the weight of the drug layer,

the push layer comprises

50 to 90 mass% of a highly swellable polymer, based on the weight of the push layer,

5 to 50 mass% of an osmagent, based on the weight of the push layer,

0.1 to 5 mass% of a lubricant, based on the weight of the push layer, and

0.1 to 2% by weight of a pigment, based on the weight of the push layer,

the core formulation comprises 5 to 25 parts by mass of a semipermeable membrane and 1 to 15 parts by mass of a water-soluble polymer membrane, based on 100 parts by mass of the core formulation,

the semi-permeable membrane comprises 70 to 100 mass% of a cellulose-based polymer and 0.01 to 30 mass% of a water-soluble flux-regulating agent, based on the weight of the semipermeable membrane, and

the composition optionally comprises a color coating layer.

Item B-7.

The composition according to Item 9 or 10, which is a composition comprising a core tablet, wherein

the composition comprises

5 to 200 mg of a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one in terms of the weight of the free base,

1 to 50 mass% of an additive containing an ion in common with the salt, based on the weight of the core tablet,

30 to 90 mass% of a sustained release base material, based on the weight of the core tablet, and

0.1 to 5 mass% of a lubricant, based on the weight of the core tablet, and

further comprises 1 to 40 parts by mass of an enteric coating per 100 parts by mass of the core tablet.

Item B-8.

A controlled release oral solid pharmaceutical composition comprising a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one as an active ingredient, and maintaining a steady-state blood concentration of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one in the range of 15 ng/mL to 400 ng/mL for 1 week, when orally administered to a human.

Item B-9.

A controlled release oral solid pharmaceutical composition comprising a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one as an active ingredient, the active ingredient being administered at a dose of 5 to 60 mg once a week in terms of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

Advantageous Effects of Invention

[0009]

According to the present disclosure, there can be provided a means that prevents initial excessive release of an active ingredient (i.e., a salt of compound (I)) from a pharmaceutical composition, even when the composition is administered in a high dose; and that allows for sustained release of a therapeutically effective amount of the active ingredient over a long period of time. This can maintain a therapeutically effective blood concentration of the active ingredient for a long period of time (about two weeks at most). Thus, according to the present disclosure, a disease (e.g., schizophrenia) responsive to a salt of compound (I) can be treated by less frequent administration than conventional methods, and the present disclosure is thus effective in improving medication compliance in patients.

[0010]

Examples of the disease responsive to compound (I) or a salt thereof include various CNS diseases such as schizophrenia; treatment-resistant, refractory, or chronic schizophrenia;,

emotional disturbance; psychotic disorder; mood disorder; bipolar disorder (e.g., bipolar I disorder and bipolar II disorder); depression; endogenous depression; major depression; melancholic and treatment-resistant depression; dysthymic disorder; cyclothymic disorder; anxiety disorder (e.g., panic attack, panic disorder, agoraphobia, social phobia, obsessive-compulsive disorder, post-traumatic stress disorder, generalized anxiety disorder, and acute stress disorder); somatoform disorder (e.g., hysteria, somatization disorder, conversion disorder, pain disorder, and hypochondria); factitious disorder; dissociative disorder; sexual disorder (e.g., sexual dysfunction, libido disorder, sexual arousal disorder, and erectile dysfunction); eating disorder (e.g., anorexia nervosa and bulimia nervosa); sleep disorder; adjustment disorder; substance-related disorder (e.g., alcohol abuse, alcohol intoxication and drug addiction, amphetamine addiction, and narcotism); anhedonia (e.g., loss of pleasure, anhedonia, iatrogenic anhedonia, anhedonia of a psychic or mental cause, anhedonia associated with depression, anhedonia associated with schizophrenia); delirium; cognitive impairment; cognitive impairment associated with Alzheimer's disease, Parkinson's disease, and other neurodegenerative diseases; cognitive impairment caused by Alzheimer's disease, Parkinson's disease, and other neurodegenerative diseases; cognitive impairment of schizophrenia; cognitive impairment caused by treatment-resistant, refractory, or chronic schizophrenia; vomiting; motion sickness; obesity; migraine; pain; mental retardation; autistic disorder (autism); Tourette's syndrome; tic disorder; attention deficit hyperactivity disorder; conduct disorder; Down syndrome; impulsive symptoms associated with dementia (e.g., agitation associated with Alzheimer's disease); and borderline personality disorder.

Description of Embodiments

[0012]

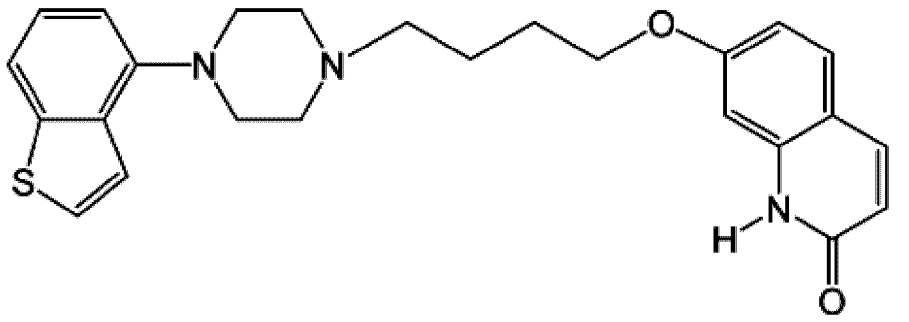
The present disclosure preferably includes an oral pharmaceutical composition, a method for producing the oral pharmaceutical composition, and the like. However, the disclosure is not limited thereto, and includes everything that is disclosed in the present invention and that can be recognized by one skilled in the art.

[0013]

The oral pharmaceutical composition according to the present disclosure includes a salt of compound (I). This oral pharmaceutical composition may be referred to as the “oral pharmaceutical composition according to the present disclosure.”

Compound (I) refers to a compound represented by the following formula (I). Compound (I) or a salt thereof can be produced by the method disclosed in JP2006-316052A (the entirety of which is incorporated herein by reference), or a method similar thereto.

[0014]



(I)

[0015]

The salt of compound (I) is not particularly limited, insofar as it is a pharmaceutically acceptable salt. Examples include various metal salts, inorganic base salts, organic base salts, inorganic acid salts, organic acid salts, and the like. Examples of metal salts include alkali metal salts (e.g., sodium salts and potassium salts), alkaline earth metal salts (e.g., calcium salts and magnesium salts), and the like. Examples of inorganic base salts include ammonium salts and salts of alkali metal carbonates (e.g., lithium carbonate, potassium carbonate, sodium carbonate, and cesium carbonate), alkali metal hydrogen carbonates (e.g., lithium hydrogen carbonate, sodium hydrogen carbonate, and potassium hydrogen carbonate), alkali metal hydroxides (e.g., lithium hydroxide, sodium hydroxide, potassium hydroxide, and cesium hydroxide), and like inorganic bases. Examples of organic base salts include salts of tri(lower)alkylamines (e.g., trimethylamine, triethylamine, and N-ethyldiisopropylamine), pyridine, quinoline, piperidine, imidazole, picoline, dimethylaminopyridine, dimethylaniline, N-(lower)alkyl-morpholines (e.g., N-methylmorpholine), 1,5-diazabicyclo[4.3.0]nonene-5 (DBN), 1,8-diazabicyclo[5.4.0]undecene-7 (DBU), 1,4-diazabicyclo[2.2.2]octane (DABCO), and like organic bases. Examples of inorganic acid salts include hydrochloric acid salts, hydrobromic

acid salts, hydroiodic acid salts, sulfuric acid salts, nitric acid salts, phosphoric acid salts, and the like. Examples of organic acid salts include formic acid salts, acetic acid salts, propionic acid salts, oxalic acid salts, malonic acid salts, succinic acid salts, fumaric acid salts, maleic acid salts, lactic acid salts, malic acid salts, citric acid salts, tartaric acid salts, carbonic acid salts, picric acid salts, methanesulfonic acid salts, ethanesulfonic acid salts, p-toluenesulfonic acid salts, glutamic acid salts, benzoic acid salts, and the like. Among these, hydrochloric acid salts, sulfuric acid salts, fumaric acid salts, phosphoric acid salts, citric acid salts, and tartaric acid salts are preferable.

[0016]

Examples of salts of compound (I) include anhydrides, solvates with a solvent (e.g., hydrate, methanolate, ethanolate, and acetonitrilate), various crystal forms of anhydrides and solvates, and mixtures thereof. Compound (I) or a salt thereof also includes isomers such as geometric isomers, stereoisomers, and optical isomers.

[0017]

The salt of compound (I) can be a pharmaceutically acceptable co-crystal salt. The term "co-crystal" or "co-crystal salt" as used herein means a crystalline material composed of two or more unique solids at room temperature that are different in physical characteristics (such as structure, melting point, and heat of fusion). Co-crystals and co-crystal salts can be produced by known co-crystallization methods.

[0018]

The oral pharmaceutical composition according to the present disclosure is designed as a dosage form suitable for releasing a salt of compound (I) at a uniform rate over a long period of time; and preferably designed as a dosage form suitable for maintaining a constant dissolution concentration, even in the lower part of the gastrointestinal tract. More specifically, the oral pharmaceutical composition is designed as a controlled release oral pharmaceutical composition.

[0019]

The dissolution rate and sustained release time of a salt of compound (1) from the oral pharmaceutical composition can be obtained by measuring the dissolution rate and sustained release time of the salt of compound (I) according to the second method (paddle method) of the dissolution test of the Japanese Pharmacopoeia using, as a test solution, a buffer of pH 5.0 or less that achieves sink conditions (specifically, a 0.05 mol/L acetate buffer (pH 4.3, acetic acid, sodium acetate)).

[0020]

The "dissolution rate" refers to the ratio of the dissolved salt of compound (I) to the total amount of the salt of compound (I) contained in the oral pharmaceutical composition. Therefore, the dissolution rate can be paraphrased as the ratio of dissolved compound (I) to the total amount of compound (I) contained in the oral pharmaceutical composition. The "sustained release time" means the time from the start of measurement of the dissolution test until the final dissolution rate has been reached. The "final dissolution rate" means the dissolution rate when a plateau is reached in the dissolution test, and the "final dissolution amount" means the amount of dissolution (elution) when the final dissolution rate is reached in the dissolution test. In the dissolution test, when the dissolution rate at a certain point of time (the reference point of time) is compared with the dissolution rate two hours after the reference point of time, and if the dissolution rate two hours after the reference point of time falls within the range of the dissolution rate at the reference point of time ± 1% (preferably, when the dissolution rate more than two hours after the reference point of time is compared with the dissolution rate at a certain point of time (the reference point of time) and if the dissolution rate more than two hours after the reference point of time falls within the range of the dissolution rate at the reference point of time ± 1%), a plateau can be considered to be reached at the reference point of time that is the shortest in time from the start of the test. However, the dissolution rate at the reference point of

time should be more than 20% (in other words, when the dissolution rate is not more than 20%, it is not considered to be a plateau).

[0021]

The sustained release time is preferably 5 hours or more. The sustained release time is preferably 30 hours or less. More preferably, the sustained release time is 5 to 30 hours. The upper or lower limit of the range of the sustained release time is, for example, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, or 29 hours. The sustained release time is, for example, even more preferably 10 to 24 hours, and still even more preferably 15 to 24 hours.

[0022]

The final dissolution amount of the oral pharmaceutical composition according to the present disclosure is preferably 80 mass% or more of the total amount of the salt of compound (I) contained in the oral pharmaceutical composition (typically, the oral pharmaceutical formulation). More preferably, the final dissolution amount is 81, 82, 83, 84, 84, 85, 85, 86, 87, 88, 89, or 90 mass% or more.

[0023]

Whether a constant dissolution concentration is maintained in the lower part of the gastrointestinal tract can be evaluated by measuring the supersaturated dissolution concentration profile of the salt of compound (I) per dissolution time using as a test liquid a phosphate buffer of around pH 7, which simulates the lower part of the gastrointestinal tract, according to the second method (paddle method) of the dissolution test of the Japanese Pharmacopoeia.

[0024]

In achieving "sustained release," a rise in initial dissolution of the salt of compound (I) from the composition may be achieved immediately after the start of the dissolution test, or a certain amount of time (for example, 1 to 3 hours) after the start of the measurement. However, it is undesirable for it to take more than 5 hours until the amount of dissolution becomes 5 mass% or more of the final dissolution amount.

[0025]

The "supersaturated dissolution profile" can be evaluated by quantifying, over time, the concentration of the drug temporarily dissolved at a solubility level higher than that of compound (I) in the paddle method dissolution test using the above phosphate buffer solution of around pH 7 (test liquid that simulates the lower part of the gastrointestinal tract). A preferred supersaturated dissolution profile is a profile that reaches a peak of the dissolution rate at a point of time between 4 hours to 18 hours after the start of the dissolution test. Further, the peak is preferably 1 or 1.5 μg/mL or more, more preferably 2, 2.5, or 3 μg/mL or more, and even more preferably 3.5, 4, 4.5, 5, 5.5, or 6 μg/mL or more, in terms of compound (I) (free base). A higher supersaturated concentration contributes more to absorption in the lower part of the gastrointestinal tract, and is thus expected to increase BA (bioavailability) and reduce PTF (Peak Trough Ratio). Such a BA enhancement or PTF reduction makes it easier to fit to the PK (pharmacokinetics) target range.

[0026]

The mode in which a salt of compound (I) is released from the oral pharmaceutical composition at a uniform rate over a long period of time is not particularly limited, and can be achieved by various techniques known in the field of sustained release formulations. Preferable sustained release approaches are those using, for example, a diffusion-controlled composition, a dissolution-controlled composition, or an osmotic pump controlled release composition. Among these, more preferable sustained release approaches are, for example, an osmotic pump controlled release (especially an osmotic controlled release oral delivery system: OROS) composition, and a hydrogel sustained release composition. Such an oral pharmaceutical composition is preferably an oral solid pharmaceutical composition (in particular, a solid formulation) from the viewpoint of being easy to handle.

[0027]

The oral pharmaceutical composition of the present

disclosure preferably further contains an additive containing an ion in common with a salt of compound (I). For example, when the salt of compound (I) is a fumaric acid salt, examples of additives containing an ion in common with the salt include fumaric acid, monosodium fumarate, disodium fumarate, and the like. In this case, the ion in common with the salt is a fumarate ion. A person skilled in the art would be able to understand what ion is in common with the salt of compound (I) in accordance with the type of salt of compound (I) used, and use an additive containing the ion in common with the salt. Examples of such additives include, but are not limited to, inorganic salts, inorganic acids, organic salts, and organic acids, each containing an ion in common with the salt of compound (I). Examples of inorganic salts include sodium chloride, sodium hydrogen carbonate, sodium carbonate, sodium phosphate (trisodium phosphate), potassium phosphate (tripotassium phosphate), sodium hydrogen phosphate (sodium dihydrogen phosphate, disodium hydrogen phosphate), potassium hydrogen phosphate (potassium dihydrogen phosphate, dipotassium hydrogen phosphate), potassium chloride, lithium chloride, magnesium sulfate, magnesium chloride, potassium sulfate, sodium sulfate, sodium hydrogen sulfite, potassium hydrogen sulfite, lithium sulfate, acidic potassium phosphate, and the like. Examples of inorganic acids include acids that form the above-mentioned inorganic salts. Examples of organic salts include sodium fumarate (disodium fumarate), sodium hydrogen fumarate (monosodium fumarate), sodium hydrogen tartrate, potassium hydrogen tartrate, sodium tartrate, sodium potassium tartrate, sodium malate (disodium malate), sodium hydrogen succinate, sodium succinate (disodium succinate), sodium hydrogen maleate, sodium maleate (disodium maleate), sodium hydrogen citrate (sodium dihydrogen citrate, disodium hydrogen citrate), sodium citrate (trisodium citrate), and the like. Examples of organic acids include acids that form the above-mentioned organic salts. These may be anhydrides or solvates (such as hydrates).

[0028]

The oral pharmaceutical composition according to the

present disclosure preferably contains a cellulose-based water-soluble polymer. The cellulose-based water-soluble polymer is preferably contained in a drug-containing composition. The cellulose-based water-soluble polymer that can be preferably used is, for example, a cellulose-based water-soluble polymer known in the pharmaceutical field. For example, a cellulose-based water-soluble polymer having a structure in which some of the hydrogen atoms of OH groups of cellulose are replaced with methyl groups and/or hydroxypropyl groups is preferable. Specific examples of preferable cellulose-based water-soluble polymers include hydroxypropylmethyl cellulose, hydroxypropyl cellulose, methyl cellulose, and the like. Such cellulose-based water-soluble polymers can be used singly, or in a combination of two or more.

[0029]

Next, the present disclosure is described below in more detail with reference to an osmotic pump controlled release composition, which is a preferred oral solid pharmaceutical composition. The osmotic pump controlled release composition in the form of a formulation can be referred to as an osmotic pump formulation.

[0030]

The osmotic pump composition generally has a structure in which a drug and a substance that generates osmotic pressure as necessary (an osmotic agent), such as a salt, are surrounded by a semipermeable membrane; and the semipermeable membrane has pores through which the drug can be released. A fluid (e.g., water) enters through the semipermeable membrane according to the osmotic pressure and dissolves the drug and osmotic agent therein, which increases the osmotic pressure gradient across the semipermeable membrane and causes additional fluid to flow into the semipermeable membrane, thereby further dissolving and releasing the drug. The osmotic pump composition is advantageous in that since the release rate of the drug does not depend on the pH of the environment, even if the composition passes through the gastrointestinal tract and encounters a significantly different pH environment, the composition can

sustainably release the drug at a constant rate according to the osmotic pressure over a long period of time.

[0031]

For one embodiment of an oral pharmaceutical composition of the present disclosure, which is an osmotic pump composition, an explanation is provided below with reference to the drawings. In Fig. 12, the osmotic pump composition 1 (hereinafter sometimes referred to simply as formulation 1) includes a wall 2 surrounding an internal compartment 5 in which a composition containing a salt of compound (I) is present. The wall 2 has at least one drug release port 3 that communicates the external environment with the internal compartment. The internal compartment 5 contains a bilayered compressed core comprising a drug layer 6 and a push layer 7. The drug release port 3 is preferably provided in the wall 2 so as to communicate the internal compartment 5 on the drug layer 6 side with the external environment. One or more drug release ports 3 may be provided. For example, the formulation may have two or three drug release ports 3.

[0032]

The wall 2 is a semi-permeable membrane through which water and external liquids permeate, but through which drugs, osmotic agents, and the like do not permeate. The drug layer 6 comprises a salt of compound (I) in the form of a mixture with one or more additives. The push layer 7 does not comprise any salts of compound (I), and comprises an osmotic agent and a highly swelling polymer. The osmotic agent refers to an ingredient that is water-soluble and that raises the concentration of an electrolyte in a pharmaceutical formulation, such as an inorganic salt and a saccharide and/or a sugar alcohol. The highly swellable polymer means a polymer that absorbs a liquid and swells (a polymer having a relatively high molecular weight is preferable). The highly swellable polymer absorbs a liquid and swells, whereby a salt of compound (I) is released through the release port 3. The drug layer 6 and the push layer 7 may further contain additives, such as a hydrophilic polymer, an osmagent, a hydration promoter, a pH

regulator, a binder, a fluidizer, an antioxidant, a lubricant, and a pigment.

[0033]

In an osmotic pump composition, after oral intake, a liquid, such as water, permeates the semi-permeable membrane and is absorbed into the composition. Due to the generated osmotic pressure effect, a salt of compound (I) in the drug layer becomes releasable, and a highly swellable polymer in the push layer swells simultaneously. As the body fluid continues to permeate the internal compartment, a releasable salt of compound (I) can be released through the drug release port 3. The release of the salt of compound (I) results in further permeation of the body fluid and further swelling of the push layer to achieve a sustained release of the salt of compound (I).

[0034]

Preferably, the semi-permeable membrane used is highly permeable to external liquids, such as water and biological fluids, but is substantially impermeable to a salt of compound (I), osmagents, highly swellable polymers, etc. Preferably, the semipermeable membrane is substantially non-erodible, and insoluble *in vivo*.

[0035]

Examples of typical polymers to be used to form a semipermeable film include semipermeable monopolymers, semipermeable copolymers, and the like. Examples include cellulose-based polymers such as cellulose ester, cellulose ether, and cellulose ester-ether. Specific examples include cellulose acylate, cellulose diacylate, cellulose triacylate, cellulose acetate, cellulose diacetate, cellulose triacetate, mono-, di- and tri-cellulose alkanylate, mono-, di- and tri-alkenylate, mono-, di- and tri-alloylate, and the like. Among them, cellulose acetate is preferable. The semipermeable membrane can be prepared from such a polymer by a known method.

[0036]

In addition to the above, other examples of the semipermeable polymer for forming a semipermeable membrane of the

osmotic pump composition include the following: cellulose acetaldehyde dimethyl acetate; cellulose acetate ethyl carbamate; cellulose acetate methyl carbamate; cellulose dimethylaminoacetate; semipermeable polyurethane; semipermeable sulfonated polystyrene; crosslinked selectively semipermeable polymers formed by co-precipitation from anion and cation, as disclosed in U.S. Patents Nos. 3,173,876, 3,276,586, 3,541,005, 3,541,006, and 3,546,142; semipermeable polymers, as disclosed in U.S. Patent No. 3,133,132; semipermeable polystyrene derivatives; semipermeable poly(sodium styrene sulfonate); semipermeable poly(vinyl benzyltrimethylammonium chloride); and a semipermeable polymer showing a liquid permeability of 10^{-5} to 10^{-2} (cc ml/cm hr atm) in terms of a hydrostatic pressure difference or an osmotic pressure difference per atmosphere upon permeation through a semipermeable wall.

[0037]

Such exemplified polymers for use to form the semipermeable membrane may be used singly, or in a combination of two or more.

[0038]

The semipermeable membrane may contain a flux-regulating agent. The flux-regulating agent means a substance added to assist in regulating the fluid permeability or the fluid volume through the semipermeable membrane. The flux-regulating agent includes a substance that enhances the flux (hereinafter referred to as a flux-enhancing agent) or a substance that decreases the flux (hereinafter referred to as a flux-decreasing agent). The flux-enhancing agent is essentially hydrophilic, while the flux-decreasing agent is essentially hydrophobic.

[0039]

Examples of the flux-regulating agent include polyhydric alcohols, polyalkylene glycols, polyalkylene diols, polyesters of alkylene glycols, and the like.

[0040]

Examples of representative flux-enhancing agents include polyethylene glycols (having an average molecular weight of 190 to

9000, such as polyethylene glycol 300, 400, 600, 1500, 3000, 3350, 4000, 6000, or 8000); low-molecular-weight glycols, such as polypropylene glycol, polybutylene glycol, and polyamylene glycol; polyalkylenediols, such as poly(1,3-propanediol), poly(1,4-butanediol), and poly(1,6-hexanediol); fatty acids, such as 1,3-butylene glycol, 1,4-pentamethylene glycol, and 1,4-hexamethylene glycol; alkylene triols, such as glycerine, 1,2,3-butanetriol, 1,2,4-hexanetriol, and 1,3,6-hexanetriol; esters, such as ethylene glycol dipropionate, ethylene glycol butyrate, butylene glycol dipropionate, and glycerol acetate esters. Preferred flux-enhancing agents include difunctional block copolymer polyoxyalkylene derivatives of propylene glycol known as Pluronics (BASF), and the like.

[0041]

Typical flux-decreasing agents include phthalates substituted with alkyl or alkoxy, or with alkyl and alkoxy groups, such as diethyl phthalate, dimethoxyethyl phthalate, dimethyl phthalate, and [di(2-ethylhexyl)phthalate]; aryl phthalates such as triphenyl phthalate and butyl benzyl phthalate; insoluble salts such as calcium sulfate, barium sulfate, and calcium phosphate; insoluble oxides such as titanium oxide; polymers in the form of, for example, a powder or granules, such as polystyrene, polymethylmethacrylate, polycarbonate, and polysulfone; esters such as citric acid esters esterified with long-chain alkyl groups; inert and water-impermeable fillers; resins compatible with cellulose-based wall forming materials; and the like.

[0042]

Such exemplified flux-regulating agents may be used singly, or in a combination of two or more.

[0043]

The semipermeable membrane may contain other substances, for example, in order to impart flexibility and elongation properties to the semipermeable membrane, to make the semipermeable membrane less brittle, or to give tear strength to the semipermeable membrane. Examples of materials suitably added for such a purpose

include plasticizers. Specific examples include phthalate plasticizers such as dibenzyl phthalate, dihexyl phthalate, butyl octyl phthalate, C_6-C_{11} straight-chain phthalates, diisononyl phthalate, diisodecyl phthalate, and the like. Other examples of plasticizers include non-phthalates such as triacetin, dioctyl azelate, epoxidized tallate, triisoctyl trimellitate, triisononyl trimellitate, sucrose acetate isobutyrate, and epoxidized soybean oil. When a plasticizer such as those mentioned above is present in the semipermeable membrane, the amount of plasticizer is about 0.01 to 30 mass% or more, based on the total amount of all components of the semipermeable membrane.

[0044]

The push layer contains a composition for pushing a salt of compound (I) and is in a layered arrangement in contact with the drug layer, for example, as shown in Fig. 12. As described above, the push layer comprises a highly swellable polymer that absorbs an aqueous liquid or a biological fluid, and swells to extrude a salt of compound (I) through the release port of the formulation. The highly swellable polymer is preferably a swellable hydrophilic polymer that interacts with water or an aqueous biological fluid, and greatly swells or expands; and typically exhibits a 2- to 50-fold volume increase. The highly swellable polymer can be crosslinked or non-crosslinked. In a preferred embodiment, the polymer is preferably at least crosslinked to create an extended polymer network that is too large to exit the formulation. Accordingly, in a preferred embodiment, the swellable composition is retained in the formulation during its effective life span.

[0045]

Examples of highly swellable polymers include poly(alkylene oxide) having a number average molecular weight of 10000 to 15000000, such as polyethylene oxide, and poly(alkali carboxymethylcellulose) having a number average molecular weight of 500000 to 3500000 (wherein the alkali is sodium, potassium, or lithium). Examples of highly swellable polymers further include polymers comprising polymers that form hydrogels, such as Carbopol

(registered trademark), acidic carboxypolymers, acrylic polymers crosslinked with polyallyl sucrose (also known as carboxypolymethylene), and carboxyvinyl polymers having a molecular weight of 250000 to 4000000; Cyanamer (registered trademark) polyacrylamides; crosslinked water-swellable indenemaleic anhydride polymers; Good-rite (registered trademark) polyacrylic acid having a molecular weight of 80000 to 200000; Aqua-Keeps (registered trademark), acrylate polymer polysaccharides composed of condensed glucose units, such as diester crosslinked polygluran; and the like. Polymers that form hydrogels are disclosed in U.S. Patents Nos. 3,865,108, 4,002,173, 4,207,893, etc.

[0046]

Such exemplified highly swellable polymers can be used singly, or in a combination of two or more.

[0047]

The osmagent, sometimes also referred to as an osmotic solute or an osmotically effective agent, may be present in both of the drug layer and the push layer. The osmagent (osmotic pressure regulator) is not particularly limited, insofar as it exhibits an osmotic activity gradient across the semipermeable membrane. Examples thereof include inorganic salts, inorganic acids, organic salts, organic acids, saccharides, sugar alcohols, and the like. Examples of inorganic salts include sodium chloride, sodium hydrogen carbonate, sodium carbonate, sodium phosphate (trisodium phosphate), potassium phosphate (tripotassium phosphate), sodium hydrogen phosphate (sodium dihydrogen phosphate, disodium hydrogen phosphate), potassium hydrogen phosphate (potassium dihydrogen phosphate, dipotassium hydrogen phosphate), potassium chloride, lithium chloride, magnesium sulfate, magnesium chloride, potassium sulfate, sodium sulfate, sodium hydrogen sulfite, potassium hydrogen sulfite, lithium sulfate, acidic potassium phosphate, and the like. Examples of inorganic acids include acids that form the above-mentioned inorganic salts. Examples of organic salts include sodium fumarate (disodium fumarate), sodium hydrogen fumarate (monosodium fumarate), sodium hydrogen tartrate, potassium hydrogen tartrate,

sodium tartrate, sodium potassium tartrate, sodium malate (disodium malate), sodium hydrogen succinate, sodium succinate (disodium succinate), sodium hydrogen maleate, sodium maleate (disodium maleate), sodium hydrogen citrate (sodium dihydrogen citrate, disodium hydrogen citrate), sodium citrate (trisodium citrate), and the like. Examples of organic acids include acids that form the above-mentioned organic salts. Examples of saccharides and sugar alcohols include mannitol, glucose, lactose, fructose, sucrose, sorbitol, xylitol, erythritol, lactose, and the like. These may be anhydrides or solvates (such as hydrates). These can be used singly, or in a combination of two or more.

[0048]

The drug layer preferably contains an additive containing an ion in common with the salt of compound (I). For example, when the salt of compound (I) is a fumarate, examples of additives containing an ion in common include fumaric acid, monosodium fumarate, disodium fumarate, and the like. In this case, the ion in common is a fumarate ion. When the salt of compound (I) is a phosphate, examples of additives containing an ion in common include sodium phosphate (trisodium phosphate), potassium phosphate (tripotassium phosphate), sodium hydrogen phosphate (sodium dihydrogen phosphate, disodium hydrogen phosphate), potassium hydrogen phosphate (potassium dihydrogen phosphate, dipotassium hydrogen phosphate), and the like. In this case, the ion in common is a phosphate ion. When the salt of compound (I) is a hydrochloride, examples of additives containing an ion in common include sodium chloride, potassium chloride, lithium chloride, magnesium chloride, and the like. In this case, the ion in common is a chloride ion. When the salt of compound (I) is a sulfate, examples of additives containing an ion in common include magnesium sulfate, potassium sulfate, sodium sulfate, lithium sulfate, and the like. In this case, the ion in common is a sulfate ion. When the salt of compound (I) is a citrate, examples of additives containing an ion in common include sodium hydrogen citrate (sodium dihydrogen citrate, disodium hydrogen citrate), sodium citrate (trisodium

citrate), and the like. In this case, the ion in common is a citrate ion. When the salt of compound (I) is a tartrate, examples of additives containing an ion in common include sodium hydrogen tartrate, potassium hydrogen tartrate, sodium tartrate, sodium potassium tartrate, and the like. In this case, the ion in common is a tartrate ion. A person skilled in the art would understand, according to the type of salt of compound (I) used, what ion is in common with the salt of compound (I), and would be able to use an additive containing the ion in common. Other examples of additives containing an ion in common with the salt of compound (I) that can be used are as described above.

[0049]

Examples of solvents suitable for use in manufacturing the osmotic pump composition or components thereof include aqueous or inert organic solvents that do not adversely affect substances used in the composition. Examples of such solvents include at least one member selected from the group consisting of aqueous solvents, alcohols, ketones, esters, ethers, aliphatic hydrocarbons, halogenated solvents, cycloaliphatic, aromatic, or heterocyclic solvents, and mixtures thereof.

[0050]

Examples of representative solvents include acetone, diacetone alcohol, methanol, ethanol, isopropanol, butyl alcohol, methyl acetate, ethyl acetate, isopropyl acetate, n-butyl acetate, methyl isobutyl ketone, methyl propyl ketone, n-hexane, n-heptane, ethylene glycol monoethyl ether, ethylene glycol monoethyl acetate, methylene dichloride, ethylene dichloride, propylene dichloride, carbon tetrachloride, nitroethane, nitropropane, tetrachloroethane, ethyl ether, isopropyl ether, cyclohexane, cyclooctane, benzene, toluene, naphtha, 1,4-dioxane, tetrahydrofuran, diglyme, water, an aqueous solvent containing an inorganic salt, such as sodium chloride or calcium chloride, and mixtures thereof (such as a mixture of acetone and water, a mixture of acetone and methanol, a mixture of acetone and ethyl alcohol, a mixture of methylene dichloride and methanol, and a mixture of ethylene dichloride and

methanol); and the like.

[0051]

The drug layer comprises a therapeutically effective amount of a salt of compound (I) and a carrier. The carrier can comprise a hydrophilic polymer. The hydrophilic polymer can provide, for example, hydrophilic polymer particles in the pharmaceutical composition that contribute to a uniform release rate and a controlled release pattern of the salt of compound (I). Examples of these polymers include poly(alkylene oxide) having a number average molecular weight of 100000 to 750000, such as poly(ethylene oxide), poly(methylene oxide), poly(butylene oxide), and poly(hexylene oxide); and poly(carboxymethyl cellulose) having a number average molecular weight of 40000 to 400000, such as poly(alkali carboxymethylcellulose), poly(sodium carboxymethylcellulose), poly(potassium carboxymethylcellulose), poly(lithium carboxymethylcellulose), and the like. The pharmaceutical composition may contain hydroxypropylalkyl cellulose having a number average molecular weight of 9200 to 125000, such as hydroxypropylethyl cellulose, hydroxypropylmethyl cellulose, hydroxypropylbutyl cellulose, and hydroxypropylpentyl cellulose, to improve release properties of the composition; and poly(vinylpyrrolidone) having a number average molecular weight of 7000 to 75000, to improve flow properties of the composition. Among these polymers, poly(ethylene oxide) having a number average molecular weight of 100000 to 300000 is preferable.

[0052]

Other carriers that can be present in the drug layer include carbohydrates that exhibit sufficient osmotic activity when used alone or with another osmagent. Such carbohydrates include monosaccharides, disaccharides, and polysaccharides. Representative examples include saccharides such as maltodextrin (i.e., a glucose polymer produced by hydrolysis of corn starch), lactose, glucose, raffinose, sucrose, mannitol, and sorbitol. Preferred maltodextrins are those having a dextrose equivalence (DE) of 20 or less, preferably a DE of about 4 to about 20, and more preferably a DE of

9 to 20. The use of a maltodextrin having a DE of 9 to 12 is preferable. Carbohydrates (preferably maltodextrin) are preferable because they are usable in the drug layer without adding another osmagent, and impart long-term stability to the composition.

[0053]

The drug layer is, for example, a homogeneous dry composition formed by compression of a carrier and a drug. The drug layer may be formed from particles of a milled drug and an added polymer. Granulation can be carried out using known techniques, such as granulation, spray drying, sieving, lyophilization, crushing, grinding, shredding, and the like. Such granulation can be carried out using devices such as a high-speed stirring granulator, an extrusion granulator, a fluidized bed granulator, and a roller compactor.

[0054]

The drug layer may contain one or more surfactants, and one or more disintegrating agents. Examples of such surfactants include surfactants having an HLB value of about 10 to 25 (specifically, polyethylene glycol 400 monostearate, polyoxyethylene-4-sorbitan monolaurate, polyoxyethylene-20-sorbitan monooleate, polyoxyethylene-20-sorbitan monopalmitate, polyoxyethylene-20-monolaurate, polyoxyethylene-40-stearate, sodium oleate, and the like). Examples of disintegrants include starches, clays, celluloses, algins, gums, crosslinked starches, celluloses, polymers, and the like. Preferable disintegrants include corn starch, potato starch, croscarmellose, crospovidone, sodium starch glycolate, Veegum HV, methylcellulose, agar, bentonite, carboxymethylcellulose, alginic acid, guar gum, and the like.

[0055]

The drug layer may further contain light anhydrous silicic acid and the like.

[0056]

The semipermeable membrane can be formed on the surface of the bilayered compressed core, for example, by pan coating. More specifically, the semipermeable membrane can be formed by spraying

the composition for forming a semipermeable membrane over the surface of the compressed bilayered core comprising a drug layer and a push layer tumbling in a rotating pan. Coating techniques other than pan coating can also be used to coat the compression core. For example, the semipermeable membrane may be formed by a technique using an air-suspension procedure. This procedure consists of suspending the compressed core in a current of air and the semipermeable membrane-forming composition, and tumbling it until a semipermeable membrane is formed on the core. The air-suspension procedure is well-suited for independently forming the semipermeable membrane. Such an air-suspension technique is known (e.g., U.S. Patent No. 2,799,241). It is also possible to use a Wurster (registered trademark) air-suspension coater, or an AeromaticR (registered trademark) air-suspension coater.

[0057]

After coating with the semi-permeable membrane, the semipermeable membrane is dried, for example, in a forced-air furnace, or in a furnace with a controlled temperature and humidity, to thereby remove the solvent. Drying conditions can be suitably selected in consideration of available equipment, ambient conditions, solvents, coating materials, coating thickness, etc.

[0058]

The oral pharmaceutical composition according to the present disclosure can be produced by utilizing a known formulation technique. For example, the oral pharmaceutical composition can be manufactured by existing wet granulation techniques or dry granulation techniques. More specifically, for example, in the case of wet granulation techniques, an organic solvent, such as a denatured anhydrous alcohol, is used as a granulating solution; and a drug and an additive are mixed in a granulator and continuously granulated using the solvent, to thereby obtain granules. The granulating solution is added until a wet mixture is formed, and the wet mass mixture is passed through a pre-installed screen on an oven tray. The mixture is then dried in a forced-air oven. Another granulation method is an operation of granulating powder components

of each layer in a fluidized bed granulator. After the powder components are dry-mixed in a granulator, the granulating liquid is sprayed onto the powder. The coated powder is dried in a granulator. The dry granules obtained by these methods are sized in a granulator with a crushing mechanism. A lubricant, such as magnesium stearate, is then added and mixed into granules using a blender (e.g., a V-type blender, or a transportable blender (tote blender)). The composition thus obtained is layered by pressing using, for example, a Manesty (registered trademark) press or a Korsch LCT press. To produce a two-layered core, the drug-containing layer is first pressed; and then a wet mixture of the push layer, which has been produced by the wet granulation technique in a similar manner, is pressed against the drug-containing layer. The compressed bilayered core is coated with a water-soluble polymer, if necessary, and then coated with a semipermeable membrane material as described above. One or more outlets (apertures) are provided at the end of the drug layer of the composition. If necessary, a water-soluble overcoat may be applied, and the overcoat coating may be colored or transparent. [0059]

Further, for example, when a dry granulation technique is used as an alternative method, a premixed composition is formed into a layered product using a roller compression molding machine, and the layered product is crushed into granules and sized using a screened grinder with a crushing mechanism. A lubricant, such as magnesium stearate, was added to the sized granules in the same manner as above, mixed into granules using a blender, and pressed in the same manner as in the production method described above. [0060]

The osmotic pump composition is provided with at least one release port. The release port is provided during manufacture of the composition or during drug delivery by the composition in a liquid environment at the time of use. The expression “release port” includes the meaning of, for example, passages, openings, orifices, and lumens (bores). This expression also includes apertures formed by erosion, dissolution, or leaching of a substance or a polymer

from the outer wall. Such a substance or polymer includes, for example, erodible poly(glycolic acid) or poly(lactic acid) in the semipermeable membrane; gelatinous filaments; water-removable poly(vinyl alcohol); and leachable compounds such as fluid-removable aperture-forming substances selected from the group consisting of inorganic salts, organic salts, oxides, and carbohydrates. The release port can be formed, for example, by leaching at least one substance selected from the group consisting of sorbitol, mannitol, lactose, fructose, maltitol, maltose, dextrin, glucose, mannose, galactose, talose, sodium chloride, potassium chloride, and sodium citrate to provide orifices having a pore size suitable for uniform release of a drug. The release port can have any shape, such as a round, rectangular, square, or elliptical shape, as long as the drug can be released from the composition at a uniform rate. The osmotic pump composition can have one or more release ports provided at regular intervals. The orifice size of the release port is not particularly limited, as long as the release of the drug can be controlled in cooperation with the compression core. Preferably, the orifice size of the release port is 0.1 mm to 3 mm. To form a release port, for example, a technique of drilling through the semipermeable membrane, such as mechanical drilling and laser drilling, can be used. Devices for forming such a release port are known (e.g., U.S. Patent No. 3,916,899 and U.S. Patent No. 4,088,864).

[0061]

The amount of the salt of compound (I) in the oral pharmaceutical composition is, for example, in the range of less than about 1 mg to about 200 mg, or more, per dosage form, in terms of the weight of the free base. For example, the drug layer of the osmotic pump composition described below in the Examples contains compound (I) in an amount of 30 mg (in terms of free base). The osmotic pump composition has a T_{90} value of about 10 hours or more. The salt of compound (I) begins to be released at a uniform rate within about 3 to 4 hours after administration, and the release at a uniform rate continues over a long period of at least about 12

hours. The drug release thereafter further continues for several hours until the formulation is consumed.

[0062]

The oral pharmaceutical compositions according to the present disclosure preferably releases the drug at a relatively uniform release rate over a long period of time. When administered to a patient, the oral pharmaceutical composition according to the present disclosure provides blood plasma drug concentrations in the patient that are less fluctuating over a long period of time than those obtained with conventional pharmaceutical agents (e.g., immediate-release formulations). When the oral pharmaceutical composition according to the present disclosure is administered, a peak occurs at a time later than the occurrence of a peak plasma concentration in a steady state after administration of conventional pharmaceutical agents (e.g., immediate-release formulations), and the peak is smaller than the peak observed after administration of conventional pharmaceutical agents; accordingly, the composition can provide a therapeutically effective average steady-state blood concentration.

[0063]

The present disclosure includes a method of treating disease states and conditions that are responsive to treatment with compound (I) by orally administering the oral pharmaceutical composition according to the present disclosure to a patient. This method is practiced with a formulation that is suitable for the release of compound (I) at a uniform release rate over a period of at least about 4 hours, preferably 5 to 30 hours, more preferably 10 to 24 hours, and even more preferably 15 to 24 hours.

[0064]

For the treatment of schizophrenia, the practice of the foregoing method is preferable for the purpose of orally administering the oral pharmaceutical composition according to the present disclosure to a patient at a frequency of less than once a day. Other disease states and conditions, which may be clinically diagnosed as symptoms of schizophrenia, can be treated with the

controlled release oral pharmaceutical composition according to the present disclosure.

[0065]

Although this is not limitative, the oral pharmaceutical composition according to the present disclosure preferably maintains a blood concentration of compound (I) in a steady state in the range of, for example, 15 ng/mL to 400 ng/mL, or 50 ng/ml to 300 ng/mL, for 1 week, when orally administered to a human (in particular, a human adult).

Ordinary tablets (non-release controlled formulations) containing compound (I) in the form of 0.5 mg, 1 mg, and 2 mg tablets are already commercially available in many countries, including Japan, the U.S., and Europe. Ordinary tablets have been confirmed to be safe and effective against CNS diseases, such as schizophrenia, in clinical trials; and detailed pharmacokinetic analysis has been performed. In consideration of such information on ordinary tablets, it can be understood that any oral pharmaceutical composition capable of maintaining a blood concentration of compound (I) in a steady state in the range of, for example, 15 ng/mL to 400 ng/mL, or 50 ng/mL to 300 ng/mL, when administered to a human, can be used to prevent or treat a CNS disease, such as schizophrenia, in the same manner as ordinary tablets that are already commercially available.

Accordingly, the oral pharmaceutical composition according to the present disclosure can be orally administered less frequently than once daily; for example, it can be orally administered once a week. The oral pharmaceutical composition according to the present disclosure may be administered in one tablet at a time, or two or tablets at a time; for example, it may be administered in two tablets, three tablets, four tablets, or five tablets at a time. Persons skilled in the art would be able to appropriately determine the dose of the oral pharmaceutical composition according to the present disclosure to achieve the above blood concentration based on, for example, pharmacokinetic information on the ordinary tablets; and evaluations based on the single-dose administration

protocol and multiple-dose administration protocol for the oral pharmaceutical composition according to the present disclosure. For example, the dosage per dose can be about 5 to 60 mg, about 10 to 60 mg, about 20 to 60 mg, or about 45 to 60 mg, in terms of the weight of the free base of compound (I).

[0066]

As described above, among the oral pharmaceutical compositions according to the present disclosure, one particularly preferable embodiment is an oral solid pharmaceutical formulation of an osmotic pump controlled release system. Of the oral solid pharmaceutical formulations of an osmotic pump controlled release system, particularly preferable embodiments are described below in more detail. Note that the following description may partially overlap with the above description. The following description does not prevent application of the above description.

[0067]

The oral solid pharmaceutical formulation of an osmotic pump controlled release system preferably has a structure in which a core formulation formed by laminating a drug layer and a push layer is coated with a semipermeable membrane, and the drug layer comprises a salt of compound (I). One embodiment of the formulation includes the formulation shown in Fig. 12.

[0068]

The mass ratio of the drug layer to the push layer is, for example, about 20 to 125 parts by mass of the push layer per 100 parts by mass of the drug layer. The upper limit or the lower limit of this range is, for example, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 105, 110, 115, or 120 parts by mass. The range may be, for example, 35 to 100 parts by mass, or 40 to 60 parts by mass.

The mass ratio of the drug layer to the push layer can be, for example, in the range of about 0.8 to 5. The upper limit or the lower limit of the mass ratio can be, for example, 0.9, 1, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2, 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, 2.9, 3, 3.1, 3.2, 3.3, 3.4, 3.5, 3.6, 3.7, 3.8, 3.9, 4,

4.1, 4.2, 4.3, 4.4, 4.5, 4.6, 4.7, 4.8, or 4.9. For example, the mass ratio of the drug layer to the push layer can be in the range of about 1 to 4, or about 2 to 3. More specifically, the mass ratio can be 2.0, 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, 2.9, or 3.0.

[0069]

The salt of compound (I) is not particularly limited, as long as it is a pharmaceutically acceptable salt. Examples include the above-mentioned various metal salts, inorganic base salts, organic base salts, inorganic acid salts, organic acid salts, and the like. The salt is preferably, for example, a fumaric acid salt, a hydrochloric acid salt, a sulfuric acid salt, or the like, and particularly preferably a fumaric acid salt.

[0070]

The salt includes solvates of salts, and may be present in the form of a solvate in the pharmaceutical formulation. Examples of solvates include hydrate, methanol solvate, ethanol solvate, and the like. The solvate may be a monosolvate, disolvate, trisolvate, or the like. For example, the solvate may be a monohydrate, a dihydrate, a trihydrate, or the like. A particularly preferable example of such a solvate of a salt is, for example, fumarate monohydrate.

[0071]

The amount of the salt of compound (I) in the drug layer can be, for example, in the range of about 5 to 200 mg in terms of the weight of the free base. The upper limit or the lower limit of this range is, for example, 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 105, 110, 115, 120, 125, 130, 135, 140, 145, 150, 155, 160, 165, 170, 175, 180, 185, 190, or 195 mg. The amount of the salt of compound (I) may be, for example, in the range of about 5 to 60 mg, about 15 to 150 mg, or about 20 to 100 mg, in terms of the weight of the free base of compound (I).

[0072]

The amount of the salt of compound (I) contained in the drug layer can be, for example, about 1 to 35 mass% of the drug layer. The upper limit or the lower limit of the range is, for

example, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, or 34 mass%. The range may be, for example, about 2 to 30 mass%, or about 5 to 20 mass%.

[0073]

In addition to the salt, the drug layer may contain additives, such as an osmagent and a hydrophilic polymer.

[0074]

The osmagent contained in the drug layer is not particularly limited, as long as it exhibits an osmotic pressure gradient through the semipermeable membrane. Examples include inorganic salts, inorganic acids, organic salts, organic acids, saccharides, sugar alcohols, and the like. Examples of inorganic salts include sodium chloride, sodium hydrogen carbonate, sodium carbonate, sodium phosphate (trisodium phosphate), potassium phosphate (tripotassium phosphate), sodium hydrogen phosphate (sodium dihydrogen phosphate, disodium hydrogen phosphate), potassium hydrogen phosphate (potassium dihydrogen phosphate, dipotassium hydrogen phosphate), potassium chloride, lithium chloride, magnesium sulfate, magnesium chloride, potassium sulfate, sodium sulfate, sodium hydrogen sulfite, potassium hydrogen sulfite, lithium sulfate, acidic potassium phosphate, and the like. Examples of inorganic acids include acids that form the above-mentioned inorganic salts. Examples of organic salts include sodium fumarate (disodium fumarate), sodium hydrogen fumarate (monosodium fumarate), sodium hydrogen tartrate, potassium hydrogen tartrate, sodium tartrate, sodium potassium tartrate, sodium malate (disodium malate), sodium hydrogen succinate, sodium succinate (disodium succinate), sodium hydrogen maleate, sodium maleate (disodium maleate), sodium hydrogen citrate (sodium dihydrogen citrate, disodium hydrogen citrate), sodium citrate (trisodium citrate), and the like. Examples of organic acids include acids that form the above-mentioned organic salts. Examples of sugars and sugar alcohols include mannitol, glucose, lactose, fructose, sucrose, sorbitol, xylitol, erythritol, lactose, and the like. These may be anhydrides

or solvates (such as hydrates). These can be used alone, or in a combination of two or more. The osmagent contained in the drug layer preferably contains an ion in common with the salt of compound (I). For example, when the salt is a fumarate, examples of the osmagent containing an ion in common with the fumarate include fumaric acid, monosodium fumarate, disodium fumarate, and the like. The osmagent can be used singly, or in a combination of two or more.

[0075]

The content of the osmagent in the drug layer is, for example, about 1 to 50 mass%, based on the weight of the drug layer. The upper limit or the lower limit of the range is, for example, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, or 49 mass%. For example, the range may be 10 to 38 mass% or 15 to 35 mass%.

[0076]

Examples of hydrophilic polymers contained in the drug layer include polyethylene oxide, polyethylene glycol, and the like. Preferably, the polyethylene oxide is a low-viscosity polyethylene oxide. More specifically, the polyethylene oxide is preferably a polyethylene oxide having an average molecular weight of about 100000 to 300000, and more preferably a polyoxyethylene oxide having an average molecular weight of about 150000 to 250000, or 180000 to 220000. Preferably, the polyethylene glycol is, for example, one in which about 4000 to 8000, preferably about 4500 to 7500, about 5000 to 7000, or about 5500 to 6500 ethylene oxide units are polymerized on average. In order to inhibit recrystallization of the drug in the formulation, the drug layer may contain, as a hydrophilic polymer, a cellulose-based water-soluble polymer such as methyl cellulose, hydroxypropyl cellulose, hydroxypropylalkyl cellulose (e.g., hydroxypropyl ethylcellulose, hydroxypropyl methylcellulose, hydroxypropyl butylcellulose, and hydroxypropylpentyl cellulose), polyvinyl alcohol, a polyvinyl alcohol-polyethylene glycol graft copolymer, polyvinylpyrrolidone, copolyvidone, and the like. The hydroxypropylalkyl cellulose is particularly preferably

hydroxypropylmethyl cellulose. The hydroxypropyl methylcellulose preferably has a methoxy group content of, for example, about 16 to 30%, and more preferably about 27 to 30%. Such hydrophilic polymers can be used singly, or in a combination with two or more types.

As described above, the oral pharmaceutical composition according to the present disclosure preferably comprises a drug-containing composition containing a cellulose water-soluble polymer. Accordingly, the drug layer preferably contains a cellulose-based water-soluble polymer as a hydrophilic polymer.

[0077]

The hydrophilic polymer content of the drug layer is, for example, about 5 to 94 mass% of the drug layer. The upper or lower limit of the range are, for example, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 84, 85, 86, 87, 88, 89, 90, 91, 92, or 93 mass%. For example, the range may be from 20 to 90 mass%.

[0078]

When the drug-containing composition particularly contains a cellulose-based water-soluble polymer, the content of the cellulose-based water-soluble polymer in the drug layer is, for example, about 5 to 40 mass%, or about 10 to 30 mass%, or about 10 to 20 mass%, based on the weight of the drug layer.

[0079]

When the drug layer particularly contains (i) polyethylene oxide and (ii) at least one member selected from the group consisting of hydroxypropyl cellulose, methyl cellulose, hydroxypropylalkyl cellulose, polyvinyl alcohol, a polyvinyl alcohol-polyethylene glycol graft copolymer, polyvinylpyrrolidone, and copolyvidone at the same time as hydrophilic polymers, the content of component (i) can be 10 to 60 mass% and the content of component (ii) can be about 5 to 40 mass%, based on the weight of the drug layer.

[0080]

The drug layer may also contain other additives. Examples of such additives include lubricants, fluidizers, and the like. Examples of preferable lubricants include magnesium stearate. Examples of preferable fluidizers include silicon dioxide (in particular, light anhydrous silicic acid).

[0081]

The drug layer contains a lubricant (in particular, magnesium stearate), for example, in an amount of about 0.1 to 5 mass% or about 0.2 to 3 mass%, based on the weight of the drug layer. The drug layer can contain a fluidizer (in particular, silicon dioxide) in an amount of, for example, 0.1 to 5 mass% or about 0.1 to 3 mass%, based on the weight of the drug layer.

[0082]

The push layer also comprises a component for extruding a salt of compound (I). Examples of the component include a highly swellable polymer. Examples of highly swellable polymers include polyalkylene oxide, and more specifically include polyethylene oxide. Preferably, the polyethylene oxide contained in the push layer is a high-viscosity polyethylene oxide; and is more specifically, for example, a polyethylene oxide having an average molecular weight of, for example, about 3000000 to 7000000, about 4000000 to 7000000, or about 4000000 to 6000000.

[0083]

The amount of the highly swellable polymer in the push layer may vary depending on factors, such as the properties and content of the drug in the drug layer; however, it can be any amount that allows the drug to be eluted from the drug layer at a desired release rate by swelling. For example, the content of the highly swellable polymer is 50 to 90 mass%, 50 to 85 mass%, 50 to 80 mass%, 55 to 75 mass%, or about 60 to 70 mass%, based on the weight of the push layer.

[0084]

The push layer may also contain other additives. For example, the push layer can contain an osmagent. Examples of

osmagents in the push layer include inorganic salts, inorganic acids, organic salts, organic acids, saccharides, sugar alcohols, and the like. Examples of inorganic salts include sodium chloride, sodium hydrogen carbonate, sodium carbonate, sodium phosphate (trisodium phosphate), potassium phosphate (tripotassium phosphate), sodium hydrogen phosphate (sodium dihydrogen phosphate, disodium hydrogen phosphate), potassium hydrogen phosphate (potassium dihydrogen phosphate, dipotassium hydrogen phosphate), potassium chloride, lithium chloride, magnesium sulfate, magnesium chloride, potassium sulfate, sodium sulfate, sodium hydrogen sulfite, potassium hydrogen sulfite, lithium sulfate, acidic potassium phosphate, and the like. Examples of inorganic acids include acids forming the inorganic salts described above. Examples of organic salts include sodium fumarate (disodium fumarate), sodium hydrogen fumarate (monosodium fumarate), sodium hydrogen tartrate, potassium hydrogen tartrate, sodium tartrate, sodium potassium tartrate, sodium malate (disodium malate), sodium hydrogen succinate, sodium succinate (disodium succinate), sodium hydrogen maleate, sodium maleate (disodium maleate), sodium hydrogen citrate (sodium dihydrogen citrate, disodium hydrogen citrate), sodium citrate (trisodium citrate), and the like. Examples of organic acids include acids forming the organic salts described above. Examples of saccharides and sugar alcohols include mannitol, glucose, lactose, fructose, sucrose, sorbitol, xylitol, erythritol, lactose, and the like. These may be anhydrides or solvates (such as hydrates).

[0085]

Preferable examples of the osmagent contained in the push layer includes sodium chloride, potassium chloride, sodium hydrogen fumarate, sodium fumarate, sodium hydrogen carbonate, sodium carbonate, sodium hydrogen phosphate, sodium phosphate, potassium hydrogen phosphate, potassium phosphate, sodium sulfate, fructose, sucrose, xylitol, sorbitol, glucose, mannitol, erythritol, and lactose. Sodium hydrogen carbonate is particularly preferable. Such osmagents can be used singly, or in a combination of two or more.

[0086]

In the push layer, the osmagent is preferably present in an amount of, for example, 5 to 50 mass%, 15 to 50 mass%, 20 to 50 mass%, 25 to 45 mass%, or about 30 to 40 mass%, based on the weight of the push layer.

[0087]

The push layer may further contain other additives. Examples of such additives include lubricants, fluidizers, pigments, and the like. Preferable examples of lubricants include magnesium stearate. Preferable examples of fluidizers include silicon dioxide (in particular, light anhydrous silicic acid). Preferable examples of pigments include iron oxide.

[0088]

The push layer can contain a lubricant (in particular, magnesium stearate) in an amount of, for example, 0.1 to 5 mass%, based on the weight of the push layer. The push layer can contain a fluidizer (in particular, silicon dioxide) in an amount of, for example, about 0.1 to 5 mass% or 0.1 to 3 mass%, based on the weight of the push layer. Further, the push layer can contain a pigment (in particular, iron oxide) in an amount of, for example, 0.1 to 2 mass%.

[0089]

The semipermeable membrane with which the core formulation is coated includes, for example, a cellulose-based polymer, preferably cellulose acetate, as described above. The semipermeable membrane may also contain a flux-regulating agent. As described above, the flux-regulating agent is preferably, for example, polyethylene glycol (in particular, polyethylene glycol having an average molecular weight of about 2000 to 6000, about 3000 to 5000, or about 3000 to 6000).

[0090]

The semipermeable membrane can contain a cellulose polymer in an amount of, for example, about 70 to 100 mass%, or 75 to 95 mass%, based on the weight of the semipermeable membrane. The semipermeable membrane can contain a flux-regulating agent in an amount of about 0.01 to 30 mass% or about 5 to 25 mass%, based on

the weight of the semipermeable membrane.

[0091]

The coating amount of the semipermeable membrane is preferably an amount that allows high permeability to external fluids, such as water and biological fluids; and that is substantially impermeable to salts of compound (I), highly swellable polymers, and the like. The amount of the semipermeable membrane can be, for example, in an amount of about 5 to 25 parts by mass per 100 parts by mass of the core formulation. The upper limit or the lower limit of this range is, for example, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, or 24 parts by mass. The range can be, for example, about 5 to 25 parts by mass.

[0092]

A water-soluble polymer coating may be applied between the core formulation and the semipermeable membrane in the oral solid pharmaceutical formulation of an osmotic pump controlled release system. In other words, the formulation may have a structure in which a water-soluble polymer membrane and a semipermeable membrane are laminated (preferably applied for coating) in this order on the core formulation.

[0093]

The water-soluble polymer membrane may contain, as a water-soluble polymer, those described above as hydrophilic polymers that can be contained in the drug layer. Among such polymers, for example, hydroxypropylmethyl cellulose, polyvinyl alcohol, a polyvinyl alcohol-polyethylene glycol graft copolymer, and polyvinylpyrrolidone are preferable. Such water-soluble polymers can be used singly, or in a combination of two or more. When the water-soluble polymer membrane contains hydroxypropylmethylcellulose, for example, 60 to 100 mass% of the water-soluble polymer film may be hydroxypropylmethylcellulose. When the water-soluble polymer membrane contains polyvinylpyrrolidone, for example, 0 to 40 mass% of the water-soluble polymer film may be polyvinylpyrrolidone.

[0094]

The water-soluble polymer membrane can be present, for

example, in an amount of about 1 to 15 parts by mass, per 100 parts by mass of the core formulation.

[0095]

The oral solid pharmaceutical formulation of the present disclosure can be used, for example, as bare tablets containing the above-mentioned components and having no color coating layer. For example, from the viewpoint of imparting distinctiveness to the formulation, or long-term storage stability and preventing degradation by light, it is preferable to make tablets coated with a color coating layer. If necessary, the coating layer may additionally contain pharmaceutical additives that are usually used in coating treatment (film formation) of pharmaceutical products for oral administration, such as a coating agent, a plasticizer, a dispersant, and an antifoaming agent. If a color coating layer is provided, the color coating layer is preferably the outermost layer. A known coating agent can be used for the color coating layer. For example, a representative premix additive, such as Opadry, can be used as the coating agent. Preferable examples include coating agents comprising hydroxypropyl methylcellulose, polyvinyl alcohol, a polyvinyl alcohol-polyethylene glycol graft copolymer, a polyvinyl alcohol-acrylic acid-methyl methacrylate copolymer, or the like as a base material; and further comprising a coloring agent, a lubricant, a plasticizer, or the like.

[0096]

A preferred example of the oral solid pharmaceutical formulation of an osmotic pump controlled release system according to the present disclosure is a formulation comprising a core formulation comprising a drug layer and a push layer,

wherein

the drug layer comprises

5 to 200 mg of a salt of compound (I) in terms of the weight of the free base,

1 to 50 mass% of an additive containing an ion in common with the salt, based on the weight of the drug layer,

5 to 94 mass% of a hydrophilic polymer, based on the weight of the

drug layer,

0.1 to 5 mass% of a lubricant, based on the weight of the drug layer, and

0.1 to 5 mass% of a fluidizer, based on the weight of the drug layer,

the push layer comprises

50 to 90 mass% of a highly swellable polymer, based on the weight of the push layer,

5 to 50 mass% of an osmagent, based on the weight of the push layer,

0.1 to 5 mass% of a lubricant, based on the weight of the push layer, and

0.1 to 2% by weight of a pigment, based on the weight of the push layer,

the core formulation comprises 5 to 25 parts by mass of a semipermeable membrane and 1 to 15 parts by mass of a water-soluble polymer membrane, based on 100 parts by mass of the core formulation,

the semi-permeable membrane comprises 70 to 100 mass% of a cellulose-based polymer and 0.01 to 30 mass% of a water-soluble flux-regulating agent, based on the weight of the semipermeable membrane, and

the core formulation optionally comprising a color coating layer.

[0097]

As described above, another preferable embodiment of the oral pharmaceutical composition according to the present disclosure can be, for example, a hydrogel sustained release composition. More specifically, the hydrogel sustained release composition (hydrogel sustained release formulation) according to the present disclosure contains a salt of compound (I) as an active ingredient, and further contains an additive containing an ion in common with the salt. The hydrogel sustained release composition is preferably, for example, a hydrogel matrix tablet. Hydrogel matrix tablets are a known technique in which the release of a drug is controlled by a hydrogel, which is formed by (in the case of an enteric-coated

tablet, dissolution of the coating film due to a pH increase after gastric excretion, and then) absorption of water in the gastrointestinal tract.

[0098]

As the sustained release base (hydrogel-forming base) in the hydrogel matrix tablet, for example, the hydrophilic polymers mentioned above can be used. Specific examples of usable bases include cellulose-based water-soluble polymers, polyalkylene oxide (e.g., polyethylene oxide), polyalkylene glycol (e.g., polyethylene glycol), polyvinyl alcohol, and the like. As the sustained release base material, the above hydrophilic polymers can be used singly, or in a combination of two or more. It is particularly preferable that the sustained release base material contains at least one cellulose-based water-soluble polymer. When a hydrophilic polymer other than cellulose-based water-soluble polymers (for example, polyethylene oxide) is mainly used as the sustained release base, the hydrophilic polymer is preferably combined with at least one cellulose-based water-soluble polymer.

[0099]

As the cellulose-based water-soluble polymer, for example, a cellulose-based water-soluble polymer known in the field of pharmaceutical science can be preferably used. Preferable examples include cellulose-based water-soluble polymers having a structure in which hydrogen atoms of some of OH groups of the cellulose are replaced with methyl and/or hydroxypropyl groups. Specific examples include hydroxypropyl methylcellulose, hydroxypropyl cellulose, methylcellulose, and the like. The cellulose-based water-soluble polymers can be used singly, or in a combination of two or more.

[0100]

The cellulose-based water-soluble polymer can be any cellulose-based water-soluble polymer. For example, a cellulose water-soluble polymer having a viscosity of 2.5 to 35000 mm^2/s as measured in the form of a 2% aqueous solution can be used. It is particularly preferable to use a cellulose-based water-soluble polymer having a viscosity of 2.5 to 17.5 mm^2/s, as measured in the

form of a 2% aqueous solution.

[0101]

When a cellulose-based water-soluble polymer (e.g., hypromellose) is mainly used as a sustained release base, the cellulose-based water-soluble polymer has a viscosity of 80 to 35000 mm^2/s as measured in the form of a 2% aqueous solution. The phrase "mainly" using the hydrophilic polymer herein means that the amount of the hydrophilic polymer is 50 mass% or more, for example, 80 mass% or more, or 90 mass% or more, based on the total mass of the sustained release base.

[0102]

The core tablet can contain the sustained release base in an amount of, for example, about 30 to 90 mass%, or about 50 to 80 mass%, based on the weight of the core tablet.

[0103]

As the additive containing an ion in common with the salt of compound (I) in the hydrogel matrix tablet, the additives described above can be appropriately used. The hydrogel matrix tablet can contain the additive in an amount of, for example, about 1 to 50 mass%, or about 10 to 30 mass%, based on the mass of the core tablet.

[0104]

The hydrogel matrix tablet can further contain other additives. Examples of such additives include lubricants, fluidizers, and the like. Examples of preferable lubricants include magnesium stearate and the like. The hydrogel matrix tablet can contain a lubricant in an amount of, for example, 0.1 to 5 mass%, or 0.2 to 3 mass%, based on the weight of the core tablet. Examples of preferable fluidizers include silicon dioxide (in particular, light anhydrous silicic acid). The hydrogel matrix tablet can contain a fluidizer in an amount of, for example, about 0.1 to 5 mass%, or about 0.1 to 3 mass%, based on the mass of the core tablet.

[0105]

The hydrogel matrix tablet more preferably comprises an enteric coating. A known enteric coating composition can be used for

enteric coating. For example, an enteric coating composition containing an enteric base such as Eudragit, a plasticizer such as triethyl citrate, and a lubricant such as talc, can be preferably used. The hydrogel matrix tablet preferably contains an enteric coating in an amount of, for example, about 1 to 40 parts by mass, or 10 to 30 parts by mass, per 100 parts by mass of the core tablet.

[0106]

A preferred example of the hydrogel sustained release formulation according to the present disclosure is a formulation containing 5 to 200 mg of a salt of compound (I) in terms of the weight of the free base of compound (I); further containing 1 to 50 mass% of an additive containing an ion in common with a salt of compound (I) based on the mass of the core tablet, 30 to 90 mass% of a sustained release base material based on the mass of the core tablet, and 0.1 to 5 mass% of a lubricant based on the weight of the core tablet; and further comprising an enteric coating in an amount of 1 to 40 parts by mass based on 100 parts by mass of the core formulation.

[0107]

In this specification, the term "comprising" includes "consisting essentially of" and "consisting of." Further, the present disclosure includes any and all combinations of the components described herein.

[0108]

Various characteristics (properties, structures, functions, etc.) described in the above embodiments of the present disclosure may be combined in any manner to specify the subject matter included in the present disclosure. That is, this disclosure includes all of the subject matter comprising any combination of the combinable properties described herein.

Examples

[0109]

The present invention is described below more specifically with reference to Examples, Test Examples, etc. However, the present

disclosure is not limited to these Examples. The compound (I) means 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

[0110]

Preparation of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one fumarate

A suspension of 4.22 kg of fumaric acid in 32.5L of water and 22.16 kg of ethanol was stirred under reflux to dissolve fumaric acid (reflux temperature: about 82°C). The obtained solution was filtered while washing with 11.86 kg of ethanol to obtain a fumaric acid solution. A suspension of 15.0 kg of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one in 25.96 kg of water, 8.32 kg of acetic acid, and 34.0 L of ethanol was stirred under reflux to dissolve 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (reflux temperature: about 83°C). The obtained solution was added to the fumaric acid solution, and then filtered while washing with 11.86 kg of ethanol. The filtrate was stirred under reflux for 15 minutes (reflux temperature: about 82°C), then cooled to 30°C or lower, and separated into a solid and a liquid. The obtained solid was washed with water, dried at 80°C, and then moistened to obtain 16.86 kg of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one fumarate.

[0111]

Infrared Absorption Spectrum

The IR spectrum of the fumaric acid salt prepared by the above method was measured by the KBr tablet method using a Fourier transform infrared spectrophotometer (IRPrestige-21) manufactured by Shimadzu Corporation. As shown in Fig. 11a, the IR spectrum showed absorption at wavenumbers of 3657 cm^{-1}, 1711 cm^{-1}, 1643 cm^{-1}, 1416 cm^{-1}, 1227 cm^{-1}, and 839 cm^{-1}.

[0112]

Powder X-Ray Diffraction

The powder X-ray diffraction of the fumaric acid salt prepared by the above method was measured using an X-ray diffractometer (D8 ADVANCE) manufactured by Bruker AXS. Fig. 11b

shows the powder X-ray diffraction pattern of the fumaric acid salt. As shown in Fig. 11b, diffraction peaks were observed at 2θ = 7.6°, 15.1°, 17.7°, 18.9°, and 19.2°. Other peaks were observed at 2θ = 9.8°, 11.3°, 12.2°, 14.0°, 16.5°, 17.0°, 21.2°, 22.3°, 22.7°, 23.8°, 24.2°, 24.7°, 25.4°, 26.5°, 26.9°, 27.9°, 28.9°, 31.9°, 32.3°, 32.6°, and 34.2°.

[0113]

Measurement of Water Content

The water content of the prepared fumaric acid salt was measured. Specifically, the water content was measured by the Karl Fischer method (coulometric titration method) using a water content measuring device (Titrando 852) manufactured by Metrohm. The results confirmed that the water content of the fumaric acid salt was 3.01 wt.%.

[0114]

Preparation of Drug Sustained Release Formulation and Evaluation 1

An osmotic pump controlled release composition (formulation) comprising a bilayered compressed core comprising a drug layer for providing sustained release of a salt of compound (I) and a push layer was produced according to a known general production process. More specifically, a drug layer composition containing a salt of compound (I) and other inert agents, and a push layer composition containing an osmotic agent and a highly viscous polymer were separately produced; and each composition was then compressed into a bilayered tablet core using a known core compression technique.

[0115]

Subsequently, the bilayered compressed core was coated with a composition comprising a water-soluble polymer. As a composition of a water-soluble polymer, hypromellose (hydroxypropyl methylcellulose; TC-5, produced by Shin-Etsu Chemical Co., Ltd.) and povidone (polyvinylpyrrolidone; Kollidon K30, BASF) (70:30 (W/W%)) were dissolved in water to 8% in terms of solids content to prepare a coating solution. This water-soluble polymer coating solution was coated on the bilayered compressed core as prepared above using a

pan coater until the coating component accounted for 10% of the mass of the bilayered compressed core.

[0116]

Further, the obtained water-soluble coating bilayered compressed core was coated with a semipermeable membrane composition. As the semipermeable membrane composition, cellulose acetate and polyethylene glycol 4000 (85:15 (W/W%)) were dissolved to 5% in terms of solids content in acetone/water (95:5 (W/W%)) as a solvent, thus obtaining a coating solution. This coating solution was applied to the water-soluble coating bilayered compressed core produced above using a pan coater until the coating component accounted for 10% of the mass of the bilayered compressed core. The coated core was removed from the pan coater, and then subjected to drying treatment at 40°C for 24 hours using a rack dryer.

[0117]

The thus-coated bilayered compressed core was provided with drug release ports having a diameter of 0.8 mm on the drug-layer-side surface using an automated laser to prepare an osmotic pump formulation.

[0118]

Table 1 below shows the components of the osmotic pump formulation.

[0119]

Table 1

	Formulation (mg/unit)	Example 1-1	Example 1-2	Example 1-3	Example 1-4	Example 1-5
	Core tablet components					
Drug layer	Fumaric acid salt of compound (I)	39.27	39.27	39.27	39.27	39.27
	Low-viscosity polyethylene oxide	89.73	89.73	89.73	89.73	89.73

	Iron oxide	0.20	0.20	0.20	0.20	0.20
	Magnesium stearate	0.40	0.40	0.40	0.40	0.40
	Subtotal	230.00	230.00	230.00	230.00	230.00
	Coating components					
Water-soluble polymer	HPMC TC-5R	16.10	16.10	16.10	16.10	16.10
	Kollidon K30	6.90	6.90	6.90	6.90	6.90
Semi-permeable membrane components	Cellulose acetate	19.55	19.55	19.55	19.55	19.55
	PEG 4000	3.45	3.45	3.45	3.45	3.45
	Subtotal	46.00	46.00	46.00	46.00	46.00
	Total	276.00	276.00	276.00	276.00	276.00

The formulations obtained in the Examples were subjected to the following Test Example 1 and Test Example 2, and evaluated.

[0120]

As the low-viscosity polyethylene oxide, POLYOX (trademark) WSR N-80 (average molecular weight: about 200000, viscosity: 55 to 90 mPa·s (5% W/V aqueous solution, 25°C)) was used. As the high-density polyethylene oxide, POLYOX (registered trademark) WSR Coagulant (average molecular weight: 5000000, viscosity: 5500 to 7500 mPa·s (1% W/V aqueous solution, 25°C)) was used.

[0121]

Test Example 1

The release rate from the formulations obtained in the Examples was evaluated by measuring the dissolution rate of each salt of compound (I) at intervals of 30 minutes to 2 hours over 24 hours. The dissolution test was performed according to the 15th Japanese Pharmacopoeia Dissolution Test Method 2 (paddle method). As a test liquid, 900 mL of a 0.05 mol/L acetate buffer solution (pH

about 4.3, acetic acid, sodium acetate) was used, and the test was performed at 37°C and a paddle rotation speed of 50 rpm. Sampling was performed over time, and the amount of compound (I) (free base) in the sampling solution was quantified with a UV detector (absorbance measurement wavelength: 323 nm and 380 nm). The dissolution mass ratio (%) of compound (I) (free base) relative to the total amount (mass) of compound (I) (free base) in the formulation taken as 100% was defined as the dissolution rate. Since the dissolution rate value is the same as the mass ratio (%) of the dissolved salt of compound (I) relative to the total amount (mass) of the salt of compound (I) in the formulation taken as 100%, the dissolution rate value can also be used as the dissolution rate of the salt of compound (I). Fig. 1a shows the results. The term "Dissolved (%)" in Fig. 1 indicates the dissolution rate.

[0122]

Test Example 2

The release rate from the formulation of each Example was evaluated by measuring the dissolution rate of a salt of compound (I) at 1-hour intervals over 24 hours. The dissolution test was performed according to the 15th Japanese Pharmacopoeia Dissolution Test Method 2 (paddle method). As a test liquid, 900 mL of the second dissolution test liquid (pH of about 7, potassium dihydrogen phosphate, disodium hydrogen phosphate) listed in the Japanese Pharmacopoeia was used, and the test was performed at 37°C and a paddle rotation speed of 50 the rpm. Sampling was performed over time, and the compound (I) (free base) in the sampling solution was quantified with a UV detector (absorbance measurement wavelength: 323 nm and 380 nm). The first wavelength (323 nm) was set as the wavelength at which the absorbance of the main drug can be detected to the maximum, and the second wavelength (380 nm) was set as the wavelength at which the absorbance from the main drug is not detected. Fig. 1b shows the results. In the figure, dissolved (μg/mL) indicates the concentration of the eluted (dissolved) compound (I) (free base).

[0123]

In Test Example 1, the eluate had a pH of about 4.3. The evaluation results of the dissolution test in Test Example is an indicator as to what degree the salt of compound (I) will dissolve in the entire gastrointestinal tract after the oral administration of the oral pharmaceutical composition. The sustained release time of the oral pharmaceutical composition can be evaluated from the obtained profile.

[0124]

On the other hand, in Test Example 2, the pH of the eluate was about 7. The evaluation results of the dissolution test in Test Example 2 show to what level the salt of compound (I) is eluted in the lower part of the gastrointestinal tract after the oral pharmaceutical composition is orally administered and passed through the stomach. In Test Example 2, the following phenomenon was observed: since the solubility of the salt of the compound (I) is higher than the solubility of compound (I), the dissolution concentration of the salt of compound (I) from the formulation temporarily exceeds the solubility of compound (I) to show a supersaturated concentration, after which the dissolution concentration decreases with recrystallization of compound (I). The profile obtained at that time is defined as a supersaturated dissolution profile, and can be evaluated as an indicator of absorbability in the lower part of the gastrointestinal tract.

[0125]

The above results confirmed that formulations particularly containing fumaric acid or monosodium fumarate as an osmagent in the drug layer exhibit excellent supersaturated dissolution profiles (Fig. 1(b)), and were particularly preferable.

[0126]

Preparation of Drug Sustained Release Formulation and Evaluation 2

The oral pharmaceutical compositions (osmotic pump formulations) shown in Table 2 were prepared in the same manner as the method disclosed above in section "Preparation of Drug Sustained Release Formulation and Evaluation 1," except that the kinds and

amounts of core tablet components and coating components were changed as shown in Table 2. The formulations obtained in the Examples shown in Table 2 were evaluated in the same manner as above in Test Example 2. Table 2 shows the results.

[0127]

Table 2

	Formulation (mg/unit)	Example 2-1	Example 2-2	Example 2-3	Example 2-4
	Core tablet components				
Drug layer	Fumaric acid salt of compound (I)	39.27	39.27	39.27	39.27
	Low-viscosity polyethylene oxide	89.73	69.73	69.73	69.73
	Monosodium fumarate	30.00	30.00	30.00	30.00
	Hypromellose TC-5R	-	20.00	-	-
	Low-substituted hydroxypropyl cellulose	-	-	20.00	-
	Polyethylene glycol 6000	-	-	-	20.00
	Magnesium stearate	1.00	1.00	1.00	1.00
Push layer	High-viscosity polyethylene oxide	45.40	45.40	45.40	45.40
	Sodium hydrogen carbonate	24.00	24.00	24.00	24.00
	Iron oxide	0.20	0.20	0.20	0.20
	Magnesium stearate	0.40	0.40	0.40	0.40
	Subtotal	230.00	230.00	230.00	230.00
	Coating components				
Water-soluble polymer	HPMC TC-5R	16.10	16.10	16.10	16.10
	Kollidon K30	6.90	6.90	6.90	6.90
Semi-permeable membrane components	Cellulose acetate	31.05	31.05	31.05	31.05
	PEG 4000	3.45	3.45	3.45	3.45
	Subtotal	57.50	57.50	57.50	57.50
	Total	287.50	287.50	287.50	287.50

The above results confirmed that formulations particularly containing hypromellose (hydroxypropyl methylcellulose) as a carrier (particularly a hydrophilic polymer) have an excellent supersaturated dissolution concentration profile, and were found to be more preferable.

[0128]

Preparation of Drug Sustained Release Formulation and Evaluation 3

The oral pharmaceutical compositions (osmotic pump formulations) shown in Table 3 were prepared in the same manner as the method disclosed above in section "Preparation of Drug Sustained Release Formulation and Evaluation 1," except that the kinds and amounts of core tablet components and coating components were changed as shown in Table 3. The formulations obtained in the Examples shown in Table 3 were evaluated in the same manner as above in Test Example 1. Fig. 3 shows the results.

The above results confirmed that the formulations obtained in all the Examples exhibit excellent sustained release properties (Fig. 3). Further, it was found that when sodium hydrogen carbonate or sodium chloride is used as an osmagent in the push layer, the slope of the dissolution rate graph in Fig. 3 is more constant (that is, the dissolution of the salt of compound (I) continues at a constant rate), and is preferable from this viewpoint. It was also found that when sodium chloride was used, the obtained final dissolution rate was slightly lower than that achieved when other osmagents were used. From the above results, the use of sodium hydrogen carbonate was found to be particularly preferable because a high final dissolution rate is obtained, and the dissolution continues at a constant rate.

[0130]

Preparation of Drug Sustained Release Formulation and Evaluation 4

The oral pharmaceutical compositions (osmotic pump formulations) shown in Table 4 were prepared in the same manner as the method disclosed above in section "Preparation of Drug Sustained Release Formulation and Evaluation 1," except that the kinds and amounts of core tablet components and coating components were changed as shown in Table 4. The formulations obtained in the Examples shown in Table 4 were evaluated in the same manner as above in Test Examples 1 and 2. However, in Test Example 1 of the evaluation, a liquid prepared by adding a surfactant (cetyltrimethylammonium bromide: CTAB) at a final concentration of 0.5 W/W% to the test liquid used in Test Example 2 was used as the test liquid. This test liquid was constructed so that the surfactant added thereto increases the solubility of compound (I) at a pH of about 7, and allows for 100% dissolution of the drug from the formulation. This test solution was used because it was considered to be more appropriate for evaluating the release of the formulation under pH conditions throughout the gastrointestinal tract.

Figs. 4a and 4b show the results.

[0131]

[0132]

Preparation of Drug Sustained Release Formulation and Evaluation 5

The oral pharmaceutical compositions (osmotic pump formulations) shown in Table 5 were prepared in the same manner as the method disclosed above in section "Preparation of Drug

Sustained Release Formulation and Evaluation 1," except that the kinds and amounts of core tablet components and coating components were changed as shown in Table 5. The formulations obtained in the Examples shown in Table 5 were evaluated in the same manner as above in Test Examples 1 and 2. Figs. 5a and 5b show the results.

[0133]

Table 5

	Formulation (mg/unit)	Example 5-1	Example 5-2	Example 5-3
	Core tablet components			
Drug layer	Fumaric acid salt of compound (I)	39.27	39.27	39.27
	Low-viscosity polyethylene oxide	69.73	69.73	69.73
	Monosodium fumarate	30.00	30.00	30.00
	Hypromellose TC-5R	20.00	20.00	20.00
	Magnesium stearate	1.00	1.00	1.00

	Sodium hydrogen carbonate	24.00	24.00	24.00
	Iron oxide	0.20	0.20	0.20
	Magnesium stearate	0.40	0.40	0.40
	Subtotal	230.00	230.00	230.00
	Coating components			
Water-soluble polymer	HPMC TC-5R	16.10	16.10	16.10
	Kollidon K30	6.90	6.90	6.90
Semipermeable membrane components	Cellulose acetate	20.70	31.05	41.40
	PEG 4000	2.30	3.45	4.60
	Subtotal	46.00	57.50	69.00
	Total	276.00	287.50	299.00

[0134]

These results confirmed that the formulations obtained in all of the Examples showed excellent sustained release properties (Fig. 5(a)). It was also confirmed that the sustained release time can be controlled by changing the amount of the film component (semipermeable component). Even when hypromellose

having a different aqueous solution viscosity was used in the drug layer (more specifically, when TC-5E hypromellose having a viscosity of about 3 mPa·s as measured at 20°C in the form of a 2% aqueous solution was used in place of TC-5R hypromellose having a viscosity of about 6 mPa·s as measured at 20°C in the form of a 2% aqueous solution), the difference in viscosity did not make much difference in the sustained release and supersaturation maintenance effect.

[0135]

Preparation of Drug Sustained Release Formulation and Evaluation 6

The oral pharmaceutical compositions (osmotic pump formulations) shown in Table 6 were prepared in the same manner as the method disclosed above in section "Preparation of Drug Sustained Release Formulation and Evaluation 1," except that the kinds and amounts of core tablet components and coating components were changed as shown in Table 6. The formulations obtained in the Examples shown in Table 6 were evaluated in the same manner as above in Test Examples 1 and 2. However, in Test Example 1 of the evaluation, a liquid prepared by adding a surfactant (cetyltrimethylammonium bromide: CTAB) at a final concentration of 0.5 W/W% to the test liquid used in Test Example 2 was used as the test liquid. Figs. 6a and 6b show the results.

[0136]

Table 6

	Formulation (mg/unit)	Example 6-1	Example 6-2	Example 6-3	Example 6-4
	Core tablet component				
Drug layer	Fumaric acid salt of compound (I)	39.27	39.27	39.27	39.27
	Low-viscosity polyethylene oxide	87.73	67.73	57.73	47.73
	Monosodium fumarate	10.00	30.00	40.00	50.00
	Hypromellose TC-5R	20.00	20.00	20.00	20.00

	Light anhydrous silicic acid Aerosil 200	2.00	2.00	2.00	2.00
	Magnesium stearate	1.00	1.00	1.00	1.00

	Sodium hydrogen carbonate	24.00	24.00	24.00	24.00
	Iron oxide (pigment)	0.20	0.20	0.20	0.20
	Magnesium stearate	0.40	0.40	0.40	0.40
	Subtotal	230.00	230.00	230.00	230.00
	Coating components				
Water-soluble polymer	HPMC TC-5R	16.10	16.10	16.10	16.10
	Kollidon K30	6.90	6.90	6.90	6.90
Semipermeable membrane components	Cellulose acetate	31.05	31.05	31.05	31.05
	PEG 4000	3.45	3.45	3.45	3.45
	Subtotal	57.50	57.50	57.50	57.50
	Total	287.50	287.50	287.50	287.50

[0137]

The above results confirmed that the formulations obtained in all of the Examples showed excellent sustained release properties (Fig. 6(a)). It was also found that when the drug layer contains monosodium fumarate as an osmagent in an amount of about 20 mass% or more, based on the total mass of the drug layer, the optimal sustained release and supersaturation maintenance properties can be obtained.

[0138]

Preparation of Drug Sustained Release Formulation and Evaluation 7

Preparation of Citric Acid Salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one

35 g of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one, 280 mL of ethanol, and 52.5 mL of acetic acid were placed in a *Kolben* flask; and stirred under reflux to dissolve 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (refluxing temperature: about 83°C). After cooling until the reflux subsided, 16.62 g of citric acid

was added to the flask. After washing with 70 mL of ethanol, the mixture was heated with stirring to reflux (reflux temperature: about 82°C). After stirring at reflux, the mixture was cooled to 5°C or less, and separated into a solid and a liquid. The obtained solid was washed with ethanol, and dried at 60°C to obtain 50.32 g of a citric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (unmilled product).

[0139]

Infrared Absorption Spectrum

The IR spectrum of the citric acid salt prepared by the above method was measured by the KBr tablet method using a Fourier transform infrared spectrophotometer (FT-IR IR Affinity-1S) manufactured by Shimadzu Corporation. As shown in Fig. 11c, the IR spectrum showed absorption at wave numbers of around 2959 cm^{-1}, 1713 cm^{-1}, 1626 cm^{-1}, 1416 cm^{-1}, 1227 cm^{-1} and 754 cm^{-1}.

[0140]

Powder X-Ray Diffraction

The X-ray diffraction of the citric acid salt prepared by the above method was measured using an X-ray diffractometer (D8 Advance) manufactured by Bruker AXS. Fig. 11d shows the powder X-ray diffraction pattern of the citric acid salt. As shown in Fig. 11d, diffraction peaks were observed at 2θ = 14.1°, 16.2°, 17.3°, 22.2° and 24.8°. Other diffraction peaks were observed at 2θ = 7.1°, 11.1°, 11.9°, 12.5°, 13.0°, 17.7°, 19.4°, 19.9°, 20.9°, 23.5°, 24.0°, 25.9°, and 28.4°.

[0141]

Measurement of Water Content

The water content of the citric acid salt prepared by the above method was measured. The water content was measured by the Karl Fischer method (coulometric titration method) using a water content measuring device (CA-200) manufactured by Mitsubishi Chemical Analytech. The results confirmed that the water content of the citric acid salt was 0.76 wt.%.

[0142]

Preparation of Tartaric Acid Salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one

35 g of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one, 280 mL of ethanol, and 52.5 mL of acetic acid were placed in a *Kolben* flask; and stirred under reflux to dissolve 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (refluxing temperature: about 83°C). After cooling until the reflux subsided, 12.72 g of L-tartaric acid was added to the flask. After washing with 70 mL of ethanol, the mixture was heated with stirring to reflux (reflux temperature: about 83°C). After stirring at reflux, the mixture was cooled to 5°C or lower, and separated into a solid and a liquid. The obtained solid was washed with ethanol, and dried at 60°C to obtain 46.53 g of a tartaric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (unmilled product).

[0143]

Infrared Absorption Spectrum

The IR spectrum of the tartaric acid salt prepared by the above method was measured by the KBr tablet method using a Fourier transform infrared spectrophotometer (FT-IR IR Affinity-1S) manufactured by Shimadzu Corporation. As shown in Fig. 11e, the IR spectrum showed absorption at wave numbers of 3321 cm^{-1}, 1717 cm^{-1}, 1661 cm^{-1}, 1414 cm^{-1}, 1240 cm^{-1}, and 754 cm^{-1}.

[0144]

Powder X-Ray Diffraction

The powder X-ray diffraction of the tartaric acid salt prepared by the above method was measured using an X-ray diffractometer (D8 Advance) manufactured by Bruker AXS. Fig. 11f shows the powder X-ray diffraction pattern of the tartaric acid salt. As shown in Fig. 11f, diffraction peaks were observed at 2θ = 15.5°, 15.9°, 21.6°, 23.7°, and 24.7°. Other diffraction peaks were observed at 2θ = 10.9°, 11.6°, 12.2°, 13.2°, 16.3°, 16.7°, 17.2°, 18.3°, 18.9°, 19.3°, 20.5°, 22.2°, 25.4°, 26.0°, 26.8°,

27.8°, 32.8°, 34.6°, 35.7°, and 38.7°.

[0145]

Measurement of Water Content

The water content of the tartaric acid salt prepared by the above method was measured. The water content was measured by the Karl Fischer method (coulometric titration method) using a water content measuring device (CA-200) manufactured by Mitsubishi Chemical Analytech. The results confirmed that the water content of the tartaric acid salt was 0.42 wt.%.

[0146]

Preparation of Phosphoric Acid Salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one

35 g of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one, 350 mL of ethanol, and 52.5 mL of acetic acid were placed in a *Kolben* flask; and stirred under reflux to dissolve 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (refluxing temperature: about 82°C). After cooling until the reflux subsided, 5.78 mL of phosphoric acid was added to the flask, and the resulting mixture was heated with stirring to reflux (reflux temperature: about 82°C). After stirring at reflux, the mixture was cooled to 5°C or less, and separated into a solid and a liquid. The obtained solid was washed with ethanol, and dried at 60°C to obtain 41.96 g of a phosphoric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (unmilled product).

[0147]

Infrared Absorption Spectrum

The IR spectrum of the phosphoric acid salt prepared by the above method was measured by the KBr tablet method using a Fourier transform infrared spectrophotometer (FT-IR IR Affinity-1S) manufactured by Shimadzu Corporation. As shown in Fig. 11g, the IR spectrum showed absorption at wave numbers of 2951 cm^{-1}, 1651 cm^{-1}, 1416 cm^{-1}, 1223 cm^{-1}, 1072 cm^{-1}, and 741 cm^{-1}.

[0148]

Powder X-Ray Diffraction

The powder X-ray diffraction of the phosphoric acid salt prepared by the above method was measured using an X-ray diffractometer (D8 Advance) manufactured by Bruker AXS. Fig. 11h shows the powder X-ray diffraction pattern of phosphoric acid salt. As shown in Fig. 11h, diffraction peaks were observed at 2θ = 4.7°, 13.8°, 16.6°, 17.4°, and 22.8°. Other diffraction peaks were observed at 2θ = 11.0°, 11.7°, 12.1°, 14.3°, 15.3°, 18.1°, 19.1°, 19.8°, 21.0°, 21.8°, 22.4°, 23.5°, 24.4°, 24.7°, 25.8°, 27.0°, 27.8°, 28.5°, 30.2°, 30.8°, 33.8°, and 34.2°

[0149]

Measurement of Water Content

The water content of the phosphoric acid salt prepared by the above method was measured. The water content was measured by the Karl Fischer method (coulometric titration method) using a water content measuring device (CA-200) manufactured by Mitsubishi Chemical Analytech. The results confirmed that the water content of the phosphoric acid salt was 0.37 wt.%.

[0150]

Preparation of Hydrochloric Acid Salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one

35 g of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one, 210 mL of ethanol, 70 mL of water, and 52.5 mL of acetic acid were placed in a *Kolben* flask; and stirred under reflux to dissolve 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (refluxing temperature: about 82°C). After cooling until the reflux subsided, 7.27 mL of 36% hydrochloric acid was added to the flask. After washing with 70 mL of ethanol, the resulting mixture was cooled until crystals were precipitated. After crystal precipitation, the resulting mixture was heated with stirring to reflux (reflux temperature: about 81°C). After stirring at reflux, the mixture was cooled to 5°C or lower and stirred at 5°C or lower, and then separated into a solid and a liquid. The obtained solid was washed with ethanol, and air-dried to obtain 36.62 g of a hydrochloric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-

2-one (unmilled product).

[0151]

Infrared Absorption Spectrum

The IR spectrum of the hydrochloric acid salt prepared by the above method was measured by the KCl tablet method using a Fourier transform infrared spectrophotometer (FT-IR IR Affinity-1S) manufactured by Shimadzu Corporation. As shown in Fig. 11i, the IR spectrum showed absorption at wave numbers of 3402 cm^{-1}, 2951 cm^{-1}, 1670 cm^{-1}, 1416 cm^{-1}, 1221 cm^{-1}, and 745 cm^{-1}.

[0152]

Powder X-Ray Diffraction

Powder X-ray diffraction of the hydrochloric acid salt prepared by the above method was measured using an X-ray diffractometer (D8 Advance) manufactured by Bruker AXS. Fig. 11j shows the powder X-ray diffraction pattern of the hydrochloric acid salt. As shown in Fig. 11j, diffraction peaks were observed at 2θ = 16.0°, 20.4°, 20.6°, 23.8° and 24.5°. Other diffraction peaks were observed at 2θ = 5.3°, 6.0°, 7.8°, 9.2°, 10.5°, 12.6°, 13.4°, 14.6°, 15.4°, 17.2°, 17.6°, 17.8°, 18.4°, 19.5°, 21.8°, 25.2°, 25.9°, 26.8°, 27.3°, 28.4°, 29.2°, 29.7°, and 30.7°.

[0153]

Measurement of Water Content

The water content of the hydrochloric acid salt prepared by the above method was measured. The water content was measured by the Karl Fischer method (coulometric titration method) using a water content measuring device (CA-200) manufactured by Mitsubishi Chemical Analytech. The results confirmed that the water content of the phosphoric acid salt was 3.84 wt.%.

[0154]

Preparation of Sulfuric Acid Salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one

35 g of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one, 210 mL of acetonitrile, and 70 mL of water were placed in a *Kolben* flask; and stirred at room

temperature in a suspended state. After adding 4.71 mL of sulfuric acid and 70 mL of acetonitrile to the flask and stirring at room temperature, the resulting mixture was heated to reflux (refluxing temperature: about 78°C). After stirring at reflux, the mixture was cooled to 5°C or less. After stirring at 5°C or less, the mixture was separated into a solid and a liquid. The obtained solid was washed with acetonitrile, and dried at 60°C to obtain 42.45 g of a sulfuric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)-butoxy]-1H-quinolin-2-one (unmilled product).

[0155]

Infrared Absorption Spectrum

The IR spectrum of the sulfuric acid salt prepared by the above method was measured by the KBr tablet method using a Fourier transform infrared spectrophotometer (FT-IR IR Affinity-1S) manufactured by Shimadzu Corporation. As shown in Fig. 11k, the IR spectrum showed absorption at wave numbers of around 2961 cm^{-1}, 1630 cm^{-1}, 1229 cm^{-1}, 1155 cm^{-1}, 1034 cm^{-1}, and 756 cm^{-1}.

[0156]

Powder X-Ray Diffraction

The powder X-ray diffraction of the sulfuric acid salt prepared by the above method was measured using an X-ray diffractometer (D8 Advance) manufactured by Bruker AXS. Fig. 11l shows the powder X-ray diffraction pattern of sulfuric acid salt. As shown in Fig. 11l, diffraction peaks were observed at 2θ = 12.1°, 17.6°, 20.5°, 22.8°, and 24.1°. Other diffraction peaks were observed at 2θ = 4.3°, 11.5°, 12.7°, 12.9°, 13.5°, 14.1°, 14.6°, 15.4°, 15.6°, 17.2°, 18.7°, 19.1°, 19.7°, 22.3°, 25.0°, 26.8°, 27.2°, 28.6°, 29.3°, 29.9°, 32.8°, 34.1°, 34.8°, and 37.8°.

[0157]

Measurement of Water Content

The water content of the sulfuric acid salt prepared by the above method was measured. The water content was measured by the Karl Fischer method (coulometric titration method) using a

water content measuring device (CA-200) manufactured by Mitsubishi Chemical Analytech. The results confirmed that the water content of the phosphoric acid salt was 0.41 wt.%.

[0158]

Osmotic pump formulations were prepared by basically using the same composition as the osmotic pump formulation of Example 6-3, except that the drug layer was formed using a different salt of compound (I) in place of the fumaric acid salt of compound (I), and using a different component in place of the monosodium fumarate.

[0159]

More specifically, osmotic pump formulations were prepared in the same manner as above by using the same kinds and amounts of components as in Example 6-3; however, to form the drug layer, the components shown in Table 7a were used in the amounts shown in Table 7a as a carrier (in place of the hypromellose (HPMC) TC-5R used in Example 6-3), and the components shown in Table 7a were used in the amounts shown in Table 7a as water-soluble polymers (in place of the HPMC TC-5R and Kollidon K30 used in Example 6-3). In Table 7a, Metolose SM-4 is methyl cellulose, HPC-SL is hydroxypropyl cellulose, and Kollicoat IR is a polyvinyl alcohol-polyethylene glycol-graft copolymer.

[0160]

Further, osmotic pump formulations were prepared in the same manner as above by using the same kinds and amounts of components as in Example 6-3; however, to form the drug layer, various kinds of salts shown in Table 7b were used in the amounts shown in Table 7b as salts of compound (I) (in place of the fumaric acid used in Example 6-3), various components shown in Table 7b were used in the amounts shown in Table 7b as osmagents (in place of the monosodium fumarate used in Example 6-3), and the amount of the low-viscosity polyethylene oxide used was changed to the amount shown in Table 7a; and no carriers (instead of using the hypromellose (HPMC) TC-5R in Example 6-3) were used.

Furthermore, to form the coating layer, the components shown in Table 7b were used in the amounts shown in Table 7b as water-soluble polymers of the coating component (in place of the HPMC TC-5R and Kollidon K30 used in Example 6-3), and the amounts of the semipermeable membrane components of the coating component were changed to 19.55 mg/unit of cellulose acetate and 3.45 mg/unit of PEG 4000. In Table 7b, Kollicoat IR is a polyvinyl alcohol-polyethylene glycol-graft copolymer.

CA 03150827 2022-02-11

Date Reçue/Date Received 2022-02-11

The release rates of the osmotic pump formulations obtained in the Case Examples were evaluated in the same manner as in Test Example 1 and Test Example 2 above. Figs. 7 and 8g show the results of evaluating the release rate in the same manner as in Test Example 1. Figs. 8a to 8f show the results of evaluating the release rate in the same manner as in Test Example 2.

[0163]

Preparation of Drug Sustained Release Formulation and Evaluation 8

Hydrogel sustained release formulations (hydrogel matrix tablets) were produced according to the compositions shown in Table 8 by a usual known production process. More specifically, the components were mixed and compressed into tablets using a known core compression technique to prepare a hydrogel matrix tablet (uncoated tablet). Hydrogel matrix tablets are a known technique in which the release of a drug is controlled by a hydrogel, which is formed by (in the case of an enteric-coated tablet, dissolution of the coating film due to a pH increase after gastric excretion, and then) absorption of water in the gastrointestinal tract. In the compositions shown in Table 8, hypromellose was used as a sustained release base (hydrogel-forming base).

[0164]

Table 8

Pharmaceutical composition (mg/unit)	Case Example 8A-1	Case Example 8A-2
Fumaric acid salt of compound (I)	39.27	39.27
Hypromellose 90SH-4000SR	89.73	119.73
Sodium hydrogen fumarate	30.00	-
Magnesium stearate	1.00	1.00
Total	160.00	160.00

Further, an enteric coating can be preferably applied

to the uncoated tablets. A known enteric coating composition can be used for the enteric coating. For example, an enteric coating composition containing Eudragit can be preferably used.

[0165]

The obtained hydrogel matrix tablets (uncoated tablets) were evaluated for the release rate in the same manner as in Test Example 1 and Test Example 2 above. Hydrogel matrix tablets prepared without using the fumaric acid salt of compound (I) were also evaluated in the same manner. Fig. 9a shows the results of evaluating the release rate in the same manner as in Test Example 1. Fig. 9b shows the results of evaluating the release rate in the same manner as in Test Example 2.

[0166]

Hydrogel matrix tablets (uncoated tablets) were prepared in the same manner as above using the same compositions as shown in Table 8, except that hypromellose TC-5R and polyethylene oxide (MW:7000K) were used in place of hypromellose as the sustained release base (Table 9). The obtained hydrogel matrix tablets were evaluated for the release rate in the same manner as in Test Example 1 and Test Example 2 above. Further, the hydrogel matrix tablets prepared without using sodium hydrogen fumarate and those prepared without using hypromellose were evaluated in the same manner. Fig. 10a shows the results of evaluating the release rate in the same manner as in Test Example 1. Fig. 10b shows the results of evaluating the release rate in the same manner as in Test Example 2.

[0167]

[0168]

Formulation Examples of Osmotic Pump Formulations

Table 10 shows Formulation Examples of osmotic pump formulations comprising the oral pharmaceutical compositions according to the present disclosure. In Table 10, the amounts of components of the drug layer and the push layer are expressed in parts by mass, whereas the amounts of components of the coating layer are expressed in parts by mass based on 100 parts by mass of the core portion. The "core portion" referred to herein means the part of a combination of the drug layer and the push layer.

Evaluation of Blood Concentration of Compound (I) After Oral Administration to Humans

The blood concentration of compound (I) in a steady state after oral administration of the oral pharmaceutical composition according to the present disclosure to a human is evaluated based on the following single-dose administration protocol and multiple-dose administration protocol. The formulation (test formulation) used in this evaluation is an osmotic pump formulation prepared according to the present disclosure, which contains a fumaric acid salt of compound (I) as an active ingredient. The doses and contents of the tablets shown in the table below are in terms of the free base, i.e., the weight of compound (I). In the single-dose administration protocol, 24 mg of the test formulation (one 24 mg tablet) is administered once on an empty stomach. Then, after a washout period, 48 mg of the test formulation (two 24 mg tablets) is administered once on an empty stomach. In the multiple-dose administration protocol, the test formulation is repeatedly administrated on an empty stomach by any one of the following administration methods 1 to 5. In each protocol, the PK parameter of compound (I) is analyzed. The observation shows that the formulation maintains a desirable steady-state blood concentration of compound (I) as a drug for a once-a-week administration (for example, 15 ng/mL to 400 ng/mL).

[0171]

Table 11

Date of administration	First day			8th day, 15th day, 22th day, and 29th day		
Administration method	Dose	Tablet	Number of tablets	Dose	Tablet	Number of tablets
1	24 mg	24 mg	1 tablet	48 mg	24 mg	2 tablets
2	18 mg	18 mg	1 tablet	36 mg	18 mg	2 tablets
3	24 mg	24 mg	1 tablet	42 mg	18 mg 24 mg	1 tablet each
4	30 mg	30 mg	1 tablet	54 mg	24 mg 30 mg	1 tablet each
5	30 mg	30 mg	1 tablet	60 mg	30 mg	2 tablets

CLAIMS

[Claim 1]

A controlled release oral solid pharmaceutical composition comprising a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one as an active ingredient, and further comprising an additive containing an ion in common with the salt.

[Claim 2]

The composition according to claim 1, wherein the active ingredient is a fumaric acid salt, a phosphoric acid salt, a hydrochloric acid salt, a sulfuric acid salt, a citric acid salt, or a tartaric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

[Claim 3]

The composition according to claim 1, wherein the active ingredient is a fumaric acid salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one, and the additive containing an ion in common with the salt is at least one member selected from the group consisting of fumaric acid, monosodium fumarate, and disodium fumarate.

[Claim 4]

The composition according to any one of claims 1 to 3, further comprising a cellulose-based water-soluble polymer.

[Claim 5]

The composition according to claim 4, wherein the cellulose-based water-soluble polymer is at least one member selected from the group consisting of hydroxypropyl methylcellulose, hydroxypropyl cellulose, and methyl cellulose.

[Claim 6]

The composition according to any one of claims 1 to 5, which is an osmotic pump composition.

[Claim 7]

The composition according to claim 6, wherein the osmotic pump composition comprises a drug layer comprising a cellulose-based water-soluble polymer.

[Claim 8]

The composition according to claim 7, wherein the cellulose-based water-soluble polymer is hydroxypropyl methyl cellulose.

[Claim 9]

The composition according to any one of claims 1 to 5, which is a hydrogel sustained release formulation.

[Claim 10]

The composition according to claim 9 comprising an enteric coating.

[Claim 11]

The composition according to any one of claims 1 to 10, which contains 5 mg to 60 mg of the active ingredient in terms of the weight of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one.

[Claim 12]

The composition according to any one of claims 1 to 11, wherein the blood concentration of 7-[4-(4-benzo[b]thiophen-4-ylpiperazin-1-yl)butoxy]-1H-quinolin-2-one in a steady state when orally administered to a human is maintained in the range of 15 ng/mL to 400 ng/mL for 1 week.

[Claim 13]

The composition according to any one of claims 1 to 12, which is for use in administering a salt of 7-[4-(4-benzo[b]thiophen-4-yl-piperazin-1-yl)butoxy]-1H-quinolin-2-one once a week at a dose of 5 mg to 60 mg in terms of the weight of the free base.

[Claim 14]

The composition according to any one of claims 1 to 13, which is for use in preventing or treating a central nervous system (CNS) disease.

[Claim 15]

The composition according to claim 14, wherein the composition is for preventing or treating a CNS disease selected from the group consisting of schizophrenia; treatment-resistant, refractory, or chronic schizophrenia; emotional disturbance; psychotic disorder; mood disorder; bipolar disorder; depression, endogenous depression; major depression; melancholic and treatment-resistant depression; dysthymic disorder; cyclothymic disorder; anxiety disorder; somatoform disorder; factitious disorder; dissociative disorder; sexual disorder; eating disorder; sleep disorder; adjustment disorder; substance-related disorder; anhedonia; delirium; cognitive impairment; cognitive impairment associated with neurodegenerative disease; cognitive impairment caused by neurodegenerative disease; cognitive impairment of schizophrenia; cognitive impairment caused by treatment-resistant, refractory, or chronic schizophrenia; vomiting; motion sickness; obesity; migraine; pain; mental retardation; autism disorder; Tourette's disorder; tic disorder; attention deficit hyperactivity disorder; conduct disorder; Down syndrome; impulsive symptoms associated with dementia; and borderline personality disorder.
