(57) Abrégé/Abstract:
A method for differentiated access control on a computing device, and the computing device, the method including starting a timer on the computing device; resetting the timer if activity occurs on the computing device prior to the expiration of the timer; and preventing a subset of applications from being launched or enabled on expiry of the timer.
ABSTRACT

A method for differentiated access control on a computing device, and the computing device, the method including starting a timer on the computing device; resetting the timer if activity occurs on the computing device prior to the expiration of the timer; and preventing a subset of applications from being launched or enabled on expiry of the timer.
METHOD AND APPARATUS FOR DIFFERENTIATED ACCESS CONTROL

[0001] FIELD OF THE DISCLOSURE
[0002] The present disclosure relates to computing devices and in particular relates to application security on the computing devices.

BACKGROUND
[0003] Computing devices, including mobile devices such as personal digital assistants, smart phones, cellular telephones, laptops, among others, as well as desktop or other computing devices have the capability of running multiple applications at one time. For security purposes, a user or an IT policy for the user may dictate that the computer device lock access to the applications that are running after a period of inactivity. For example, if the user has not touched the computing device for 2 minutes, all of the applications on the device may lock. The user is then required to enter a password prior to the use of any application on the device.

BRIEF DESCRIPTION OF THE DRAWINGS
[0004] The present application will be better understood with reference to the drawings, in which:

Figure 1 is an example representation of a user interface showing a cover flow style with running applications;

Figure 2 is a representation of an example user interface in which the mobile device is locked and requires a password;

Figure 3A is an example user interface representation showing a cover sheet with running applications in which a subset has been locked;

Figure 3B is another example user interface representation showing a cover flow with running applications in which a subset has been locked;
**Figure 3B** is another example user interface representation showing a cover flow with running applications in which a subset has been locked;

**Figure 4** shows a data flow diagram for locking a subset of applications;

**Figure 5** shows an example diagram of a table which has a plurality of locked times for various application subsets;

**Figure 6** is a data flow diagram showing the locking of various subsets of applications at different times;

**Figure 7** is a flow diagram showing the launching or enabling of an application;

**Figure 8** shows a simplified block diagram of a computing device; and

**Figure 9** is a block diagram of an example mobile device capable of being used with the present disclosure.

**DETAILED DESCRIPTION**

[0005] The present disclosure provides a method for providing differentiated access control on a computing device, the method comprising: starting a timer on the computing device, the timer being an inactivity timer for at least one of a plurality of application subsets; resetting the timer if activity occurs on the computing device prior to the expiration of the timer; and preventing each application associated with the at least one of the plurality of application subsets from being launched or enabled on expiry of the timer.

[0006] The present disclosure further provides a computing device comprising: a processor; a user interface; and memory, wherein the processor, user interface and memory cooperate to: start a timer on the computing device, the timer being an inactivity timer for at least one of a plurality of application subsets; reset the timer if activity occurs on the computing device prior to the expiration of the timer; and prevent each application associated with the at least one of the plurality of application subsets from being launched or enabled on expiry of the timer.

[0007] When a user is interacting with a computing device, he or she may have multiple applications running at one time. Some of these applications
may be work oriented and some may be personal oriented. For example, work oriented applications may include, but are not limited to, customer relationship management software, enterprise resource planning software, server or desktop virtualization software such as Citrix™, among others. Examples of personal applications may include, but are not limited to, various social networking applications, games, really simple syndication (RSS) readers among others. Hybrid applications which may involve both personal and business oriented functionality, such as email applications may, for security reasons, be considered to be corporate applications.

[0008] When used herein, a computing device can be any device capable of running applications and providing a user interface to a user. Examples of computing devices include desktop computers, personal computers, tablets, mobile devices such as smartphones, personal digital assistants (PDAs), digital data devices, among others. The present disclosure is not meant to be limited to any particular computing device.

[0009] Many computing devices include an inactivity lock out period. After the inactivity period expires, the device locks and the user must enter a password prior to being permitted to continue utilizing applications that are already running or launching new applications.

[0010] One issue is that when a device locks, access to both personal and work oriented applications will also lock. This may be due to an IT policy which required that work items be locked after a certain inactivity time. However, it may not be ideal to force a strict policy onto a user's personal applications merely because work applications are being protected.

[0011] The present disclosure provides for a navigation entity that manages launching applications. The entity is aware of which applications are work (business) oriented and which are personal oriented. In case of locking the device from inactivity, the navigation entity can ensure that only work oriented
applications require an authentication mechanism such as a password entry to regain access to them.

[0012] In other embodiments, applications can be further differentiated into different classes of applications, and various classes of applications can have different inactivity times. Upon the expiration of the inactivity time for a particular class of applications, that class of applications can then be locked and require a password to launch or enable applications already running which are of that class. Any number of classes can be used, and at one extreme each application on the device can have its own class.

[0013] Defining the class of an application, for example personal or corporate, can be done by various entities, and the present disclosure is not meant to be limited to any particular entity defining the class of the application. In one embodiment, an enterprise information technology (IT) department may deem various applications to be work oriented and thus can, on an enterprise server or on the individual devices, designate that certain applications are considered to fall with a particular class. For example, with the two-class system of work and personal applications, the IT department can designate which applications are considered to be work applications on a user's device. The remaining applications on the device can then, by default, be designated as personal applications.

[0014] In other embodiments, the user can set the IT policy himself or herself for security purposes. Thus, the navigator entity can have a configuration option in which the various applications are configured to be either work or personal applications in a two-class system or can be configured to be one of various classes in a multi-class system. This permits the user to have a level of security if, for example, they leave their computer running or if a laptop or mobile device that they carry is misplaced or stolen.

[0015] A user utilizing the differentiated access system as described above can have easy access to their personal data and applications while at the
same time providing for a secure environment for corporate or corporate applications meeting the IT policies of their enterprise.

[0016] Reference is now made to Figure 1. Figure 1 shows an example user interface. In one potential embodiment, the user interface may comprise a grid style type interface that shows thumbnails of applications that are currently running or potential applications that may be launched. Thus, for example, in Figure 1, user interface 110 on mobile device 100 includes icons 120, 122, 124, 126, 128 and 130. Each of these thumbnails can represent an application that is currently running, for example. In one embodiment, the grid style may show the current screen shot of the application as it is currently running. Thus, for example, icon 128 may represent a spreadsheet application or spreadsheet viewer that shows a view of the data on a current spreadsheet.

[0017] In order to bring an application into focus, or enable the application, the user may select one of the thumbnails. The selection causes the application to become the application in focus.

[0018] In other embodiments, rather than having thumbnails in a grid style, various navigator entities an include icons or text or other combinations to identify the various applications, either potentially to be launched or already running, to a user. The present disclosure is not meant to be limited to any particular representation of applications to a user.

[0019] Reference is now made to Figure 2. Figure 2 shows a mobile device 100 on which there has been no activity for a particular amount of time. In this case, the user interface 110 has been locked by the navigation entity and the user is required to enter a password to unlock the device, as is shown by password prompt 210. In this case, the entire device is locked and password entry is prompted to access both personal and corporate data.

[0020] Referring to Figure 3A, Figure 3A shows an embodiment in which the mobile device 100 has user interface 110 showing the applications already
running or capable of being launched. As with Figure 1, the embodiment of Figure 3A shows a grid style navigation in which various applications can be selected and thumbnails of the current screen on those applications is shown. However, the embodiment of Figure 3A has had a period of inactivity in which work/corporate applications have been locked. In the embodiment of Figure 3A, applications 120, 122, 126 and 130 are personal applications and are shown as being selectable to a user.

[0021] Conversely, applications 124 and 128 have now been made inaccessible and would require password entry in order to access or launch the applications.

[0022] Instead of graying-out or obscuring the application other options are possible. For example, the thumbnails may be provided in a different color. However, if a thumbnail contains a screenshot, sensitive data may be visible even when the device is locked. Thus, the graying-out of the application can provide additional security. Further, in some embodiments, an application that is prevented from being launched or enabled may be hidden until a password or authentication has been successfully entered.

[0023] In other options, instead of providing a gray box, an icon or some other visual display may be provided to a user, and the present disclosure is not meant to be limited to any particular symbol or way or representing or showing restricted access to applications.

[0024] Thus, in the embodiment of Figure 3A, the applications represented by thumbnails 120, 122, 126 and 130 can be launched without any restriction but the applications represented by thumbnails 124 and 128 require a password entry to unlock them.

[0025] Another example cover flow style user interface is shown with regard to Figure 3B. In particular, in Figure 3B, applications 150, 152 and 154 are running. However, due to inactivity, the thumbnails for applications 150 and
154 have been obscured, such as by being blacked out. In the example of Figure 3B, a lock icon is displayed over these application thumbnails.

[0026] Similarly, applications that are considered to be within a class of locked applications will not be permitted to be started by the application launcher. Thus, in the example of Figure 3B, application icons 160, 162, 164, and 166 allow the respective applications to be started. In the example of Figure 3B, however, application icons 162 and 166 are shown obscured, such as being greyed out, indicating that these applications cannot be launched or enabled without receipt of a password, because they are considered to be in the class of locked applications.

[0027] Reference is now made to Figure 4. A navigation entity on the mobile device may track the various applications and determine when they should be locked. One example method of locking the applications at the navigation entity is shown in Figure 4.

[0028] The process of Figure 4 starts at block 410 and proceeds to block 420 in which a timer is reset. The timer represents the maximum inactivity time before applications are locked. The value of the timer at block 420 can be determined by the user, by an IT department from the user's enterprise, or it can be provisioned by a mobile device manufacturer or set by a carrier of a mobile device, among various other options.

[0029] From block 420, the process proceeds to block 422 in which a check is made to determine whether any activity has occurred. If activity has occurred, the process proceeds from block 422 to block 420 in which the timer is reset.

[0030] From block 422, if no activity has occurred on the device the process proceeds to block 424 in which a check is made to determine whether or not the timer has expired. If not, the process proceeds back to block 422 to continue to check for activity and to block 424 to determine whether the timer has expired.
[0031] From block 424, if the timer has expired, the process proceeds to block 430 in which office applications are locked and would require a password to launch the applications. Corporate or work applications may be identified in various ways. For example, the navigation entity can have a list of applications and a flag can be associated with each, where the flag indicates whether or not the application is a corporate application. In other embodiments, the navigation entity can query an enterprise server when locking applications. In other embodiments, a list of applications that are corporate applications can be stored and the navigation entity goes through the list to lock the applications within the list. Other examples of identifying corporate applications are possible.

[0032] The process then proceeds to block 440 and ends.

[0033] The check at block 422 to determine whether activity has occurred may be looking for various activity. In one embodiment, any use of a user interface on the device can be considered to be activity and thus reset the inactivity timer. However, in other embodiments, "activity" may include use of work applications only. Thus, for example, if the user is using a personal application and is not using any work application, the activity check in block 422 may be looking to see whether or not there is activity on the work applications and may cause the work applications to lock even though the user is interacting with the device.

[0034] In other embodiments, each application or class of application can have its own inactivity time before it locks. Thus, applications that are more likely to access more sensitive data can have a shorter inactivity period than other applications that may not be as sensitive.

[0035] Reference is now made to Figure 5. A navigation entity may keep a table or list of the various classes of applications and a lock time for each class. The example of Figure 5 shows a table in which each of the classes 510 is associated with a lock time 520.
[0036] Lock time 520 can be an absolute time at which the class is locked. Alternatively, it can include a timer value or a countdown time.

[0037] For example, in row 530, class XYZ has a lock time represented as an absolute time of 17:36:24, indicating that at 5:36 pm and 24 seconds the application will lock. Column 540 includes a class ABC which has a lock time of 17:28:31 which indicates that at 5:28 and 31 seconds, class ABC will be locked.

[0038] Referring to Figure 6, Figure 6 shows a process for locking the various classes at individual times. The process of Figure 6 starts a block 610 and proceeds to block 612 in which the lock times are reset for those applications or classes that are not already locked.

[0039] The process then proceeds to block 620 in which a check is made to determine whether there is any activity. If yes, the process proceeds back to block 612 in which the lock times are reset for the applications that are not already locked. Thus, referring to Figure 5, the class XYZ may be, for example, the current time plus 5 minutes of inactivity and thus the lock time represented in column 520 can be reset to the current time plus 5 minutes. Similarly, class ABC may be current time plus 3 minutes of inactivity and the lock time in column 520 would be reset to this value.

[0040] From block 620, if there is no activity the process proceeds to block 630 to determine whether or not the time has expired for any class. This can be done by checking the current time against all of the entries in the lock time, for example. In other embodiments, if the column 520 represents a countdown timer then the check at block 630 may include the decreasing of the time and check to see whether or not any of the times have reached zero. Other options are also available.

[0041] From block 630, if no timers have expired the process proceeds back to block 620 and the process continues to check between block 620 and 630 until either activity occurs or until one of the activity timers expires.
[0042] From block 630, the process proceeds to block 632 in which the class or application whose timer has expired is locked. The process then proceeds to block 634 in which a check is made to determine whether there are any other classes or applications which have unexpired lock times. If yes, the process proceeds back to block 620 to either check for activity and continues to check between block 620 and 630 until the remaining timers or times have expired.

[0043] Utilizing the example of Figure 5, if the time for class ABC expires, the process will proceed to block 632 and lock the applications associated with class ABC. At this time, class XYZ is still active and therefore the process will proceed from block 634 back to block 620. In this example, if activity occurs, the process will proceed back to block 612 in which the lock times will be reset. However, since class ABC is already locked, the process will merely reset the lock time for class XYZ.

[0044] From block 634, if all of the lock times have expired, the process will proceed to block 640 and ends.

[0045] The process of Figure 6 can be restarted if the applications are then unlocked.

[0046] The navigation entity will also control the launching or enabling of applications. As used herein, launching applications refers to starting applications that are currently not running. Enabling applications refers to the bringing into focus of currently running applications.

[0047] Reference is now made to Figure 7. In Figure 7, the process starts at block 710 and proceeds to block 720 in which a navigation entity has received a request to launch or enable an application. The process then proceeds to block 730 to check whether or not the application for which the request was received is locked. If no, the process proceeds to block 740 and launches or enables the application.
[0048] Conversely, if the application is locked the process proceeds to block 750 to request the password to unlock the application.

[0049] From block 750 the process proceeds to block 752 to check whether or not the password is correct. If yes, the process proceeds to block 754 in which other locked applications are also unlocked based on the successful password entry and the process then proceeds to block 740 in which the application is launched or enabled.

[0050] From block 752 if the password is not valid the process may proceed to block 760 in which a check is made to determine whether the maximum number of attempts at entering the password has occurred. If no, the process may proceed back to block 750 to prompt the user for a password again.

[0051] From block 760, if the maximum number of password attempts have been made, the process proceeds to block 762 in which security measures are initiated based on the maximum number of attempts being reached. This may include wiping out the memory of the device completely, blocking attempts at access for a predetermined time period, among other options.

[0052] From block 762 or block 740 the process proceeds to block 770 and ends.

[0053] The navigator entity may be found on any computing device. Referring to Figure 8, Figure 8 shows a simplified block diagram of a computing device. In the example of Figure 8, device 810 includes a processor 820. Processor 820 interacts with a navigator entity 830, which may be a software application found on device 810.

[0054] Processor 820 further interacts with an application memory 840. In one embodiment, application memory 840 may be segregated in some embodiments to provide security for locked applications verses unlocked applications. Thus, the two memory areas may be separate and may be
inaccessible by applications that are of different classes. This is similar to, for example, UNIX file permissions in which various group permissions can be set for various applications. In this way, portions of application memory 840 may be inaccessible by non-authorized applications, thereby providing additional security.

[0055] Processor 820 may further communicate with a user interface 850. User interface 850 can comprise any user interface, including, for example, a display on the computing device, audio output means, as well as input means such as a keyboard, mouse, stylus, touch screen, among others. Software for processor 820 may display the various applications on user interface 850. Further, navigator entity 830 may provide that certain application representations on the user interface be displayed as grayed-out or unavailable until a password is entered utilizing the input component of user interface 850.

[0056] While computing device 100 or 810 may be any computing device, as indicated above, in one embodiment computing device 100 or 810 may be a mobile device. One such mobile device is illustrated below with reference to Figure 9. The mobile device of Figure 9 is however not meant to be limiting and other mobile devices may also be used.

[0057] Mobile device 900 may comprise a two-way wireless communication device having voice and data communication capabilities. Mobile device 900 generally has the capability to communicate with other devices or computer systems. Depending on the exact functionality provided, the mobile device may be referred to as a data messaging device, a smartphone a tablet, a computer, a wireless e-mail device, a cellular telephone, a wireless Internet appliance, a wireless device, a user equipment, or a data communication device, as examples.

[0058] Where mobile device 900 is enabled for two-way communication, it will incorporate a communication subsystem 911, including both a receiver 912
and a transmitter 914, as well as associated components such as one or more antenna elements 916 and 918, local oscillators (LOs) 913, and a processing module such as a digital signal processor (DSP) 920. The particular design of the communication subsystem 911 will be dependent upon the communication network in which the device is intended to operate.

[0059] Network access requirements will also vary depending upon the type of network 919. In some networks, network access is associated with a subscriber or user of mobile device 900. A mobile device may require a removable user identity module (RUIM) or a subscriber identity module (SIM) card in order to operate on the network. The SIM/RUIM interface 944 may be similar to a card-slot into which a SIM/RUIM card can be inserted and ejected like a diskette or PCMCIA card. The SIM/RUIM card can have memory and hold many key configuration 951, and other information 953 such as identification, and subscriber related information. A SIM/RUIM is however an optional feature.

[0060] When required network registration or activation procedures have been completed, mobile device 900 may send and receive communication signals over the network 919. As illustrated in Figure 9, network 919 can consist of multiple base stations communicating with the mobile device. For example, in a hybrid CDMA 1x EVDO system, a CDMA base station and an EVDO base station communicate with the mobile station and the mobile device is connected to both simultaneously. In other systems such as Long Term Evolution (LTE) or Long Term Evolution Advanced (LTE-A), multiple base stations may be connected to for increased data throughput. Other systems such as GSM, GPRS, UMTS, HSDPA, among others are possible and the present disclosure is not limited to any particular cellular technology. In other embodiments, the mobile device may communicate with an access point rather than, or in addition to, a cellular network. Such communication may be done using WiFi or WiMAX, for example.

[0061] Signals received by antenna 916 through communication network 919 are input to receiver 912, which may perform such common receiver functions
as signal amplification, frequency down conversion, filtering, channel selection and the like, and in the example system shown in Figure 9, analog to digital (A/D) conversion. A/D conversion of a received signal allows more complex communication functions such as demodulation and decoding to be performed in the DSP 920. In a similar manner, signals to be transmitted are processed, including modulation and encoding for example, by DSP 920 and input to transmitter 914 for digital to analog conversion, frequency up conversion, filtering, amplification and transmission over the communication network 919 via antenna 918. DSP 920 not only processes communication signals, but also provides for receiver and transmitter control. For example, the gains applied to communication signals in receiver 912 and transmitter 914 may be adaptively controlled through automatic gain control algorithms implemented in DSP 920.

[0062] Mobile device 900 generally includes a processor 938 which controls the overall operation of the device. Communication functions, including data and voice communications, are performed through communication subsystem 911. Processor 938 also interacts with further device subsystems such as the display 922, flash memory 924, random access memory (RAM) 926, auxiliary input/output (I/O) subsystems 928, serial port 930, one or more keyboards or keypads 932, speaker 934, microphone 936, other communication subsystem 940 such as a short-range communications subsystem and any other device subsystems generally designated as 942. Serial port 930 may include a USB port or other port known to those in the art.

[0063] Some of the subsystems shown in Figure 9 perform communication-related functions, whereas other subsystems may provide "resident" or on-device functions. Notably, some subsystems, such as keyboard 932 and display 922, for example, may be used for both communication-related functions, such as entering a text message for transmission over a communication network, and device-resident functions such as a calculator or task list, among other applications.
[0064] Operating system software used by the processor 938 may be stored in a persistent store such as flash memory 924, which may instead be a read-only memory (ROM) or similar storage element (not shown). In one embodiment, the operating system, specific device applications, or parts thereof, may be temporarily loaded into a volatile memory such as RAM 926. Received communication signals may also be stored in RAM 926.

[0065] As shown, flash memory 924 can be segregated into different areas for both computer programs 958 and program data storage 950, 952, 954 and 956. These different storage types indicate that each program can allocate a portion of flash memory 924 for their own data storage requirements. This may further provide security if some applications are locked while others are not.

[0066] Processor 938, in addition to its operating system functions, may enable execution of software applications on the mobile device. A predetermined set of applications that control basic operations, including at least data and voice communication applications for example, will normally be installed on mobile device 900 during manufacturing. Other applications can be installed subsequently or dynamically.

[0067] Applications and software, such as those for implements the process of Figure 4 to 7, may be stored on any computer readable storage medium. The computer readable storage medium may be a tangible or intransitory/non-transitory medium such as optical (e.g., CD, DVD, etc.), magnetic (e.g., tape) or other memory known in the art.

[0068] One software application may be a personal information manager (PIM) application having the ability to organize and manage data items relating to the user of the mobile device such as, but not limited to, e-mail, calendar events, voice mails, appointments, and task items. Naturally, one or more memory stores would be available on the mobile device to facilitate storage of PIM data items. Such PIM application may have the ability to send and receive data items, via the wireless network 919. In one embodiment, the
PIM data items are seamlessly integrated, synchronized and updated, via the wireless network 919, with the mobile device user's corresponding data items stored or associated with a host computer system. Further applications, such as a media player; a camera; a messenger; mail; social networking; a web browser; games; electronic book readers; wallet; maps, among others, may also be loaded onto the mobile device 900 through the network 919, an auxiliary I/O subsystem 928, serial port 930, short-range communications subsystem 940 or any other suitable subsystem 942, and installed by a user in the RAM 926 or a non-volatile store (not shown) for execution by the processor 938. Such flexibility in application installation increases the functionality of the device and may provide enhanced on-device functions, communication-related functions, or both. For example, secure communication applications may enable electronic commerce functions and other such financial transactions to be performed using the mobile device 900.

[0069] In a data communication mode, a received signal such as a text message or web page download will be processed by the communication subsystem 911 and input to the processor 938, which may further process the received signal for output to the display 922, or alternatively to an auxiliary I/O device 928.

[0070] A user of mobile device 900 may also compose data items such as email messages for example, using the keyboard 932, which may be a complete alphanumeric keyboard or telephone-type keypad, among others, in conjunction with the display 922 and possibly an auxiliary I/O device 928. Such composed items may then be transmitted over a communication network through the communication subsystem 911.

[0071] For voice communications, overall operation of mobile device 900 is similar, except that received signals would typically be output to a speaker 934 and signals for transmission would be generated by a microphone 936. Alternative voice or audio I/O subsystems, such as a voice message recording subsystem, may also be implemented on mobile device 900. Although voice or audio signal output is preferably accomplished primarily
through the speaker 934, display 922 may also be used to provide an indication of the identity of a calling party, the duration of a voice call, or other voice call related information for example.

[0072] Serial port 930 in Figure 9 would normally be implemented in a personal digital assistant (PDA)-type mobile device for which synchronization with a user’s desktop computer (not shown) may be desirable, but is an optional device component. Such a port 930 would enable a user to set preferences through an external device or software application and would extend the capabilities of mobile device 900 by providing for information or software downloads to mobile device 900 other than through a wireless communication network. The alternate download path may for example be used to load an encryption key onto the device through a direct and thus reliable and trusted connection to thereby enable secure device communication. Serial port 930 can further be used to connect the mobile device to a computer to act as a modem.

[0073] Other communications subsystems 940, such as a short-range communications subsystem, is a further optional component which may provide for communication between mobile device 900 and different systems or devices, which need not necessarily be similar devices. For example, the subsystem 940 may include an infrared device and associated circuits and components or a Bluetooth™ communication module to provide for communication with similarly enabled systems and devices.

[0074] The embodiments described herein are examples of structures, systems or methods having elements corresponding to elements of the techniques of this application. This written description may enable those skilled in the art to make and use embodiments having alternative elements that likewise correspond to the elements of the techniques of this application. The intended scope of the techniques of this application thus includes other structures, systems or methods that do not differ from the techniques of this application as described herein, and further includes other structures, systems
or methods with insubstantial differences from the techniques of this application as described herein.
CLAIMS

1. A method for providing differentiated access control on a mobile device, the method comprising:
   starting a timer on the mobile device, the timer being an inactivity timer for a subset of applications selected from a plurality of applications on the mobile device;
   resetting the timer if activity occurs on the mobile device prior to the expiration of the timer; and
   preventing each application of the subset of applications from being launched or enabled on the mobile device upon expiry of the timer, the preventing further comprising changing a graphical representation of an application thumbnail or icon of each application of the subset of applications on the mobile device, the changing the graphical representation showing each application of the subset of applications is locked, while applications on the mobile device other than those in the subset of applications remain unlocked.

2. The method of claim 1, wherein the subset of applications on the mobile device utilize a separate file system from other applications in a memory of the mobile device.

3. The method of claim 1 or claim 2, wherein the graphical representation is a grid style and the changing replaces the application thumbnail with an obscured out or locked graphic.

4. The method of claim 3, wherein selection of the obscured graphic initiates a password prompt.

5. The method of any one of claims 1 to 4, wherein the timer has a plurality of expiry times for different subsets of applications.

6. The method of any one of claims 1 to 5, wherein the subset of applications is designated as corporate applications.

7. The method of claim 6, wherein the designating is based on an enterprise information technology policy.

8. The method of claim 6, wherein the designating is done on the mobile device.
9. The method of any one of claims 1 to 8, wherein activity occurring on the mobile device includes any interacting with a user interface on the mobile device.

10. The method of any one of claims 1 to 8, wherein activity occurring on the mobile device includes only interaction with any one of the subset of applications.

11. The method of any one of claims 1 to 10, further comprising unlocking each application in the subset of applications in response to successful authentication.

12. The method of any one of claims 1 to 11, further comprising preventing each application in the subset of applications whose timer has expired from being launched or enabled, while allowing the launching or enablement of one or more applications associated with another subset of applications.

13. A mobile device comprising:
a processor;
a user interface; and
memory,
wherein the processor is enabled to:

start a timer on the mobile device, the timer being an inactivity timer for a subset of applications selected from a plurality of applications on the mobile device;
reset the timer if activity occurs on the mobile device prior to the expiration of the timer; and
prevent each application of the subset of applications from being launched or enabled on the mobile device upon expiry of the timer, wherein the processor, user interface and memory further cooperate to prevent by changing a graphical representation of an application thumbnail or icon of each application of the subset of applications displayed on the mobile device, the changing the graphical representation showing each application of the subset of applications is locked, while applications on the mobile device other than those in the subset of applications remain unlocked.

14. The mobile device of claim 13, wherein the subset of applications on the mobile device utilize a separate file system from other applications in a memory of the mobile device.
15. The mobile device of claim 13 or claim 14, wherein the graphical representation is a grid style and the changing replaces the application thumbnail with an obscured or locked graphic.

16. The mobile device of claim 15, wherein selection of the obscured or locked graphic on the user interface initiates a password prompt.

17. The mobile device of any one of claims 13 to 16, wherein the timer has a plurality of expiry times for different subsets of applications.

18. The mobile device of any one of claims 13 to 17, wherein the subset of applications are designated as corporate applications.

19. The mobile device of claim 18, wherein the designating is made based on an enterprise information technology policy.

20. The mobile device of claim 18, wherein the designating is done on the mobile device.

21. The mobile device of any one of claims 13 to 20, wherein activity occurring on the mobile device includes any interaction with the user interface.

22. The mobile device of any one of claims 13 to 20, wherein activity occurring on the mobile device includes only interaction with the subset of applications.

23. The mobile device of any one of claims 13 to 22, wherein the mobile device comprises at least one of a smartphone, a tablet computer, or a laptop computer.

24. A computer readable medium storing instructions that when executed by a processor of a mobile device cause the mobile device to perform operations comprising:

starting a timer on the mobile device, the timer being an inactivity timer for a subset of applications selected from a plurality of applications on the mobile device;

resetting the timer if activity occurs on the mobile device prior to the expiration of the timer; and

preventing each application of the subset of applications from being launched or enabled on the mobile device upon expiry of the timer, the preventing further comprising changing a
graphical representation of an application thumbnail or icon of each application of the subset of applications on the mobile device, the changing the graphical representation showing each application of the subset of applications is locked, while applications on the mobile device other than those in the subset of applications remain unlocked.

25. The computer readable medium of claim 24, wherein the subset of applications on the mobile device utilize a separate file system from other applications in a memory of the mobile device.

26. The computer readable medium of claim 24 or claim 25, wherein the graphical representation is a grid style and the changing replaces the application thumbnail with an obscured out or locked graphic.

27. The computer readable medium of claim 26, wherein selection of the obscured graphic initiates a password prompt.

28. The computer readable medium of any one of claims 24 to 27, wherein the timer has a plurality of expiry times for different subsets of applications.

29. The computer readable medium of claim 28, wherein the subset of applications is designated as corporate applications.

30. The computer readable medium of claim 29, wherein the designating is based on an enterprise information technology policy.

31. The computer readable medium of claim 29, wherein the designating is done on the mobile device.

32. The computer readable medium of any one of claims 24 to 31, wherein activity occurring on the mobile device includes any interacting with a user interface on the mobile device.

33. The computer readable medium of any one of claims 24 to 31, wherein activity occurring on the mobile device includes only interaction with any one of the subset of applications.
34. The computer readable medium of any one of claims 24 to 33, the operations further comprising unlocking each application in the subset of applications in response to successful authentication.

35. The computer readable medium of any one of claims 24 to 34, the operations further comprising preventing each application in the subset of applications whose timer has expired from being launched or enabled, while allowing the launching or enablement of one or more applications associated with another subset of applications.
