A stamped jaw for use in an endoscopic device. The jaw includes a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between the side walls. The opposite side walls have a first tooth profile and the end wall has a second tooth profile different from the first tooth profile.

## ENDOSCOPIC DEVICE

### BACKGROUND OF THE INVENTION

[0001] The present invention generally relates to endoscopic instruments, and more particularly to biopsy forceps and other endoscopic end effectors.

[0002] Endoscopic biopsy forceps are a medical instrument used in combination with an endoscope for removing tissue samples from inside a patient's body for analysis. These instruments typically include an elongate flexible member having a biopsy jaw assembly mounted on one end. The jaw assembly includes a clevis holding pivotally mounted jaws adapted for removing tissue for analysis. An actuator comprising an actuator handle and an actuator member extending from the handle to the pivoting jaws of the jaw assembly moves the jaws between an open position in which the ends of the jaws are spaced and a closed position in which the ends of the jaws contact each other to obtain the tissue sample. In addition to biopsy forceps, some aspects of the present invention relate to other types of endoscopic end effectors such as a flexible grasper, a dissector, or scissors.

[0003] Biopsy forceps frequently have teeth along the mating edges of the jaws to improve grasping of the tissue. As will be appreciated by those skilled in the art, the teeth extending along each side of the jaw and those extending across the end of the jaw interact differently with the tissue. In the past, these differences in interaction have not been taken into account when selecting tooth profiles for the different portions of the jaw. A fundamental function of biopsy forceps is to pinch tissue in order to tear a sample free. The teeth, particularly those at the end of the jaw, are believed to have a significant impact on sample depth and weight.

[0004] Many conventional jaws have been made so that each jaw in the assembly has a different configuration. When a single jaw assembly uses two different jaw configurations, the different jaws must be manufactured, stored and handled during assembly. This situation results in manufacturing inefficiency and a cost increase. In addition, many conventional jaws are cast or molded. Jaws designed to be manufactured using other less expensive processes have the potential for reducing overall assembly cost.

[0005] Because the jaw assembly includes a clevis, certain obstacles are presented during assembly. If the clevis and axle pin are inseparably assembled before the jaws are installed, the arms of the clevis must be spread when the jaws are being assembled with the clevis. If the clevis and axle pin are separate, the jaws must be inserted between the clevis arms and aligned with the axle pin. Either process has a potential for increasing assembly cost. Still further, connecting the actuator members to the jaw assembly is difficult to achieve using conventional devices because the clevis blocks clear access to these components.

[0006] Once assembled, the jaw assembly has portions (e.g., distal portions) that are susceptible to higher stresses and wear. In order to optimize the jaw, some portions of the jaw can be thicker or made from different materials. Although producing a jaw cup by stamping has economic advantages, conventional jaw assemblies have been unable to take advantage of a stamped jaw cup while having thicker portions or portions made from different materials.

[0007] During use, a large jaw size is desired to obtain a large tissue sample. However, when the forceps are being pushed into position, a small jaw size is desirable so that the forceps can travel through smaller radius turns. Using conventional jaw shapes, the jaw size is limited by turning radius.

[0008] Among the problems common to known biopsy forceps and end effectors generally is that these instruments are very long and flexible, making packaging, storage and handling difficult. The instruments are frequently coiled when packaged. When the packaging is opened, the instruments can spontaneously uncoil, become unmanageable, potentially falling on the floor, and becoming contaminated or being damaged. Thus, there is a need for a feature that retains these types of instruments in a coiled configuration when unpackaged.

### SUMMARY OF THE INVENTION

[0009] Briefly, the present invention includes a stamped jaw for use in an endoscopic device. The jaw comprises a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between the side walls. The opposite side walls have a first tooth profile and the end wall has a second tooth profile different from the first tooth profile.

[0010] In another aspect, the invention includes a jaw for use in an endoscopic device comprising a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between the side walls. The end wall has a sinusoidal tooth profile.

[0011] The invention also includes an endoscopic device comprising an elongate member having opposite ends. And a pair of jaws mounted for pivotal movement on one end of the opposite ends. Each jaw includes a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between the side walls. The opposite side walls have a first tooth profile and the end wall has a second tooth profile different from the first tooth profile. The device also comprises an actuator member operatively connected to the pair of jaws for moving the jaws between a closed position in which the end of the corresponding jaw is positioned adjacent the other jaw and an open position in which an end of the jaw is spaced from the other jaw.

[0012] Other features of the present invention will be in part apparent and in part pointed out hereinafter.

### BRIEF DESCRIPTION OF THE DRAWINGS

[0013] FIG. 1 is a side elevation of biopsy forceps of the present invention;

[0014] FIG. 2 is a partially disassembled side elevation of a handle assembly of the biopsy forceps;

[0015] FIG. 3 is a perspective of biopsy forceps of the present invention;

[0016] FIG. 4 is a perspective of a portion of the handle assembly of the biopsy forceps;

[0017] FIG. 5 is a detail in partial section of the handle assembly of the biopsy forceps;

[0018] FIG. 6 is a cross section of a jaw assembly of the biopsy forceps showing jaws in an open position;

[0019] FIG. 7 is a cross section of the jaw assembly showing jaws in a closed position;

[0020] FIG. 8 is a perspective of the jaw assembly of the biopsy forceps showing jaws in an open position;

[0021] FIG. 9 is a perspective of a jaw of the jaw assembly;

[0022] FIG. 10 is a perspective of a first alternative clevis;

[0023] FIG. 11 is a perspective of a second alternative clevis;

[0024] FIG. 12 is a perspective of a third alternative clevis;

[0025] FIG. 13 is a perspective of a fourth alternative clevis

[0026] FIG. 14 is a perspective of a first alternative jaw;

[0027] FIG. 15 is a top plan of a second alternative jaw;

[0028] FIGS. 16A and 16B are top plans of first and second alternative actuator members, respectively;

[0029] FIG. 17 is a perspective of a second alternative actuator member and jaw;

[0030] FIG. 18 is a top plan of a third alternative jaw;

[0031] FIG. 19 is a perspective of a fourth alternative jaw;

[0032] FIG. 20 is an alternate perspective of the fourth alternative jaw; and.

[0033] FIGS. 21A-E illustrate a sequence of movements used to prepare the instrument for packaging using one method.

[0034] Corresponding reference characters indicate corresponding parts throughout the several views of the drawings.

#### Detailed Description of the Preferred Embodiment

[0035] Referring now to the drawings and in particular to FIG. 1, a surgical instrument of the present invention is designated in its entirety by the reference numeral 30. Although the surgical instrument 30 illustrated in FIG. 1 is a pair of biopsy forceps, in some embodiments of the present invention the surgical instrument may be a different type of endoscopic end effector such as a flexible grasper, a dissector or scissors. In the case of the biopsy forceps embodiment, the surgical instrument 30 is used to sample tissue (not shown) of a patient during surgery or endoscopy. The instrument 30 generally comprises an elongate member, generally designated by 32, having opposite ends 34, 36. A jaw assembly, generally designated by 40, is mounted on the elongate member 32 adjacent its end 34. The jaw assembly 40 includes jaws 42 mounted for independent pivotal movement relative to each other between a closed position (FIG. 7) for grasping tissue and an open position (FIG. 6 showing a partially open position) for releasing tissue. As further shown in FIG. 1, the instrument 30 comprises an actuator assembly, generally designated by 44, including an actuator member 46 operatively connected to the jaw assembly 40 for moving the jaws 42 between the open and closed positions, and a handle assembly, generally designated by 50, operatively connected to the actuator member. Although the actuator member 46 may be made of other materials without departing from the scope of the present invention, in one embodiment the member 46 is a tube having an inner

diameter of between about 0.020 inch and about 0.030 inch crimped to hold a pair of wires having outer diameters of between about 0.010 inch and about 0.012 inch. Although the tube and wires may be made of other materials without departing from the scope of the present invention, in one embodiment they are made from 304 stainless steel. Although the tube may have other dimensions without departing from the scope of the present invention, in one embodiment the tube has an overall length of between about two inches and about three inches and an outer diameter of between about 0.030 inch and about 0.040 inch.

[0036] As illustrated in FIG. 2, the handle assembly 50 includes a hollow shank 52 having an elongate slot 54 extending partially along its length. A spool, generally designated by 56, is slidably mounted on the shank 52 and a thumb ring 58 is provided at an end of the shank opposite the elongate member 32 for receiving a surgeon's thumb during use. A C-clip fastener 60 is provided on the thumb ring 58 for releasably connecting the elongate member 32 to the handle assembly 50 during storage and packaging as illustrated in FIG. 3. Although other fastener types may be used without departing from the scope of the present invention, in one embodiment the fastener is a C-clip integrally molded on a proximal end of the thumb ring. The spool 56 is formed in two halves joined by press pins 62 as shown in FIG. 2. In one particular embodiment, each press pin 62 has a circular cross section and is positioned in a hexagonal hole. In an alternative embodiment, the spool 56 is held together with adhesives, with screws or with detent fasteners. When assembled, the spool 56 includes an annular groove 64 formed between circumferentially extending ribs 66, 68. In use, the surgeon holds the spool 56 between his/her index finger and middle finger so that the fingers are positioned in the annular groove 64. The surgeon's thumb is inserted in the thumb ring 58. The spool 56 may be moved toward and away from the thumb ring 58 by pulling or pushing the fingers against the ribs 66, 68, respectively. Although the shank 52 and spool 56 may be made from other materials without departing from the scope of the present invention, in one embodiment the shank and spool are made from a polymer such as polycarbonate, polypropylene or ABS.

[0037] As illustrated in FIG. 4, a retainer 70 is captured in a recess 72 formed in the spool 56 halves. The retainer 70 includes a slot 74 for receiving a bent end 76 of the tube portion of the actuator member 46. The tubing 78 reinforces the actuator member 46. Thus, as the spool 56 is moved back and forth relative to the shank 52, the actuator member 46 slides back and forth in the elongate member 32 of the instrument 30. Although the retainer 70 may be made of other materials without departing from the scope of the present invention, in one embodiment the retainer is made of 400 series stainless steel.

[0038] As illustrated in FIG. 5, the shank 52 of the handle assembly 50 includes a connector portion, generally designated by 80. The connector portion 80 includes a bore 82. During assembly, the end 36 of the elongate member 32 is inserted in the bore 82. A ferrule 84 is crimped around the elongate member 32. The ferrule 84 includes barbs (not shown) that prevent the member from being withdrawn from the bore 82. Accordingly, the elongate member 32 is firmly connected to the handle assembly 50 so they form an inseparable assembly. Although the ferrule 84 may be made of other materials without departing from the scope of the

present invention, in one embodiment the ferrule is made of brass. Further, although the ferrule **84** may have other dimensions without departing from the scope of the present invention, in one embodiment the ferrule has an overall length of between about 0.75 inch and about 1.25 inches, an undeformed inner diameter of between about 0.075 inch and about 0.095 inch, and an undeformed outer diameter of between about 0.100 inch and about 0.150 inch.

[0039] As shown in FIG. 6, the elongate member **32** comprises a coil **90** having an outer cover **92** and an inner lumen **94**. Although the coil **90** may be made of other materials, in one embodiment the coil is made from 302 stainless steel. Although the coil may have other maximum outer diameters without departing from the scope of the present invention, in one embodiment the coil has a maximum outer diameter of between about 0.070 inch and about 0.080 inch. In one particular embodiment, the coil has a maximum outer diameter of about 0.074 inch. Although the coil **90** may have other configurations without departing from the scope of the present invention, in one embodiment the coil has a generally circular cross section and a generally uniform outer diameter. So the coil **90** has sufficient stiffness, the coil may be made so it has compressive preload. Although the coil **90** may have other compressive preloads without departing from the scope of the present invention, in one embodiment the coil has a compressive preload of between 0.75 pound and about 1.5 pounds. In other words, a tensile load of between about 0.75 pound and about 1.5 pounds is required to separate windings of the coil **90**. In one particular embodiment, the coil **90** has a compressive preload of about 1.3 pounds.

[0040] Likewise, although the outer cover **92** may be made of other materials without departing from the scope of the present invention, in one embodiment the outer cover is made from polyolefin. Although the inner lumen **94** may be made of other materials without departing from the scope of the present invention, in one embodiment the inner lumen is made from high density polyethylene. Although the coil **90** may have other dimensions without departing from the scope of the present invention, in one embodiment the coil has an overall length of between about 220 centimeters and about 260 centimeters, an outer diameter of between about 0.070 inch and about 0.080 inch, and an inner diameter of between about 0.035 inch and about 0.040 inch. The coil **90** is made from wire stock having a diameter of between about 0.015 inch and about 0.020 inch. Further, although the outer cover **92** may have other outer diameters without departing from the scope of the present invention, in one embodiment the outer cover has an outer diameter of between about 0.085 inch and about 0.92 inch. Although the inner lumen **94** may have other inner diameters without departing from the scope of the present invention, in one embodiment the inner lumen has an inner diameter of between about 0.020 inch and about 0.035 inch. As the elongate member **32** is generally conventional, it will not be described in further detail.

[0041] As further illustrated in FIG. 6 as well as in FIG. 7, the jaw assembly **40** includes a clevis, generally designated by **100**, mounted on the end **34** of the elongate member **32**. As shown in FIG. 8, the clevis includes two arms **102** extending generally parallel to each other from a barrel **104**. Each of the arms **102** includes a pivot hole for receiving an axle pin **106** therein so that the axle pin extends between the arms. The axle pin **106** pivotally connects the jaws **42** of the

jaw assembly **40** to the clevis **100**. In addition, the axle pin **106** may connect a central needle **110** to the clevis **100**. The needle **110** includes a sharp point **112** for penetrating tissue (not shown). As shown in FIG. 6, the needle **110** also includes an opening **114** for receiving the axle pin **106**. The needle **110** also includes a lobe **116** opposite the point **112** for engaging the jaws **42** to hold the needle in a centered position between the jaws as will be explained in further detail below. Although the clevis **100** may be made of other materials without departing from the scope of the present invention, in one embodiment the clevis is made from 17-7 PH stainless steel. Although the axle pin **106** may be made of other materials without departing from the scope of the present invention, in one embodiment the axle pin is made from 304 stainless steel. Although the needle **110** may be made of other materials without departing from the scope of the present invention, in one embodiment the needle is made from 302 stainless steel.

[0042] Using one assembly method, the clevis **100** is positioned in a fixture (not shown). The jaws **42** and the needle **110** are positioned between the arms **102** of the clevis **100** and the axle pin **106** is inserted through the holes in the clevis, jaws and needle. The axle pin **106** is biased toward one side of the holes in the clevis **100** and joined to the clevis using a conventional method such as welding, swaging or riveting.

[0043] As illustrated in FIG. 9, each of the jaws **42** includes a cup **120** having opposite side walls **122** extending longitudinally along the respective jaw and an end wall **124** extending across corresponding forward ends of the side walls. In one embodiment, the side walls **122** and end wall **124** extend generally perpendicular to a central land **126** of the cup **120**. In addition, each jaw **42** includes a hinge extension **130** extending from one of the side walls **122**. Although the jaw **42** may have other configurations without departing from the scope of the present invention, in one embodiment the other side wall **122** opposite that having the hinge extension **130** is substantially free of extensions. The hinge extension **130** extends to a pivot hole or opening **132** adapted for receiving the axle pin **106** extending between the arms **102** of the clevis **100**. Although the jaws **42** may have differing configurations without departing from the scope of the present invention, in one embodiment both jaws **42** are identical to reduce manufacturing costs. In one embodiment, the hinge extension **130** includes an inner face **134** surrounding the opening **132**. Further, in one embodiment with the central needle **110**, the inner face **134** is offset from an imaginary median plane of the jaws **42** by a distance equal to half a thickness of the central needle. In an alternate embodiment (not shown) that does not include a central needle, the inner face is positioned on the imaginary median plane of the jaws.

[0044] The jaw **42** also includes an outer face **136** positioned to abut the clevis **100** when assembled in the biopsy forceps **30**. The side walls **122** have a common tooth profile and the end **124** wall has a tooth profile different from the side wall tooth profile. Although the jaw **42** maybe formed in other ways, in one embodiment, each jaw is stamped from sheet metal and formed to shape. Although the jaws **42** may be made of other materials without departing from the scope of the present invention, in one embodiment the jaws are made from 17-7 PH stainless steel. In one particular embodiment, the hinge extension **130** includes a folded portion

forming the inner face **134** extending along the median plane and the outer face **136** positioned to abut the clevis **100** when assembled in the biopsy forceps **30**. Although hinge extension **130** may be folded in other ways without departing from the scope of the present invention, in one embodiment the extension is folded along a substantially straight fold extending parallel to a longitudinal axis of the jaw. Each jaw **42** also includes a control arm **140** for pivoting the respective jaw about the axle pin **106**. Although the control arm **140** may have other configurations, in one embodiment the control arm is integrally formed as part of the hinge extension **130**. The control arm **140** includes an actuation hole or opening **142** for receiving the actuator member **46**. In one embodiment, each cup **120** includes an opening **144** allowing the respective cup to drain.

[0045] An alternative embodiment of the clevis is generally designated by the reference number **200** in FIG. **10**. The clevis **200** is formed in two pieces **202**. Each piece includes a barrel portion **204** for engaging the end **34** of the elongate member **32**. Each clevis half **202** further includes an arm **206**. Each arm **206** includes a hole **208** for receiving the axle pin **106** therein. To assemble the jaw assembly **40** using the alternate clevis embodiment shown in FIG. **10**, one of the clevis halves **202** is joined to an axle pin **106** to form a master clevis piece. The master clevis piece is held in position against the end **34** of the elongate member **32** and the jaws **42** and needle **110** are mounted on the axle pin **106**. The second half of the clevis **202** is placed over the first half and the axle pin **106** is laser welded to the corresponding hole **208** in the clevis arm **206**. The barrels **204** of the clevis halves **202** are simultaneously welded (e.g., laser welded) to the end **32** of the elongate member **32**. It is envisioned that this assembly method would simplify the assembly process even when additional components (not shown) such as spacers and spring washers are added to the assembly. Because the clevis **200** is split, component tolerances may be larger. As other features of the clevis **200** are identical to those described above, they will not be described in further detail.

[0046] FIG. **11** shows a second alternative embodiment of a clevis generally designated by the referenced number **210**. This embodiment of the clevis **210** is identical to the first alternative embodiment of the clevis **200** described above except that one clevis half **212** includes protrusions such as rectangular tabs **214** extending from its barrel **216**. The barrel **218** of the other half includes recesses such as rectangular notches **220** for accommodating the tabs **214**. This second alternative embodiment allows for one clevis half to extend more than half way around the end **34** of the elongate member **32** to aid in holding the clevis half in place during assembly. The tabs **214** and notches **220** also constitute alignment features that aid in locating the second clevis half. In a variation on this alternative embodiment, a notch or other locating feature may be included on the barrel of the clevis **210** for aligning the clevis with the end **34** of the elongate member **32**. Because other features of the clevis **210** are identical to those described above, they will not be described in further detail.

[0047] Both of the devices described above are assembled using a similar method. A first clevis half is positioned in a fixture (not shown). The jaws are positioned on the first clevis half and if a central needle is used it is positioned between the jaws. A second clevis half is positioned on the

jaw assembly. The stacked components are squeezed together by the fixture and then the fixture is relaxed so that a total accumulated stack gap between the components is within a tolerance selected to assure proper operation of the jaws. Although other accumulated gaps may be used without departing from the scope of the present invention, in one embodiment the accumulated gap is between about 0.0005 inch and about 0.003 inch. After the stack gap is adjusted, a pivot member or pivot pin is inserted through the components and fastened in place. The actuator member may be connected to the jaws at a convenient time during the assembly.

[0048] A third alternative embodiment is generally designated by the reference number **230** in FIG. **12**. This third alternative embodiment of the clevis **230** is identical to the first alternative embodiment **200** illustrated in FIG. **10** except that the clevis halves are joined on one side, leaving a slot **232** along one side. In one embodiment of the third alternative clevis **230**, the jaw assembly **42** is assembled without assembling the clevis **230** to the end **34** of the elongate member **32**. This jaw assembly **42** may be manufactured remote from the overall instrument. The slot **232** has an advantage of aiding in inserting the actuation member **46** during assembly. Other features of the clevis **230** are identical to those described above and will not be described in further detail.

[0049] FIG. **13** illustrates a fourth alternative embodiment generally designated by the reference number **234**. The fourth alternative embodiment of the clevis **234** is identical to the third alternative embodiment **230** except that the clevis includes arms **236** having folded portion **238**. Other features of the clevis **234** are identical to those described above and will not be described in further detail.

[0050] The devices described above having joined halves are assembled similarly to the previously described method except that the first and second clevis halves are simultaneously positioned on the fixture and the jaws and needle are inserted between the arms of the clevis during assembly rather than stacked in sequence. Other aspects of the assembly method are identical and will not be described in further detail.

[0051] FIG. **14** illustrates an alternative embodiment of a jaw **240**. The jaw **240** is identical to the previously discussed jaw **42** except that the end wall **242** has a sinusoidal tooth profile and the drain hole **144** is omitted. The side walls **122** (FIG. **9**) of this embodiment have a tooth profile that is generally uniform and repeating. For example, the side wall tooth profile has generally saw tooth shape. Further, as will be appreciated by examining FIG. **14**, the spacing of tooth profile of the end wall **242** is longer than that of the tooth profile of the side walls **122**. FIG. **15** discloses a second alternative embodiment of the jaws, generally designated **250**. The second alternative embodiment of the jaw **250** is similar to the first embodiment of the jaw **42** described above except that the folded portion of the hinge extension **130** is replaced with an embossed portion **252**. This embossed portion **252** is positioned longitudinally between two other portions **254**, **256**. The embossed portion **252** includes an inner face extending along the median plane. The other portions **254**, **256** include the outer face positioned to abut the clevis **100** when assembled in the biopsy forceps **30**. Because other features of the jaws are identical to those described above, they will not be described in further detail.

[0052] FIG. 16A illustrates a partial jaw assembly and an alternative embodiment of an actuator member 270. The actuator member 270 comprises an actuator wire having a helical portion 272 for connecting the actuator member to the control arm 140 of the jaw 42. The helical portion 272 of the actuation wire 270 permits the wire to be easily threaded into the opening 142 in the control arm 140 of the jaw 42 to save assembly time and eliminate other processes for connecting the wire to the control arm (e.g., heading). FIG. 16B illustrates a partial jaw assembly and a second alternative embodiment of an actuator member 270. The actuator member 270 comprises an actuator wire having a helical portion 274 similar to that of the previously described embodiment except that the helical portion of the second alternative embodiment is wound about a lateral axis rather than a longitudinal axis. In a third alternative embodiment illustrated in FIG. 17, the actuation wire 276 includes a bent end 278. A U-shaped tang 280 formed on the jaw 282 adjacent the control arm opening 142 retains the actuation wire 276 in position in the control arm opening. To assemble the actuation wire 276 of the second alternative embodiment, the bent end 278 of the wire 276 is inserted in the opening 142 and then the jaw 282 is rotated relative to the wire so the tang 280 engages the wire to prevent removal of the bent portion of the wire from the opening. As other features of the actuator members and jaws of these embodiments are identical to those described above, they will not be described in further detail.

[0053] FIG. 18 illustrates an alternative embodiment of a jaw, generally designated by 290. Rather than having an integral cup and hinge extension, the jaw 290 of this alternative embodiment is made from separate pieces. The jaw has a cup 292 with a pair of hinge connectors 294 extending from it for joining a hinge extension 296 to the cup. The hinge extension 296 maybe connected to the hinge connector 294 by any suitable means such as laser welding or adhesives. As will be apparent to those skilled in the art, the jaw cup 292 of the alternative embodiment has a different shape than those disclosed above. The primary difference between the jaw cup 292 shown in FIG. 18 and those previously disclosed is that the side walls are spaced farther from the median plane at a position between the front end and the back end than at the front end and at the back end. This configuration permits the end effector to travel through tighter radiuses without binding. The jaw cup of this embodiment permits a larger volume of tissue to be removed while maintaining the same minimal bend radius. Cups having other shapes are also envisioned as being within the scope of this embodiment. For example, rather than having an oval shape as shown, the cup may have an hourglass shape or a tapered shape.

[0054] FIG. 19 illustrates a second alternative embodiment of a jaw 300 that maximizes tissue volume removed. In this embodiment, the end wall 302 has a substantially plainer portion so the cup encompasses a generally rectilinear volume. FIG. 20 illustrates an alternate view of the jaw illustrated in FIG. 19. The jaw 300 maybe formed in two pieces, a cup 304 and a hinge extension 306. The cup 304 maybe formed from sheet metal and the hinge extension 306 maybe formed of a polymer such as glass filled nylon. One benefit of this design is that the hinge extension 306 may have molded features (e.g., bushing 308) rather than a substantially constant thickness. This provides additional material where stresses are higher or where wear is likely to

occur. In addition, the two piece design permits the use of different materials in different parts of the jaw 300 to optimize the design. The cup 304 and hinge extension 306 may be joined by any conventional means. For example, the cup 304 and hinge extension 306 may be joined by heating the hinge extension so that it is molded into holes 310 formed in the cup to mechanically join the components.

[0055] The instrument described above may be wound in a conventional manner prior to packaging. One method of preparing the instrument for packaging is particularly advantageous because it reduces the likelihood of the instrument becoming tangled and/or springing apart so it is damaged or contaminated. The effector assembly is fastened to the handle to form a first loop as illustrated in FIG. 21a. The loop is grasped at opposite ends and one end is twisted relative to the other through an angle of about 180 degrees to move the loop into a figure-8 configuration as illustrated in FIG. 21b. Opposite ends of the figure-8 configuration are moved together into an overlapped loop configuration shown in FIG. 21c. The overlapping loop is grasped at opposite ends and one end is twisted relative to the other through an angle of about 180 degrees to move the loop into a double figure-8 configuration as illustrated in FIG. 21d. In one embodiment, the ends of the overlapped loop are twisted in a direction opposite to that which the loop was previously twisted as shown by the arrows in FIGS. 21b and 21d. Lastly, opposite ends of the double figure-8 configuration are folded together to move the double figure-8 configuration into a quadruple overlapped loop configuration as illustrated in FIG. 21e. The instrument in this final configuration may be packaged in a conventional sterile packaging.

[0056] When introducing elements of the present invention or the preferred embodiment(s) thereof, the articles “a”, “an”, “the” and “said” are intended to mean that there are one or more of the elements. The terms “comprising”, “including” and “having” are intended to be inclusive and mean that there may be additional elements other than the listed elements.

[0057] As various changes could be made in the above constructions without departing from the scope of the invention, it is intended that all matter contained in the above description or shown in the accompanying drawings shall be interpreted as illustrative and not in a limiting sense.

What is claimed is:

1. A stamped jaw for use in an endoscopic device, said jaw comprising:

a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between said side walls, wherein the opposite side walls have a first tooth profile and the end wall has a second tooth profile different from the first tooth profile.

2. A jaw as set forth in claim 1 wherein said second tooth profile has a shape different from that of said first tooth profile.

3. A jaw as set forth in claim 1 wherein said first tooth profile is generally uniform and repeating.

4. A jaw as set forth in claim 1 wherein said first tooth profile comprises a saw tooth shape.

5. A jaw as set forth in claim 4 wherein said second tooth profile comprises a sinusoidal shape.

6. A jaw as set forth in claim 1 wherein said second tooth profile comprises a sinusoidal shape.

7. A jaw as set forth in claim 1 wherein said second tooth profile has a spacing different from that of said first tooth profile.

8. A jaw as set forth in claim 7 wherein the spacing of said second tooth profile is longer than that of said first tooth profile.

9. A jaw as set forth in claim 7 wherein the spacing of said first tooth profile has a generally uniform spacing.

10. A jaw as set forth in claim 1 wherein:

the jaw includes a pivot and a nominal jaw height aligned with the pivot;

the first tooth profile extends above and below the nominal jaw height; and

the second tooth profile extends above and below the nominal jaw height.

11. A jaw for use in an endoscopic device comprising:

a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between said side walls, wherein end wall has a sinusoidal tooth profile.

12. A jaw as set forth in claim 11 wherein the side walls have saw tooth profiles.

13. A jaw as set forth in claim 11 wherein said second tooth profile has a spacing different from that of said first tooth profile.

14. A jaw as set forth in claim 13 wherein the spacing of said second tooth profile is longer than that of said first tooth profile.

15. A jaw as set forth in claim 13 wherein the spacing of said first tooth profile has a generally uniform spacing.

16. An endoscopic device comprising:

an elongate member having opposite ends;

a pair of jaws mounted for pivotal movement on one end of said opposite ends, each jaw including a cup having opposite side walls extending longitudinally along the jaw, and an end wall extending between said side walls, wherein the opposite side walls have a first tooth profile and the end wall has a second tooth profile different from the first tooth profile; and

an actuator member operatively connected to said pair of jaws for moving the jaws between a closed position in which the end of the corresponding jaw is positioned adjacent said other jaw and an open position in which an end of the jaw is spaced from the other jaw.

17. A device as set forth in claim 16 wherein said second tooth profile has a shape different from that of said first tooth profile.

18. A device as set forth in claim 16 wherein said second tooth profile comprises a sinusoidal shape.

19. A device as set forth in claim 16 wherein said second tooth profile has a spacing different from that of said first tooth profile.

20. A device as set forth in claim 19 wherein the spacing of said second tooth profile is shorter than that of said first tooth profile.
