METHOD AND SYSTEMS FOR OPERATING A WIND TURBINE WHEN RECOVERING FROM A GRID CONTINGENCY EVENT

ABSTRACT

A method for controlling operation of a wind turbine included within a power generation and delivery system is described. The method includes receiving, by a controller, a power command signal, wherein the power command signal indicates recovery from the grid contingency event; and increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response to the power command signal wherein the controller controls the power conversion assembly.

METHOD AND SYSTEMS FOR OPERATING A WIND TURBINE WHEN RECOVERING FROM A GRID CONTINGENCY EVENT

BACKGROUND OF THE INVENTION

[0001] The subject matter described herein relates generally to controlling operation of a wind turbine, and more specifically, to controlling operation of a wind turbine in response to a power grid contingency event.

[0002] Wind turbine generators utilize wind energy to produce electrical power. Wind turbine generators typically include a rotor having multiple blades that transform wind energy into rotational motion of a drive shaft, which in turn is utilized to drive an electrical generator to produce electrical power. Each of the multiple blades may be pitched to increase or decrease the rotational speed of the rotor. A power output of a wind turbine generator increases with wind speed until the wind speed reaches a rated wind speed for the turbine. At and above the rated wind speed, the wind turbine generator operates at a rated power. The rated power is an output power at which a wind turbine generator can operate with a level of fatigue to turbine components that is predetermined to be acceptable. At wind speeds higher than a certain speed, or at a wind turbulence level that exceeds a predetermined magnitude, typically referred to as a “trip limit” or “monitor set point limit,” wind turbines may be shut down, or the loads may be reduced by regulating the pitch of the blades or braking the rotor, in order to protect wind turbine components against damage.

[0003] Variable speed operation of the wind turbine generator facilitates enhanced capture of energy by the wind turbine generator when compared to a constant speed operation of the wind turbine generator, however, variable speed operation of the wind turbine generator produces electricity having varying voltage and/or frequency. More specifically, the frequency of the electricity generated by the variable speed wind turbine generator is proportional to the speed of rotation of the rotor. A power converter

260916

may be coupled between the electric generator and a utility grid. The power converter outputs electricity having a fixed voltage and frequency for delivery on the utility grid.

[0004] A balance between a torque on the rotor created by interaction of the rotor blades and the wind and a generator torque facilitates stable operation of the wind turbine. Wind turbine adjustments, for example, blade pitch adjustments, or grid events, for example, low voltages or zero voltages on the grid, may cause an imbalance between the torque on the rotor caused by the wind and the generator torque. The electric generator has an air gap torque between the generator rotor and stator that opposes the torque applied by the rotor. The power converter also controls the air gap torque which facilitates controlling the power output of the electric generator. However, the wind turbine may not be able to operate through certain grid events, or may sustain wear and/or damage due to certain grid events, due to a time period required for adjustments to wind turbine operation to take effect after detecting the grid event. Furthermore, when controlling the power output after a grid event, rotor vibration and overspeed can become an issue depending upon the rate at which power output is restored.

[0005] Therefore, what are desired are methods and systems that overcome challenges in the art, some of which are described above.

BRIEF DESCRIPTION OF THE INVENTION

[0006] In one aspect, a method for controlling operation of a wind turbine included within a power generation and delivery system, the wind turbine comprising a rotor comprising a plurality of rotor blades, an electrical generator, a power converter, and a controller, is provided. The method includes measuring at least one operating condition of the power generation and delivery system; transmitting, to a power limiter system, an operating condition feedback signal that corresponds to the operating condition; analyzing, using the power limiter system, the operating condition feedback signal to identify an occurrence of a grid contingency event; generating, using the power limiter system, a power command signal corresponding to the occurrence of the grid contingency event; transmitting the power command signal to the controller; and,

260916

controlling operation of the power converter based at least in part on the power command signal by increasing real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event.

[0007] In another aspect, a method of recovering from a grid contingency event is provided. The method includes receiving, by a controller, a power command signal, wherein the power command signal indicates recovery from the grid contingency event. The method further comprises increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response to the power command signal, wherein the controller controls the power conversion assembly.

[0008] In another aspect, a power generation and distribution system is provided. The power generation and distribution system includes an electric generator and a power conversion assembly coupled to the electric generator and a utility grid. The power conversion assembly is configured to receive power generated by the electric generator and convert the power received to a power suitable for transmission over the utility grid. The power conversion assembly is further configured to increase a real current output by the power conversion assembly in a non-uniform manner upon receipt of a real current control signal corresponding to recovery from a grid contingency event. The power generation and distribution system also includes a power limiter system communicatively coupled to the power conversion assembly and configured to provide a real current control signal to the power conversion assembly. The real current control signal based at least partially on at least one measured indicator of a grid contingency event. The power limiter system includes a memory configured to store at least one variable that corresponds to the occurrence of the grid contingency event.

[0009] Additional advantages will be set forth in part in the description which follows or may be learned by practice. The advantages will be realized and attained by means of the elements and combinations particularly pointed out in the appended claims. It is to be understood that both the foregoing general description and

260916

the following detailed description are exemplary and explanatory only and are not restrictive, as claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] Figure 1 is a perspective view of a portion of an exemplary wind turbine.

[0011] Figure 2 is a partially cut-away view of a portion of the wind turbine shown in Figure 1.

[0012] Figure 3 is a block diagram of the wind turbine shown in Figure 1.

[0013] Figure 4 is a block diagram of an exemplary power generation and delivery system that may include the wind turbine shown in Figure 1.

[0014] Figure 5 is a block diagram of an exemplary power limiter system that may be included within the power generation and delivery system shown in Figure 4.

[0015] Figure 6 is a block diagram of an exemplary grid-dependent power limiter that may be included within the power limiter system shown in Figure 5.

[0016] Figures 7A and 7B are non-limiting examples of graphical representations of non-uniform ramp rates for power injection into the grid during recovery from a grid contingency event.

[0017] Figure 8 is a graphical view of a grid line voltage versus time that may be associated with the wind turbine shown in Figure 1.

[0018] Figure 9 illustrates a simulation of power output from a wind turbine included within a power generation and delivery system upon recovery from a

260916

grid contingency event comparing uniform rate of recovery (dashed line) with non-uniform rate of recovery (solid line).

[0019] Figure 10 illustrates a simulation of generator speed of a wind turbine included within a power generation and delivery system upon recovery from a grid contingency event comparing uniform rate of recovery (dashed line) 1002 with a non-uniform rate of recovery (solid line) 1004.

[0020] Figure 11 is a flow chart showing an exemplary method of controlling operation of the wind turbine shown in Figure 1.

DETAILED DESCRIPTION OF THE INVENTION

[0021] Before the present methods and systems are disclosed and described, it is to be understood that the methods and systems are not limited to specific synthetic methods, specific components, or to particular compositions. It is also to be understood that the terminology used herein is for describing particular embodiments only and is not intended to be limiting.

[0022] As used in the specification and the appended claims, the singular forms “a,” “an” and “the” include plural referents unless the context clearly dictates otherwise. Ranges may be expressed herein as from “about” one particular value, and/or to “about” another particular value. When such a range is expressed, another embodiment includes from the one particular value and/or to the other particular value. Similarly, when values are expressed as approximations, by use of the antecedent “about,” it will be understood that the particular value forms another embodiment. It will be further understood that the endpoints of each of the ranges are significant both in relation to the other endpoint, and independently of the other endpoint.

[0023] “Optional” or “optionally” means that the subsequently described event or circumstance may or may not occur, and that the description includes instances where said event or circumstance occurs and instances where it does not.

260916

[0024] Throughout the description and claims of this specification, the word “comprise” and variations of the word, such as “comprising” and “comprises,” means “including but not limited to,” and is not intended to exclude, for example, other additives, components, integers or steps. “Exemplary” means “an example of” and is not intended to convey an indication of a preferred or ideal embodiment. “Such as” is not used in a restrictive sense, but for explanatory purposes.

[0025] As used herein, the term “blade” is intended to be representative of any device that provides reactive force when in motion relative to a surrounding fluid. As used herein, the term “wind turbine” is intended to be representative of any device that generates rotational energy from wind energy, and more specifically, converts kinetic energy of wind into mechanical energy. As used herein, the term “wind turbine generator” is intended to be representative of any wind turbine that generates electrical power from rotational energy generated from wind energy, and more specifically, converts mechanical energy converted from kinetic energy of wind to electrical power.

[0026] Disclosed are components that can be used to perform the disclosed methods and systems. These and other components are disclosed herein, and it is understood that when combinations, subsets, interactions, groups, etc. of these components are disclosed that while specific reference of each various individual and collective combinations and permutation of these may not be explicitly disclosed, each is specifically contemplated and described herein, for all methods and systems. This applies to all aspects of this application including, but not limited to, steps in disclosed methods. Thus, if there are a variety of additional steps that can be performed it is understood that each of these additional steps can be performed with any specific embodiment or combination of embodiments of the disclosed methods.

[0027] The present methods and systems may be understood more readily by reference to the following detailed description of preferred embodiments and the examples included therein and to the Figures and their previous and following description.

[0028] Technical effects of the methods, systems, and computer-readable media described herein include at least one of: (a) measuring a terminal grid voltage; (b) providing, to a power limiter system, a terminal grid voltage feedback signal that corresponds to the terminal grid voltage; (c) generating, using the power limiter system, a real current command signal based at least partially on the terminal grid voltage feedback signal; (d) providing the real current command signal to the controller; and (e) applying the real current command signal to power converter performance such that real current output by the power converter increases in a non-uniform manner upon receipt of a real current control signal corresponding to recovery from a grid contingency event.

[0029] The methods, systems, and computer readable media described herein facilitate identification of a grid contingency event and a rapid response to the grid contingency event. The rapid response can reduce or substantially eliminate pole-slipping in the wind turbine generator and facilitate stabilizing the wind turbine and utility grid. The non-uniform rate of power output return after a grid contingency event can reduce or eliminate rotor vibration and overspeed and/or power overshoot.

[0030] Figure 1 is a perspective view of an exemplary wind turbine 10. Figure 2 is a partially cut-away perspective view of a portion of wind turbine 10. Wind turbine 10 described and shown herein is a wind turbine generator for generating electrical power from wind energy. Moreover, wind turbine 10 described and illustrated herein includes a horizontal-axis configuration, however, in some embodiments, wind turbine 10 may include, in addition or alternative to the horizontal-axis configuration, a vertical-axis configuration (not shown). Wind turbine 10 may be coupled to an electrical load (not shown in Figure 1), such as, but not limited to, a power grid, for receiving electrical power therefrom to drive operation of wind turbine 10 and/or its associated components and/or for supplying electrical power generated by wind turbine 10 thereto. Although only one wind turbine 10 is shown in Figures 1 and 2, in some embodiments, a plurality of wind turbines 10 may be grouped together, sometimes referred to as a "wind farm."

260916

[0031] Wind turbine 10 includes a body or nacelle 12 and a rotor (generally designated by 14) coupled to nacelle 12 for rotation with respect to nacelle 12 about an axis of rotation 20. In the exemplary embodiment, nacelle 12 is mounted on a tower 16, however, in some embodiments, in addition or alternative to tower-mounted nacelle 12, nacelle 12 may be positioned adjacent the ground and/or a surface of water. The height of tower 16 may be any suitable height enabling wind turbine 10 to function as described herein. Rotor 14 includes a hub 22 and a plurality of blades 24 (sometimes referred to as "airfoils") extending radially outwardly from hub 22 for converting wind energy into rotational energy. Although rotor 14 is described and illustrated herein as having three blades 24, rotor 14 may have any number of blades 24. Blades 24 may each have any length that allows wind turbine 10 to function as described herein. For example, in some embodiments, one or more rotor blades 24 are about one-half meter long, while in some embodiments one or more rotor blades 24 are about fifty meters long. Other examples of blade 24 lengths include ten meters or less, about twenty meters, about thirty-seven meters, and about forty meters. Still other examples include rotor blades between about fifty and about one-hundred meters long, and rotor blades greater than one-hundred meters long.

[0032] Despite how rotor blades 24 are illustrated in Figure 1, rotor 14 may have blades 24 of any shape, and may have blades 24 of any type and/or any configuration, whether such shape, type, and/or configuration is described and/or illustrated herein. One example of another type, shape, and/or configuration of blades 24 is a Darrieus wind turbine, sometimes referred to as an "eggbeater" turbine. Yet another example of another type, shape, and/or configuration of blades 24 is a Savonius wind turbine. Moreover, wind turbine 10 may, in some embodiments, be a wind turbine wherein rotor 14 generally faces upwind to harness wind energy, and/or may be a wind turbine wherein rotor 14 generally faces downwind to harness energy. Of course, in any of the embodiments, rotor 14 may not face exactly upwind and/or downwind, but may face generally at any angle (which may be variable) with respect to a direction of the wind to harness energy therefrom.

[0033] Referring now to Figure 2, wind turbine 10 includes an electrical generator 26 coupled to rotor 14 for generating electrical power from the rotational energy generated by rotor 14. Generator 26 may be any suitable type of electrical generator, such as, but not limited to, a wound rotor induction generator, a double-fed induction generator (DFIG, also known as dual-fed asynchronous generators), a permanent magnet (PM) synchronous generator, an electrically-excited synchronous generator, and a switched reluctance generator. Generator 26 includes a stator (not shown) and a rotor (not shown) with an air gap included therebetween. Rotor 14 includes a rotor shaft 28 coupled to rotor hub 22 for rotation therewith. Generator 26 is coupled to rotor shaft 28 such that rotation of rotor shaft 28 drives rotation of the generator rotor, and therefore operation of generator 26. In the exemplary embodiment, the generator rotor has a generator shaft 30 coupled thereto and coupled to rotor shaft 28 such that rotation of rotor shaft 28 drives rotation of the generator rotor. In other embodiments, the generator rotor is directly coupled to rotor shaft 28, sometimes referred to as a "direct-drive wind turbine." In the exemplary embodiment, generator shaft 30 is coupled to rotor shaft 28 through a gearbox 32, although in other embodiments generator shaft 30 is coupled directly to rotor shaft 28.

[0034] The torque of rotor 14 drives the generator rotor to thereby generate variable frequency AC electrical power from rotation of rotor 14. Generator 26 has an air gap torque between the generator rotor and stator that opposes the torque of rotor 14. A power conversion assembly 34 is coupled to generator 26 for converting the variable frequency AC to a fixed frequency AC for delivery to an electrical load (not shown in Figure 2), such as, but not limited to a power grid (not shown in Figure 2), coupled to generator 26. Power conversion assembly 34 may include a single frequency converter or a plurality of frequency converters configured to convert electricity generated by generator 26 to electricity suitable for delivery over the power grid. Power conversion assembly 34 may also be referred to herein as a power converter. Power conversion assembly 34 may be located anywhere within or remote to wind turbine 10.

260916

For example, power conversion assembly 34 may be located within a base (not shown) of tower 16.

[0035] In some embodiments, wind turbine 10 may include a rotor speed limiter, for example, but not limited to a disk brake 36. Disk brake 36 brakes rotation of rotor 14 to, for example, slow rotation of rotor 14, brake rotor 14 against full wind torque, and/or reduce the generation of electrical power from electrical generator 26. Furthermore, in some embodiments, wind turbine 10 may include a yaw system 38 for rotating nacelle 12 about an axis of rotation 40 for changing a yaw of rotor 14, and more specifically for changing a direction faced by rotor 14 to, for example, adjust an angle between the direction faced by rotor 14 and a direction of wind.

[0036] In one embodiment, wind turbine 10 includes a variable blade pitch system 42 for controlling, including but not limited to changing, a pitch angle of blades 24 (shown in Figures 1-2) with respect to a wind direction. Pitch system 42 may be coupled to system controller 44 for control thereby. Pitch system 42 is coupled to hub 22 and blades 24 for changing the pitch angle of blades 24 by rotating blades 24 with respect to hub 22. The pitch actuators may include any suitable structure, configuration, arrangement, means, and/or components, whether described and/or shown herein, such as, but not limited to, electrical motors, hydraulic cylinders, springs, and/or servomechanisms. Moreover, the pitch actuators may be driven by any suitable means, whether described and/or shown herein, such as, but not limited to, hydraulic fluid, electrical power, electro-chemical power, and/or mechanical power, such as, but not limited to, spring force.

[0037] Figure 3 is a block diagram of an exemplary embodiment of wind turbine 10. In the exemplary embodiment, wind turbine 10 includes one or more system controllers 44 coupled to at least one component of wind turbine 10 for generally controlling operation of wind turbine 10 and/or controlling operation of the components thereof, regardless of whether such components are described and/or shown herein. For example, in the exemplary embodiment system controller 44 is coupled to pitch system

42 for generally controlling rotor 14. In the exemplary embodiment, system controller 44 is mounted within nacelle 12 (shown in Figure 2), however, additionally or alternatively, one or more system controllers 44 may be remote from nacelle 12 and/or other components of wind turbine 10. System controllers 44 may be used for overall system monitoring and control including, without limitation, pitch and speed regulation, high-speed shaft and yaw brake application, yaw and pump motor application, and/or fault monitoring. Alternative distributed or centralized control architectures may be used in some embodiments.

[0038] In an exemplary embodiment, wind turbine 10 includes a plurality of sensors, for example, sensors 50, 54, and 56. Sensors 50, 54, and 56 measure a variety of parameters including, without limitation, operating conditions and atmospheric conditions. Each sensor 50, 54, and 56 may be an individual sensor or may include a plurality of sensors. Sensors 50, 54, and 56 may be any suitable sensor having any suitable location within or remote to wind turbine 10 that allows wind turbine 10 to function as described herein. In some embodiments, sensors 50, 54, and 56 are coupled to system controller 44 for transmitting measurements to system controller 44 for processing thereof.

[0039] In some embodiments, system controller 44 includes a bus 62 or other communications device to communicate information. One or more processor(s) 64 are coupled to bus 62 to process information, including information from sensors 50, 54, and 56 and/or other sensor(s). Processor(s) 64 may include at least one computer. As used herein, the term computer is not limited to integrated circuits referred to in the art as a computer, but broadly refers to a processor, a microcontroller, a microcomputer, a programmable logic controller (PLC), an application specific integrated circuit, and other programmable circuits, and these terms are used interchangeably herein.

[0040] System controller 44 may also include one or more random access memories (RAM) 66 and/or other storage device(s) 68. RAM(s) 66 and storage device(s) 68 are coupled to bus 62 to store and transfer information and instructions to be

260916

executed by processor(s) 64. RAM(s) 66 (and/or storage device(s) 68, if included) can also be used to store temporary variables or other intermediate information during execution of instructions by processor(s) 64. System controller 44 may also include one or more read only memories (ROM) 70 and/or other static storage devices coupled to bus 62 to store and provide static (i.e., non-changing) information and instructions to processor(s) 64. Processor(s) 64 process information transmitted from a plurality of electrical and electronic devices that may include, without limitation, speed and power transducers. Instructions that are executed include, without limitation, resident conversion and/or comparator algorithms. The execution of sequences of instructions is not limited to any specific combination of hardware circuitry and software instructions.

[0041] System controller 44 may also include, or may be coupled to, input/output device(s) 72. Input/output device(s) 72 may include any device known in the art to provide input data to system controller 44 and/or to provide outputs, such as, but not limited to, yaw control and/or pitch control outputs. Instructions may be provided to RAM 66 from storage device 68 including, for example, a magnetic disk, a read-only memory (ROM) integrated circuit, CD-ROM, and/or DVD, via a remote connection that is either wired or wireless providing access to one or more electronically-accessible media. In some embodiments, hard-wired circuitry can be used in place of or in combination with software instructions. Thus, execution of sequences of instructions is not limited to any specific combination of hardware circuitry and software instructions, whether described and/or shown herein. Also, in the exemplary embodiment, input/output device(s) 72 may include, without limitation, computer peripherals associated with an operator interface such as a mouse and a keyboard (neither shown in Figure 3). Alternatively, other computer peripherals may also be used that may include, for example, a scanner (not shown in Figure 3). Furthermore, in the exemplary embodiment, additional output channels may include, for example, an operator interface monitor (not shown in Figure 3). System controller 44 may also include a sensor interface 74 that allows system controller 44 to communicate with sensors 50, 54, and 56 and/or other sensor(s). Sensor interface 74 may include one or more analog-to-digital

260916

converters that convert analog signals into digital signals that can be used by processor(s) 64.

[0042] In an exemplary embodiment, wind turbine 10 includes a phase locked loop (PLL) regulator 80. PLL regulator 80 is coupled to sensor 54. In the exemplary embodiment, sensor 54 is a voltage transducer configured to measure a terminal grid voltage output by frequency converter 34. Alternatively, PLL regulator 80 is configured to receive a plurality of voltage measurement signals from a plurality of voltage transducers. In an example of a three-phase generator, each of three voltage transducers is electrically coupled to each one of three phases of a grid bus. PLL regulator 80 may be configured to receive any number of voltage measurement signals from any number of voltage transducers that allow PLL regulator 80 to function as described herein.

[0043] Figure 4 is a block diagram of an exemplary power generation and delivery system 150. Power generation and delivery system 150 may be used with, or included within, wind turbine 10 (shown in Figures 1 and 2). System 150 includes an energy source, for example, generator 26. Although described herein as wind turbine generator 26, the energy source may include any type of electrical generator that allows system 150 to function as described herein. System 150 also includes a power converter, such as, power converter 34. Power converter 34 receives variable frequency electrical power 132 generated by generator 26 and converts electrical power 132 to an electrical power 134 (referred to herein as terminal power 134) suitable for transmission over an electric power transmission and distribution grid 136 (referred to herein as utility grid 136). A terminal voltage (V_t) 138 is defined at a node between power converter 34 and utility grid 136. A load 140 is coupled to utility grid 136 where a Thevenin voltage is defined. As described above, variable speed operation of wind turbine 10 facilitates enhanced capture of energy when compared to a constant speed operation of wind turbine 10, however, variable speed operation of wind turbine 10 produces electrical power 132 having varying voltage and/or frequency. More specifically, the frequency of electrical power 132 generated by variable speed wind turbine generator 26 is proportional to the

260916

speed of rotation of rotor 14 (shown in Figure 1). In the exemplary embodiment, power converter 34 outputs terminal power 134 having a substantially fixed voltage and frequency for delivery on utility grid 136.

[0044] Power converter 34 also controls an air gap torque of generator 26. The air gap torque is present between the generator rotor (not shown in Figure 3) and the generator stator (not shown in Figure 3) and opposes the torque applied to generator 26 by rotor 14. A balance between a torque on rotor 14 created by interaction of blades 24 (shown in Figure 1) and the wind and the air gap torque facilitates stable operation of wind turbine 10. Wind turbine adjustments, for example, blade pitch adjustments, or grid events, for example, low voltage transients or zero voltage transients on utility grid 136, may cause an imbalance between the torque on rotor 14 caused by the wind and the air gap torque. Power converter 34 controls the air gap torque which facilitates controlling the power output of generator 26, however, wind turbine 10 may not be able to operate through certain grid events, or may sustain wear and/or damage due to certain grid events, due to a time period required for adjustments to wind turbine operation to take effect after detecting the grid event.

[0045] In the exemplary embodiment, system 150 includes a grid-dependent power limiter system 152. In the exemplary embodiment, a controller, for example, but not limited to, controller 44 (shown in Figure 3), is programmed to perform the functions of grid-dependent power limiter system 152. However, in alternative embodiments, the functions of grid-dependent power limiter system 152 may be performed by any circuitry configured to allow system 150 to function as described herein. Power limiter system 152 is configured to identify the occurrence of a grid contingency event, and provide power converter 34 with signals that facilitate reducing pole-slipping and providing a stable recovery from the grid event. In certain embodiments, power converter 34 responds according to the signals provided by power limiter system 152 and substantially eliminates pole-slipping.

260916

[0046] A grid event, also referred to herein as a grid contingency event, may leave utility grid 136 in a degraded mode where the grid impedance is too high to accommodate power generated by generator 26. An example of a grid event includes a short-circuit fault on one of the transmission lines within utility grid 136. Electrical transmission protection actions remove the faulted portion of utility grid 136 to permit operation of the remaining unfaulted portion of utility grid 136. A transmission path remains that is degraded in its ability to transmit power from system 150 to load 140. Such grid events cause a brief period of low voltage on utility grid 136 prior to clearing the faulted portion of the utility grid 136. Typically, terminal voltage 138 will approach zero volts at the time of the grid event. Often, a low voltage transient and/or a zero voltage transient will cause a generator trip and associated consequences to the semiconductor devices (e.g., potential damage to components of wind turbine 10). System 150 facilitates low voltage ride through capability (LVRT) as well as zero voltage ride through (ZVRT) capability for wind turbine 10 such that a potential for a wind turbine generator trip and associated consequences to the semiconductor devices are mitigated during low voltage transients and/or zero voltage transients.

[0047] Such a grid event may lead to a post-fault condition where the high impedance of utility grid 136 prevents utility grid 136 from transmitting the pre-fault power from wind generator 26 (i.e., the impedance of utility grid 136 is too high to carry the pre-fault power from wind generator 26). In a synchronous machine, this condition may cause a rotor angle of the generator rotor to move past the point where a restraining torque of utility grid 136 is able to balance the mechanical input to wind turbine 10, which is referred to herein as “pole-slipping.” In a machine with a power electronic interface (e.g., power converter 34), this condition may lead to a series of rapid pulsations of power and voltage. Such pulsations are analogous to pole-slipping, although with power converter 34, control algorithms govern the behavior rather than the physics of synchronous machines. Without precautions in the power converter control algorithms, pole-slipping may occur.

[0048] The methods and systems described herein facilitate preventing the pulsating pole-slipping and facilitate stabilizing system 150 upon detection of pole-slipping in a short period of time such that higher-level controls have time to determine actions and communicate those actions to bring the system to an acceptable condition.

[0049] As shown in Figure 4, in the exemplary embodiment, power conversion assembly 34 is configured to receive control signals 154 from a converter interface controller 156. Control signals 154 are based on sensed operating conditions or operating characteristics of wind turbine 10 as described herein and used to control the operation of power conversion assembly 34. Examples of measured operating conditions may include, but are not limited to, a terminal grid voltage, a PLL error, a stator bus voltage, a rotor bus voltage, and/or a current. For example, sensor 54 measures terminal grid voltage 138 and transmits a terminal grid voltage feedback signal 160 to power limiter system 152. Power limiter system 152 generates a power command signal 162 based at least partially on the feedback signal 160 and transmits power command signal 162 to converter interface controller 156. In an alternative embodiment, converter interface controller 156 is included within system controller 44. Other operating condition feedback from other sensors also may be used by controller 44 and/or converter interface controller 156 to control power conversion assembly 34. Using this feedback information, and for example, switching control signals, stator synchronizing switch control signals and system circuit breaker control (trip) signals may be generated in any known manner. For example, for a grid voltage transient with predetermined characteristics, controller 44 and/or converter interface controller 156 will at least temporarily substantially suspend firing of the IGBTs within power conversion assembly 34. Such suspension of operation will substantially mitigate electric power being channeled through power conversion assembly 34 to approximately zero.

[0050] Figure 5 is a block diagram of an exemplary power limiter system, for example, power limiter system 152. Power limiter system 152 is configured to output power command signal 162 (shown in Figure 4), which in the exemplary embodiment, is at least one of a real current command signal 166 and a reactive current

command signal 168. In the exemplary embodiment, power limiter system 152 includes a power limiter 180, a power regulator 182, and a voltage regulator 184. In the exemplary embodiment, power limiter 180 receives at least one measured operating condition of system 150. The at least one measured operating condition may include, but is not limited to, a PLL error signal 190 from PLL regulator 80 and terminal grid voltage feedback signal 160 from sensor 54. Power limiter 180 also receives a stored reference power control signal 194 from, for example, system controller 44 (shown in Figure 3). In some embodiments, power limiter 180 receives terminal grid voltage feedback signal 160 and stored reference power control signal 194. In other embodiments, power limiter 180 receives PLL error signal 190 and stored reference power control signal 194. In other embodiments, power limiter 180 receives both PLL error signal 190 and terminal grid voltage feedback signal 160, as well as stored reference power control signal 194. In the exemplary embodiment, power limiter 180 generates a power command signal 198 and transmits power command signal 198 to power regulator 182. Power regulator 182 generates real current command signal 166 and transmits real current command signal 166 to converter interface controller 156. Converter interface controller 156 may also be referred to herein as a converter firing control. As described above, PLL regulator 80 may be included within system controller 44, or may be coupled to, but separate from, system controller 44.

[0051] In the exemplary embodiment, PLL regulator 80 receives terminal voltage feedback signal 160. For example, PLL regulator 80 may receive terminal voltage feedback signal 160 (shown in Figure 3 as V_t) provided by sensor 54 (shown in Figure 3). As described above, PLL regulator 80 generates PLL error signal 190 and a PLL phase angle signal 202. PLL phase angle signal 202 is transmitted to converter interface controller 156 for control of assembly 34 and for subsequent control of electrical currents injected onto utility grid 136 (shown in Figure 4).

[0052] Figure 6 is a block diagram of an exemplary grid-dependent power limiter, for example, power limiter 180 (shown in Figure 5). As described above, in the event of a grid contingency such as a weak grid, the impedance of utility grid 136

is too high to accommodate the power generated by generator 26. As a result, pole-slipping may occur causing repetitive voltage depressions and power pulsations on utility grid 136 and wind turbine 10. Also, the weak grid causes a reduction in the Thevenin equivalent voltage at load 140 on utility grid 136. To facilitate preventing pole-slipping from occurring after a grid contingency event, a power command to converter interface controller 156 is rapidly reduced. More specifically, real current command signal 166 is generated by power regulator 182 and transmitted to converter interface controller 156. Real current command signal 166 instructs converter interface controller 156 to decrease a real component of current that conversion assembly 34 tries to inject onto utility grid 136. Furthermore, to support the terminal voltage, upon a drop in terminal voltage identified by voltage regulator 184 based on terminal voltage feedback signal 160, voltage regulator 184 generates reactive current command signal 168 and sends reactive current command signal 168 to converter interface controller 156. Current command signal 168 instructs converter interface controller 156 to increase a reactive component of current injected onto utility grid 136 upon occurrence of a grid contingency event.

[0053] In the exemplary embodiment, power regulator 182 receives power command signal 198 from power limiter 180. Power command signal 198 provides power regulator 182 with a signal corresponding to an occurrence of a grid contingency event. As described above, a low terminal voltage is an indication that a grid contingency event has occurred. Also, a high PLL error is an indication that a grid contingency event has occurred. To determine if a grid contingency event has occurred, a function block 220 within power limiter 180 receives terminal voltage feedback signal 160 and/or PLL error signal 190. A power limit function block 222 generates a power limit control signal 224 based on an output 226 of function block 220. Power limit control signal 224 and reference power control signal 194 are provided to a comparator function block 230. Comparator function block 230 generates power command signal 198 corresponding to the lesser of power limit control signal 224 and reference power control signal 194.

[0054] In the exemplary embodiment, upon occurrence of a grid contingency event, terminal voltage feedback signal 160 indicates a sudden reduction in the terminal voltage. Accordingly, power limit function block 222 generates a rapidly reducing power limit control signal 224. Rapidly reducing power limit control signal 224 facilitates stabilizing system 150 while substantially reducing pole-slipping. After terminal voltage feedback signal 160 indicates that the grid contingency event has ended (e.g., the terminal voltage increases), power limit function block 222 generates a non-uniform power limit control signal 224. The real current injected onto utility grid 136 rises according to power limit control signal 224. Increasing the power injected onto utility grid 136 in a non-uniform manner facilitates preventing power oscillations, rotor vibration, rotor overspeed, and power overshoot. As used herein, increasing power injected into the grid 136 in a non-uniform manner generally means changing the rate at which power is injected into the grid over time. For example, the rate may start out at a fast rate and then change to a slower rate as the power injected into the grid approaches the power designated by the power limit control signal 224. By changing the power limit control signal 224 over time in a non-uniform manner, power injected into the grid 136 has a fast rise portion up to a safe level for grid stability and then a slow rise portion as full power is approached. For example, the safe level for grid stability may be a first predetermined level of power output. In one non-limiting example, the safe level for grid stability may be from 50 to 70 percent of full power at given conditions. The fast rise portion of power injection in the early part of recovery from a grid contingency event helps reduce rotor overspeed and vibration. Slowly increasing the power injected onto utility grid 136 in the latter portion of power injection into the grid upon recovery provides time for higher level changes in the operation of system 150 that allow system 150 to adapt to the grid contingency event, mitigate overshoot, and reduce what vibration that does occur while achieving full power injected into the grid. In one aspect, the fast rise portion of power injection into the grid when recovering from a grid contingency event comprise changing the power limit control signal 224, and subsequently the power injected into the grid by a ramp rate of 300 percent of rated power at a given wind speed per second, or greater. In one non-limiting example, power is injected into the grid 136 at

260916

a first (fast) rate of 300 percent of rated power at a given wind speed per second, or greater, and then injected into the grid 136 at a second (slow) rate of less than 300 percent of rated power at a given wind speed per second, for example 100 percent of rated power at a given wind speed per second. In another non-limiting example, power is injected into the grid 136 at a first (fast) rate of 300 percent of rated power at a given wind speed per second, or greater, and then injected into the grid 136 at a second (slow) rate of less than 100 percent of rated power at a given wind speed per second.

[0055] Figures 7A and 7B are non-limiting examples of graphical representations of non-uniform ramp rates for power injection into the grid during recovery from a grid contingency event. Figure 7A illustrates a graph 702 having a plurality of linear segments, each segment having a different slope such that rate of bringing the wind turbine back to rated power at a given wind speed is initially fast and then slows as full rated power is approached. Figure 7B illustrates a portion of the ramp rate is non-linear in a graph 704 such that rate of bringing the wind turbine back to rated power at a given wind speed is initially fast and then slows as full rated power is approached. It is to be appreciated that Figures 7A and 7B are examples and any combination of linear or non-linear segments representing the ramp rate can be used for increasing power and/or real current output by the power converter in a non-uniform manner.

[0056] Returning to Figure 6, in the exemplary embodiment, power limit control signal 224 is compared to reference power control signal 194. Comparator function block 230 generates power command signal 198 based on the lower of power limit control signal 224 and reference power control signal 194. For example, power limit control signal 224 is lower than reference power control signal 194 after occurrence of a grid contingency event, and as such, power command signal 198 is generated based on power limit control signal 224. During normal operation of system 150 (i.e., no grid contingency event), reference power control signal 194 is less than power limit control signal 224, and power command signal 198 is based on the predetermined reference power control signal 194.

[0057] As described above, PLL error signal 190 and terminal voltage feedback signal 160 are both indicators of the occurrence of a grid contingency event. For example, a PLL error signal 190 that corresponds to a high PLL error and a terminal voltage feedback signal 160 that corresponds to a reduction in terminal voltage 138 are indications that a grid contingency event has occurred. In response to a high PLL error signal 190 and/or a low terminal voltage feedback signal 160, power limit function block 222 generates a rapidly reducing power limit control signal 224. After PLL error signal 190 and/or terminal voltage feedback signal 160 indicate that the grid contingency event has ended (e.g., the PLL error and/or the terminal voltage returns to a predefined level), power limit function block 222 generates a non-uniform rising power limit control signal 224. The power injected onto utility grid 136 rises in a non-uniform manner according to power limit control signal 224. As described above, the fast rise portion of non-uniform power injection in the early part of recovery from a grid contingency event helps reduce rotor overspeed and vibration. Slowly increasing the power injected onto utility grid 136 in the latter portion of non-uniform power injection into the grid upon recovery provides time for higher level changes in the operation of system 150 that allows system 150 to adapt to the grid contingency event, mitigate overshoot, and reduce what vibration that does occur while achieving full power injected into the grid. In an alternative embodiment, power limiter 180 also includes a higher-level control 232. Although described as included within power limiter 180, higher-level control 232 may also be positioned remotely from power limiter 180. As described above, the fast rise portion of non-uniform power injection in the early part of recovery from a grid contingency event helps reduce rotor overspeed and vibration. Slowly increasing the power injected onto utility grid 136 in the latter portion of non-uniform power injection into the grid upon recovery provides time for higher level changes in the operation of system 150 that allows system 150 to adapt to the grid contingency event, mitigate overshoot, and reduce what vibration that does occur while achieving full power injected into the grid. During the slow portion of increasing the power injected onto utility grid 136, time is provided for higher level changes in the operation of system 150 that allow system 150 to adapt to the grid contingency event. Higher-level control 232 receives at least one wind farm

input signal, for example, input signal 234. Wind farm input signal 234 may correspond to changes in utility grid 136, for example, but not limited to, breaker contact signals or communication signals from remote substations. Input signal 234 may also correspond to a voltage measurement at a point of common coupling for a plurality of wind turbines within a wind farm. In the exemplary embodiment, higher-level control 232 generates a curtailment signal 236 based at least partially on input signal 234, and provides curtailment signal 236 to select wind turbines of the plurality of wind turbines. More specifically, curtailment signal 236 is provided to comparator function block 230, where power command signal 198 is generated. For example, if input signal 234 received by higher-level control 232 corresponds to more than a predefined number of remote substations unable to carry the level of power currently being received, higher-level control 232 will generate curtailment signal 236, which upon receipt, instructs comparator function block 230 to generate a power command signal 198 that curtails a wind turbine's output below that which would otherwise be available from the prevailing wind conditions. In another example, if higher-level control 232 determines that the voltage at the point of common coupling for a plurality of wind turbines has remained below a predefined level for more than a predefined period of time, higher-level control 232 will generate curtailment signal 236, which upon receipt, instructs comparator function block 230 to generate a power command signal 198 that curtails a wind turbine's output below that which would otherwise be available from the prevailing wind conditions.

[0058] In the exemplary embodiment, power limiter system 152 also includes a memory, for example, memory 66 (shown in Figure 3). Memory 66 is configured to store data related to operation of wind turbine 10. For example, memory 66 may store at least one variable that correspond to, for example but not limited to, PLL error 190 and voltage feedback 160. More specifically, controller 44 is configured to sample the current value of predefined variables and store the current value in memory 66 upon occurrence of an event. For example, upon occurrence of a grid contingency event, current values for PLL error 190 and voltage feedback 160 are stored in memory 66.

260916

Memory 66 may be accessed by a user to, for example, monitor operation of wind turbine 10.

[0059] Figure 8 is a graphical view of grid line voltage versus time that may be associated with wind turbine 10 (shown in Figure 1). Graph 240 includes an ordinate (y-axis) 242 that represents grid line voltage in units of percent (%). Y-axis 242 illustrates 0% at the graph origin and extends up to 100%. A grid line voltage of 0% is indicative of zero voltage on utility grid 136 (shown in Figure 4). A grid line voltage of 100% indicates terminal grid voltage 138 is 100% of the nominal pre-determined voltage associated with wind turbine 10. Graph 240 also includes an abscissa (x-axis) 244 that represents time in seconds (s). A zero voltage transient is illustrated to start at time equals zero seconds. This zero voltage transient may correspond to a grid event, for example, a de-coupled load that causes a zero voltage grid condition. In the exemplary embodiment, the zero voltage condition on utility grid 136 is 0.15 seconds wherein the voltage on utility grid 136 fully recovers to 100% at approximately 3.5 seconds after the initiation of the transient. Alternatively, a length of time of the zero voltage condition and the characteristics of a grid voltage recovery depend upon a variety of factors known in the art.

[0060] When the voltage decreases to zero as shown in Figure 8, it is likely that there are faults that prevent generator 26 from transmitting electrical power to utility grid 136. In the event that the wind continues to rotate rotor 14 (shown in Figure 1), generator 26 continues to generate energy that is not converted to electrical energy. Instead, the energy accelerates rotor 14 until a trip feature is initiated that may include a manual trip or an automated overspeed trip.

[0061] Figure 9 illustrates a simulation of power output from a wind turbine included within a power generation and delivery system upon recovery from a grid contingency event comparing uniform rate of recovery (dashed line) 902 with non-uniform rate of recovery (solid line) 904. In this exemplary simulation, rated power output of the wind turbine is approximately 1520 kW. As shown in Figure 9, the wind

260916

turbine experiences a grid contingency event at time = 100 seconds, which dramatically decreases the amount of power injected into the grid. Shortly thereafter, the wind turbine begins recovering power output from the wind turbine that is injected into the grid. Line 902 illustrates an exemplary uniform rate of recovery of approximately 50 percent of rated power per second. As can be seen, this uniform and relatively slow rate of recovery results in a longer time period until rated output power is achieved and considerable overshoot of rated power, thereby causing significant power oscillations until a steady output of rated power is achieved. Furthermore, because of the relatively slow rate of recovery illustrated by line 902 from the grid contingency event, turbine components can be subjected longer to vibrations at various frequencies as the wind turbine recovers from the grid contingency event. These vibrations may cause the wind turbine to trip off-line and/or damage components of the wind turbine. Especially damaging can be long periods where the rotor is moving through the natural frequencies and/or critical speeds of the wind turbine.

[0062] Line 904 illustrates an exemplary non-uniform rate of recovery of rated power after a grid contingency event. As before, shortly after the grid contingency event occurs at approximately 100 seconds, the wind turbine begins to recover by injecting more power into the grid. As shown with line 904, this first involves a fast rise 906 up to a safe level for grid stability, and then a slower rise 908 as a final full rated power and/or real current output is attained. As shown in Figure 9, the fast rise portion 906 of power and/or real current output by the power converter of the wind turbine can comprise a rise of 300 percent per second, or greater. Also, as shown in Figure 9, the slow rise portion 908 of power and/or real current output by the power converter can comprise a rise of less than 300 percent per second. For example, the slow rise portion 908 may comprise a power output recovery rate of approximately 50 percent of rated power output of the wind turbine per second. As can be seen by line 904 in Figure 9, the overshoot of power output using the non-uniform rate of recovery is less severe than when using the slower uniform rate of recovery illustrated by line 902. Furthermore, by

260916

rapidly accelerating through periods of high vibration in the fast rise portion 906, the likelihood of tripping or damage caused by vibration is decreased.

[0063] Figure 10 illustrates a simulation of generator speed of a wind turbine included within a power generation and delivery system upon recovery from a grid contingency event comparing uniform rate of recovery (dashed line) 1002 with a non-uniform rate of recovery (solid line) 1004. In this exemplary simulation, rated generator speed is approximately 1440 revolutions per minute. As shown in Figure 10, the wind turbine experiences a grid contingency event at time = 100 seconds, which dramatically increases generator speed and decreases the amount of power injected into the grid. Shortly thereafter, the wind turbine begins recovering power output from the wind turbine that is injected into the grid. Line 1002 illustrates an exemplary uniform rate of recovery of approximately 50 percent of rated power per second. As can be seen, this uniform and relatively slow rate of recovery results in significantly higher generator speed during and after the grid contingency event. This overspeed may cause the wind turbine to trip off-line and/or damage components of the wind turbine.

[0064] Line 1004 illustrates generator speed after a grid contingency event using an exemplary non-uniform rate of recovery of rated power after the grid contingency event. As before, shortly after the grid contingency event occurs at approximately 100 seconds, the wind turbine begins to recover by injecting more power into the grid. As shown with line 1004, generator speed during and after the contingency event is not as great as it would be using a uniform rate of recovery. This lessens the likelihood of an overspeed trip or damage to the wind turbine.

[0065] Figure 11 is a flow chart 260 illustrating an exemplary method for controlling operation of a wind turbine, for example, wind turbine 10 (shown in Figure 1), included within a power generation and delivery system, for example, power generation and delivery system 150 (shown in Figure 4). Although described as a method for operating a wind turbine, the method may also be applied to operation of more than one wind turbine 10 (i.e., a wind farm). In the exemplary embodiment, the method

260916

includes measuring 270 at least one operating condition of power generation and delivery system 150, wherein the at least one operating condition is dependent upon an occurrence of a grid contingency event. As described above, measured operating conditions provide an indication of an occurrence of a grid contingency event. The measured operating condition may include, but is not limited to, at least one of a phase locked loop (PLL) error and a terminal grid voltage. The method also includes transmitting 272, to a power limiter system, an operating condition feedback signal that corresponds to the at least one operating condition. More specifically, PLL error signal 190 (shown in Figure 5) may be generated by a PLL regulator, for example, PLL regulator 80 (shown in Figure 5) and transmitted 272 to power limiter system 152 (shown in Figure 5). PLL error signal 190 may correspond to a sustained phase error tracked by PLL regulator 80. Also, terminal grid voltage feedback signal 160 (shown in Figure 5) may be measured by sensor 54 (shown in Figure 3) and transmitted 272 to power limiter system 152.

[0066] In the exemplary embodiment, the method also includes analyzing 274, using power limiter system 152, the operating condition feedback signal to identify an occurrence of a grid contingency event. For example, an increasing PLL error signal 190 provides an indication that a grid contingency event is occurring and/or a rapidly decreasing terminal grid voltage 138 provides an indication that a grid contingency event is occurring. The method also includes generating 278, using power limiter system 152, a real current command signal corresponding to an occurrence of a grid contingency event. For example, a real current command signal, such as real current command signal 166 (shown in Figure 5) is generated by power limiter system 152. Real current command signal 166 may be based at least partially on the terminal grid voltage and is used as an indicator of an occurrence of a grid contingency event. For example, a real current command signal 166 is generated that corresponds to an occurrence of a grid contingency event when terminal grid voltage 138 is below a predefined level.

[0067] Real current command signal 166 may also be based at least partially on PLL error signal 190. For example, a real current command signal 166 that

260916

corresponds to an occurrence of a grid contingency event is generated when PLL error signal 190 is above a predefined level.

[0068] Real current command signal 166 may also be based on both terminal grid voltage 138 and PLL error signal 190. In this alternative embodiment, if terminal grid voltage 138 and/or PLL error signal 190 indicate the occurrence of a grid contingency event, power limiter system 152 outputs a real current command signal 166 that corresponds to an occurrence of a grid contingency event.

[0069] The method also includes transmitting 280 real current command signal 166 to a controller, for example, converter interface controller 156 (shown in Figure 5) and applying 282 real current command signal 166 to performance of a power converter, for example, power conversion assembly 34 (shown in Figure 3). Upon receipt of real current command signal 166 that corresponds to an occurrence of a grid contingency event, power conversion assembly 34 rapidly reduces a real current output. Furthermore, upon receipt of a real current command signal 166 that indicates a recovery from the grid contingency event, power conversion assembly 34 increases real current output in a non-uniform manner by power conversion assembly 34 to facilitate a stable recovery from the grid contingency event.

[0070] In the exemplary embodiment, the method also includes storing 284, in a memory, at least one variable corresponding to the at least one operating condition upon the occurrence of a grid contingency event. For example, variables corresponding to the at least one operating condition may be stored 284 in memory 66 (shown in Figure 3). Memory 66 may store a plurality of variables that correspond to, for example but not limited to, PLL error 190 and voltage feedback 160. More specifically, controller 44 is configured to sample the current value of predefined variables and store the current value in memory 66 upon occurrence of an event. For example, upon occurrence of a grid contingency event, current values for PLL error 190 and voltage feedback 160 are stored in memory 66. Memory 66 may be accessed by a user to, for

260916

example, monitor operation of wind turbine 10 and/or verify proper operation of wind turbine 10, power limiter system 152, and/or power generation and delivery system 150.

[0071] The method may also include transmitting 290 terminal grid voltage 138 to a voltage regulator, for example, voltage regulator 184 (shown in Figure 5) and generating 292 a reactive current command signal, for example, reactive current command signal 168, at voltage regulator 184 that increases the reactive current output by power conversion assembly 34 when terminal grid voltage 138 indicates the occurrence of a grid contingency event. The increased reactive current supports terminal grid voltage 138 until the grid contingency event is resolved or higher-level control of wind turbine 10 operation is activated. In some embodiments, a higher-level control, for example, higher-level control 232 (shown in Figure 6), receives a wind farm operating condition, generates a curtailment signal based at least partially on the wind farm operating condition, and transmits the curtailment signal to power limiter system 152.

[0072] The above-described embodiments facilitate efficient and cost-effective operation of a wind turbine. The wind turbine includes a power limiter system that is provided with at least one of a terminal voltage feedback signal and a PLL error signal. The terminal voltage feedback signal and the PLL error signal facilitate identification of a grid contingency event and signals provided by the methods and systems described herein facilitate rapid response to an identified grid contingency event. A rapid reduction in real current applied to the utility grid after identification of a grid contingency event substantially eliminates pole-slipping. A non-uniform increase in real current applied to the utility grid upon recovery of the utility grid provides time for higher-level control systems to balance the power generated by the wind turbine, or by wind turbines within a wind farm, with a load level on the utility grid. The method and systems described herein facilitate achieving zero and low voltage ride through which may prevent a generator trip and/or support the grid during the voltage transient.

[0073] Exemplary embodiments of a wind turbine, power limiter system, and methods for operating a wind turbine in response to an occurrence of a grid

260916

contingency event are described above in detail. The methods, wind turbine, and power limiter system are not limited to the specific embodiments described herein, but rather, components of the wind turbine, components of the power limiter system, and/or steps of the methods may be utilized independently and separately from other components and/or steps described herein. For example, the power limiter system and methods may also be used in combination with other wind turbine power systems and methods, and are not limited to practice with only the power system as described herein. Rather, the exemplary embodiment can be implemented and utilized in connection with many other wind turbine or power system applications.

[0074] Although specific features of various embodiments of the invention may be shown in some drawings and not in others, this is for convenience only. In accordance with the principles of the invention, any feature of a drawing may be referenced and/or claimed in combination with any feature of any other drawing.

[0075] This written description uses examples to disclose the invention, including the best mode, and also to enable any person skilled in the art to practice the invention, including making and using any devices or systems and performing any incorporated methods. The patentable scope of the invention is defined by the claims, and may include other examples that occur to those skilled in the art. Such other examples are intended to be within the scope of the claims if they have structural elements that do not differ from the literal language of the claims, or if they include equivalent structural elements with insubstantial differences from the literal language of the claims.

[0076] As described above and as will be appreciated by one skilled in the art, embodiments of the present invention may be configured as a system, method, or computer program product. Accordingly, embodiments of the present invention may be comprised of various means including entirely of hardware, entirely of software, or any combination of software and hardware. Furthermore, embodiments of the present invention may take the form of a computer program product on a computer-readable

260916

storage medium having computer-readable program instructions (e.g., computer software) embodied in the storage medium. Any suitable non-transitory computer-readable storage medium may be utilized including hard disks, CD-ROMs, optical storage devices, or magnetic storage devices.

[0077] Embodiments of the present invention have been described above with reference to block diagrams and flowchart illustrations of methods, apparatuses (i.e., systems) and computer program products. It will be understood that each block of the block diagrams and flowchart illustrations, and combinations of blocks in the block diagrams and flowchart illustrations, respectively, can be implemented by various means including computer program instructions. These computer program instructions may be loaded onto a general purpose computer, special purpose computer, or other programmable data processing apparatus, such as the one or more processors 64 discussed above with reference to Figure 3, to produce a machine, such that the instructions which execute on the computer or other programmable data processing apparatus create a means for implementing the functions specified in the flowchart block or blocks.

[0078] These computer program instructions may also be stored in a non-transitory computer-readable memory that can direct a computer or other programmable data processing apparatus (e.g., one or more processors 64 of Figure 3) to function in a particular manner, such that the instructions stored in the computer-readable memory produce an article of manufacture including computer-readable instructions for implementing the function specified in the flowchart block or blocks. The computer program instructions may also be loaded onto a computer or other programmable data processing apparatus to cause a series of operational steps to be performed on the computer or other programmable apparatus to produce a computer-implemented process such that the instructions that execute on the computer or other programmable apparatus provide steps for implementing the functions specified in the flowchart block or blocks.

[0079] Accordingly, blocks of the block diagrams and flowchart illustrations support combinations of means for performing the specified functions, combinations of steps for performing the specified functions and program instruction means for performing the specified functions. It will also be understood that each block of the block diagrams and flowchart illustrations, and combinations of blocks in the block diagrams and flowchart illustrations, can be implemented by special purpose hardware-based computer systems that perform the specified functions or steps, or combinations of special purpose hardware and computer instructions.

[0080] Unless otherwise expressly stated, it is in no way intended that any method set forth herein be construed as requiring that its steps be performed in a specific order. Accordingly, where a method claim does not actually recite an order to be followed by its steps or it is not otherwise specifically stated in the claims or descriptions that the steps are to be limited to a specific order, it is no way intended that an order be inferred, in any respect. This holds for any possible non-express basis for interpretation, including: matters of logic with respect to arrangement of steps or operational flow; plain meaning derived from grammatical organization or punctuation; the number or type of embodiments described in the specification.

[0081] Throughout this application, various publications may be referenced. The disclosures of these publications in their entireties are hereby incorporated by reference into this application in order to more fully describe the state of the art to which the methods and systems pertain.

[0082] Many modifications and other embodiments of the inventions set forth herein will come to mind to one skilled in the art to which these embodiments of the invention pertain having the benefit of the teachings presented in the foregoing descriptions and the associated drawings. Therefore, it is to be understood that the embodiments of the invention are not to be limited to the specific embodiments disclosed and that modifications and other embodiments are intended to be included within the scope of the appended claims. Moreover, although the foregoing descriptions and the

260916

associated drawings describe exemplary embodiments in the context of certain exemplary combinations of elements and/or functions, it should be appreciated that different combinations of elements and/or functions may be provided by alternative embodiments without departing from the scope of the appended claims. In this regard, for example, different combinations of elements and/or functions than those explicitly described above are also contemplated as may be set forth in some of the appended claims. Although specific terms are employed herein, they are used in a generic and descriptive sense only and not for purposes of limitation.

260916

WHAT IS CLAIMED IS:

1. A method for controlling operation of a wind turbine included within a power generation and delivery system, the wind turbine comprising a rotor comprising a plurality of rotor blades, an electrical generator, a power converter, and a controller, said method comprising:

measuring at least one operating condition of the power generation and delivery system, the operating condition dependent upon an occurrence of a grid contingency event;

transmitting, to a power limiter system, an operating condition feedback signal that corresponds to the operating condition;

analyzing, using the power limiter system, the operating condition feedback signal to identify an occurrence of a grid contingency event;

generating, using the power limiter system, a power command signal corresponding to the occurrence of the grid contingency event;

transmitting the power command signal to the controller; and

controlling operation of the power converter based at least in part on the power command signal by increasing real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event.

2. A method in accordance with claim 1, further comprising storing, in a memory, at least one variable corresponding to the operating condition upon the occurrence of the grid contingency event to facilitate determining whether the power generation and delivery system is operating properly.

3. A method in accordance with claim 1, wherein measuring at least one operating condition includes measuring at least one of a phase locked loop (PLL) error and a terminal grid voltage.

4. A method in accordance with claim 1, wherein applying the real current command signal to power converter performance comprises rapidly reducing real current

260916

output by the power converter upon receipt of a real current command signal that corresponds to a grid contingency event.

5. A method in accordance with claim 1, wherein controlling operation of the power converter based at least in part on the power command signal by increasing real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event comprises increasing real current output by the power converter by a first rate and then a second rate as a final full real current output is attained.

6. A method in accordance with claim 5, wherein the first rate of real current output by the power converter comprises a rise of 300 percent per second, or greater.

7. A method in accordance with claim 5, wherein the second rate of real current output by the power converter comprises a rise of less than 300 percent per second.

8. A method in accordance with claim 1, wherein increasing real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event comprises decreasing a likelihood of vibration tripping the wind turbine or damaging the wind turbine.

9. A method in accordance with claim 1, wherein increasing real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event comprises decreasing a likelihood of overspeed tripping the wind turbine or damaging the wind turbine.

10. A method in accordance with claim 1, wherein controlling operation of the power converter based at least in part on the power command signal by increasing real current output by the power converter in a non-uniform manner when the power

260916

command signal indicates recovery from the grid contingency event comprises increasing real current output by the power converter at least partially in a non-linear manner.

11. A method of recovering from a grid contingency event comprising:
receiving, by a controller, a power command signal, wherein the power command signal indicates recovery from the grid contingency event; and
increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response to the power command signal wherein the controller controls the power conversion assembly.

12. A method in accordance with claim 11, wherein increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response to the power command signal wherein the controller controls the power conversion assembly comprises increasing power current output by the power conversion assembly by a first rate up to a safe level for grid stability, and then at a second rate as a final full power output is attained.

13. A method in accordance with claim 12, wherein the first rate of power output by the power converter comprises a rise of 300 percent per second, or greater.

14. A method in accordance with claim 12, wherein the second rate of power output by the power converter comprises a rise of less than 300 percent per second.

15. A method in accordance with claim 11, wherein increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response to the power command signal wherein the controller controls the power conversion assembly comprises decreasing a likelihood of vibration tripping the wind turbine or damaging the wind turbine.

16. A method in accordance with claim 11, wherein increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response

260916

to the power command signal wherein the controller controls the power conversion assembly comprises decreasing a likelihood of overspeed tripping the wind turbine or damaging the wind turbine.

17. A method in accordance with claim 11, wherein increasing, in a non-uniform manner, power injected into a grid by a power conversion assembly in response to the power command signal wherein the controller controls the power conversion assembly comprises increasing power output by the power conversion assembly at least partially in a non-linear manner.

18. A power generation and distribution system comprising:

an electric generator;

a power conversion assembly coupled to said electric generator and a utility grid, said power conversion assembly configured to receive power generated by said electric generator and convert the power received to a power suitable for transmission over the utility grid, wherein said power conversion assembly is further configured to increase a real current output by said power conversion assembly in a non-uniform manner upon receipt of a real current control signal corresponding to recovery from a grid contingency event; and,

a power limiter system communicatively coupled to said power conversion assembly and configured to provide a real current control signal to said power conversion assembly, the real current control signal based at least partially on at least one measured indicator of a grid contingency event, said power limiter system comprising a memory configured to store at least one variable that corresponds to the measured indicator of a grid contingency event upon an occurrence of the grid contingency event.

19. A system in accordance with claim 18, wherein the power conversion assembly configured to increase the real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event comprises increasing real current output by the power conversion

260916

assembly by a first rate up to a safe level for grid stability, and then at a second rate as a final full real current output is attained.

20. A system in accordance with claim 18, wherein the power conversion assembly configured to increase the real current output by the power converter in a non-uniform manner when the power command signal indicates recovery from the grid contingency event comprises increasing real current output by the power conversion assembly at least partially in a non-linear manner.
