CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of U.S. Provisional Application 62/334,338 filed May 10, 2016. The entirety of this application is hereby incorporated by reference herein for all purposes.

FIELD OF THE INVENTION

This invention provides amine-linked C’-glutarimide Degronimers and Degrons for therapeutic applications as described further herein, and methods of use and compositions thereof as well as methods for their preparation.

BACKGROUND

Protein degradation is a highly regulated and essential process that maintains cellular homeostasis. The selective identification and removal of damaged, misfolded, or excess proteins is achieved via the ubiquitin-proteasome pathway (UPP). The UPP is central to the regulation of almost all cellular processes, including antigen processing, apoptosis, biogenesis of organelles, cell cycling, DNA transcription and repair, differentiation and development, immune response and inflammation, neural and muscular degeneration, morphogenesis of neural networks, modulation of cell surface receptors, ion channels and the secretory pathway, the response to stress and extracellular modulators, ribosome biogenesis and viral infection.

Covalent attachment of multiple ubiquitin molecules by an E3 ubiquitin ligase to a terminal lysine residue marks the protein for proteasome degradation, where the protein is digested into small peptides and eventually into its constituent amino acids that serve as building blocks for new proteins. Defective proteasomal degradation has been linked to a variety of clinical disorders including Alzheimer’s disease, Parkinson’s disease, Huntington’s disease, muscular dystrophies, cardiovascular disease, and cancer among others.

There are over 600 E3 ubiquitin ligases which facilitate the ubiquitination of different proteins in vivo, which can be divided into four families: HECT-domain E3s, U-box E3s,

Proteinex, Inc. filed a patent application in February 1999 that issued as U.S. Patent 6,306,663 claiming a method of generating a compound for activating the ubiquitination of a Target Protein which comprises covalently linking a Target Protein binding element able to bind specifically to the Target Protein via a ubiquitination recognition element. Proteinex described that the invention can be used to control protein levels in eukaryotes. While the "663 patent may have been based on the first patent application to describe the high level concept of how to manipulate the UPP system to degrade selected proteins in vivo, the patent did not provide sufficient detail to allow persons of skill to easily construct the range of proposed compounds. For example, for the ubiquitination recognition elements, the skilled person was told among other things to use standard methods, for drug, discovery and screen for appropriate small molecules that would bind to the ligase. Proteinex also emphasized the use of peptides as ubiquitination recognition elements, which can pose significant difficulties for oral drug administration.

Since then, harnessing the ubiquitin-proteasome pathway for therapeutic intervention has received significant interest from the scientific community. The publication by Zhou et al. from Harvard Medical School (Mol. Cell 2000, 6, 751-756) titled "Harnessing the Ubiquitination Machinery to Target the Degradation of Specific Cellular Proteins" described an engineered receptor capable of directing ubiquitination in mammalian and yeast cells.
Following from these early publications and others in the mid to late 1990s, the work of Proteinex was confirmed by Craig Crews and coworkers (Yale University) that a molecule that is capable of binding a Target Protein and a ubiquitin ligase may cause the Target Protein to be degraded. Their first description of such compounds was provided in U.S. Patent 7,041,298 filed in September 2000 by Deshaies et al. and granted in May 2006 titled “Proteolysis Targeting Chimeric Pharmaceutical”, which described a “PROTAC” consisting of a small molecule binder of MAP-AP-2 linked to a peptide capable of binding the F-box protein β-TRCP. Information in the ‘298 patent is also presented in the corresponding publication by Sakamoto et al. (Proc. Natl. Acad. Sci. USA 2001, 98, 8554-8559) titled “Protacs: Chimeric Molecules That Target Proteins to the Skp1–Cullin–F Box Complex for Ubiquitination and Degradation”. The publication by Sakamoto et al. (Mol. Cell. Proteomics 2003, 2, 1350-1358) titled “Development of Protacs to Target Cancer-Promoting Proteins for Ubiquitination and Degradation” describes an analogous PROTAC (PROTAC2) that instead of degrading MAP-AP-2 degrades estrogen and androgen receptors.

The first E3 ligase successfully targeted with a small molecule was MDM2, which ubiquitinates the tumor suppressor p53. The targeting ligand was an HDM2/MDM2 inhibitor identified in Vassilev et al. (Science 2004, 303, 844-848) titled “In Vivo Activation of the P53 Pathway by Small-Molecule Antagonists of MDM2”.

Other examples of direct small molecule-induced recruitment of Target Proteins to the proteasome for degradation on addition to cultured cells were described in 2004 (Schneekloth et al. (J. Am. Chem. Soc. 2004, 126, 3748-3754) titled “Chemical Genetic Control of Protein Levels: Selective in Vivo Targeted Degradation”). Schneekloth et al. describe a degradation agent (PROTAC3) that targets the FK506 binding protein (FKBP12) and shows that both PROTAC2 and PROTAC3 hit their respective targets with green fluorescent protein (GFP) imaging. The publication by Schneekloth et al. (ChemBioChem 2005, 6, 40-46) titled “Chemical Approaches to Controlling Intracellular Protein Degradation” described the state of the field at the time.

The publication by Schneekloth et al. (Bioorg. Med. Chem. Lett. 2008, 18, 5904-5908) titled “Targeted Intracellular Protein Degradation Induced by a Small Molecule: In Route to Chemical Proteomics” describes a degradation agent that consists of two small molecules linked by PEG that in vivo degrades the androgen receptor by concurrently binding the androgen receptor and ubiquitin E3 ligase.
WO 2013/170147 filed by Crews et al. titled “Compounds Useful for Promoting Protein Degradation and Methods of Using Same” describes compounds comprising a protein degradation moiety covalently bound to a linker, wherein the ClogP of the compound is equal to or higher than 1.5. In particular, the specification discloses protein degrading compounds that incorporate certain small molecules that can bind to an E3 ubiquitin ligase.

In unrelated parallel research, scientists were investigating thalidomide toxicity. Ito et al. (Science 2010, 327, 1345-1350) titled "Identification of a Primary Target of Thalidomide Teratogenicity", described that cereblon is a thalidomide binding protein. Cereblon forms part of an E3 ubiquitin ligase protein complex which interacts with damaged DNA binding protein 1, forming an E3 ubiquitin ligase complex with Cul4 and the E2-binding protein ROC1 (also known as RBX1) where it functions as a substrate receptor to select proteins for ubiquitination. The study revealed that thalidomide-cereblon binding in vivo may be responsible for thalidomide teratogenicity. After the discovery that thalidomide causes teratogenicity in the mid-1960’s, the compound and related structures were notwithstanding found to be useful as anti-inflammatory, anti-angiogenic and anti-cancer agents (see Bartlett et al. (Nat. Rev. Cancer 2004, 4, 314-322) titled "The Evolution of Thalidomide and Its Imid Derivatives as Anticancer Agents").

The disclosure that thalidomide binds to the cereblon E3 ubiquitin ligase led to research to investigate incorporating thalidomide and certain derivatives into compounds for the targeted destruction of proteins. Two seminal papers were published in Science in 2014: G. Lu et al., The Myeloma Drug Lenalidomide Promotes the Cereblon-Dependent Destruction of Ikaros Proteins, Science, 343, 305-309 (2014); and J. Kronke et al., Lenalidomide Causes Selective Degradation of IKZF1 and IKZF3 in Multiple Myeloma Cells, Science, 343, 301-305 (2014).

U.S. 2014/0356322 assigned to Yale University, GlaxoSmithKline, and Cambridge Enterprise Limited University of Cambridge titled “Compounds and Methods for the Enhanced Degradation of Target Proteins & Other Polypeptides by an E3 Ubiquitin Ligase” describes protein degrading compounds that bind to the VHL E3 Ubiquitin Ligase. See also Buckley et al. (J. Am. Chem. Soc. 2012, 134, 4465-4468) titled "Targeting the Von Hippel-Lindau E3 Ubiquitin Ligase Using Small Molecules to Disrupt the Vhl/Hif-1alpha Interaction".

Dana-Farber Cancer Institute has also filed several patent applications directed to the degradation of a Target Protein using known E3 ligase ligands to direct the Target Protein to the proteasome for degradation. These filings include US 2016/0176916 titled “Methods to Induce Target Protein Degradation through Bifunctional Molecules; WO 2017/024318 titled “Target Protein Degradation to Attenuate Adoptive T-Cell Therapy Associated Adverse Inflammatory Responses”; WO 2017/024317 titled “Methods to Induce Target Protein Degradation through

While progress has been made in the area of modulation of the UPP for in vivo protein degradation, it would be useful to have additional compounds and approaches to more fully harness the UPP for therapeutic treatments.

It is an object of the present invention to provide new compounds, methods, compositions, and methods of manufacture that are useful to degrade selected proteins in vivo.

SUMMARY

Compounds and their uses and manufacture are provided that cause degradation of a selected protein via the ubiquitin proteasome pathway (UPP). N(substituted)2-C’-glutarimides (wherein one substituent can be hydrogen) and analogues thereof are described (Degrons) that bind an E3 ligase (typically the cereblon subunit). Degronmers are disclosed of Formulas I, II and V that include a “Targeting Ligand” that binds (typically non-covalently) to a selected Target Protein, a “Degron” which binds (typically non-covalently) to an E3 Ligase (typically via cereblon) and optionally a Linker that covalently links the Targeting Ligand to the Degron.

A Degronimer provided herein or its pharmaceutically acceptable salt and/or its pharmaceutically acceptable composition can be used to treat a disorder which is mediated by the selected Target Protein that binds to the Targeting Ligand. Therefore, in some embodiments a method to treat a host with a disorder mediated by the Target Protein is provided that includes administering an effective amount of the Degronimer or its pharmaceutically acceptable salt described herein to the host, typically a human, optionally in a pharmaceutically acceptable composition.

In one embodiment, the selected Target Protein is derived from a gene that has undergone an amplification, translocation, deletion, or inversion event which causes or is caused by a medical disorder. In an alternative embodiment, the Target Protein can be covalently modified by a Targeting Ligand that
has been functionalized to create a covalent bond with the Target Protein, and the covalently bond can be irreversible or reversible.

The structure of the Degronimer is typically selected such that it is sufficiently stable to sustain a shelf life of at least two, three, four, or five months under ambient conditions. To accomplish this, each of the R groups described herein must be sufficiently stable to sustain the corresponding desired shelf life of at least two, three, four or five months under ambient conditions. One of ordinary skill in the art is well aware of the stability of chemical moieties and can avoid those that are not stable or are too reactive under the appropriate conditions.

The Degronimer (Degron, Linker and Targeting Ligand), including any of the "R" groups defined herein, may be optionally substituted as described below in Section I: Definitions, if desired to achieve the target effect, results in a stable R moiety and final compound that makes chemical sense to the routineer, and if a final compound for therapy, is pharmaceutically acceptable. Also, all R groups, with or without optional substituents, should be interpreted in a manner that does not include redundancy (i.e., as known in the art, alkyl substituted with alkyl is redundant; however for examples, alkoxy substituted with alkoxy is not redundant).

Linker is a chemical group that attaches the Degron to a Targeting Ligand.

Targeting Ligand is a small molecule that binds to a Target Protein, and wherein the Target Protein is a mediator of disease in a host.

Degronimers of Formula I, Formula II, and Formula V are bifunctional compounds with an amine. E3 Ubiquitin Ligase targeting moiety (Degron) linked to protein Targeting Ligand (described in more detail below), which function to recruit Target Proteins, typically via a cereblon-containing E3 Ubiquitin Ligase for degradation. One non-limiting example of a disorder treatable by such compounds is abnormal cellular proliferation, such as a tumor or cancer, wherein the Target Protein is an oncogenic protein or a signaling mediator of an abnormal cellular proliferative pathway and its degradation decreases abnormal cell growth.

Based on this discovery, compounds and methods are presented for the treatment of a patient with a disorder mediated by a protein that is targeted for selective degradation.
administering an effective amount of one or a combination of the Degronimers of Formula I, Formula II, or Formula V described herein to a patient (typically a human) in need thereof, optionally in a pharmaceutically acceptable carrier (composition). In certain embodiments the disorder is selected from a benign growth, neoplasm, tumor, cancer, abnormal cellular proliferation, immune disorder, autoimmune disorder, inflammatory disorder, graft-versus-host rejection, viral infection, bacterial infection, an amyloid-based proteinopathy, a proteinopathy, or fibrotic disorder. In a typical embodiment the patient is a human.

In one embodiment, the present invention provides N(substituted)2-C'-glutarimides and defined analogue Degrons thereof which are covalently linked to a Targeting Ligand through a Linker which can be of varying length and functionality. In one embodiment, the N(substituted)2-C'-glutarimides and defined analogue Degron is linked directly to the Targeting Ligand (i.e., the Linker is a bond). In certain embodiments, the Linker can be any chemically stable group that attaches the amine Degron to the Targeting Ligand. In a typical embodiment the Linker has a chain of 2 to 14, 15, 16, 17, 18 or 20 or more carbon atoms of which one or more carbons can be replaced by a heteroatom such as O, N, S, P, as long as the resulting molecule has a stable shelf life for at least 2 months, 3 months, 6 months or 1 year as part of a pharmaceutically acceptable dosage form, and itself is pharmaceutically acceptable. In certain embodiments the chain has 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, or 14 contiguous atoms in the chain. For example, the chain may include 1 or more ethylene glycol units, and in some embodiments, may have at least 2, 3, 4, 5, 6, 7, 8, 9, or 10 or more contiguous, partially contiguous or non-contiguous ethylene glycol units in the Linker. In certain embodiments the chain has at least 1, 2, 3, 4, 5, 6, 7, or 8 branches which can be independently alkyl, heteroalkyl, aryl, heteroaryl, alkenyl, or alkynyl substituents, which in one embodiment, each branch has 10, 8, 6, 4, 3, 2 carbons or one carbon.

In one embodiment, the Target Protein is a protein that is not drugable in the classic sense in that it does not have a binding pocket or an active site that can be inhibited or otherwise bound, and cannot be easily allosterically controlled. In another embodiment, the Target Protein is a protein that is drugable in the classic sense. Examples of Target Proteins are provided below.

In an alternative embodiment, an N(substituted)2-C'-glutarimide as described herein can be used alone (i.e., not as part of a Degronimer) as an in vivo binder of cereblon, which can be administered to a host, for example, a human, in need thereof, in an effective amount, optionally as a pharmaceutically acceptable salt, and optionally in a pharmaceutically acceptable
composition, for any therapeutic indication which can be treated by modulating the function and or activity of the cereblon-containing E3 Ubiquitin Ligase Protein Complex, including but not limited to uses known for the cereblon binders thalidomide, pomalidomide or lenalidomide. In certain alternative embodiments, the compound of Formula III or IV can activate, decrease or change the natural activity of cereblon. Nonlimiting examples of uses for cereblon binders are multiple myeloma, a hematological disorder such as myelodysplastic syndrome, cancer, tumors, abnormal cellular proliferation, HIV/AIDS, Crohn’s disease, sarcoidosis, graft-versus-host disease, rheumatoid arthritis, Behcet’s disease, tuberculosis, and myelofibrosis.

DETAILED DESCRIPTION

I. DEFINITIONS

Compounds are described using standard nomenclature. Unless defined otherwise, all technical and scientific terms used herein have the same meaning as is commonly understood by one of skill in the art to which this invention belongs.

The compounds in any of the Formulas described herein may be in the form of a racemate, enantiomer, mixture of enantiomers, diastereomer, mixture of diastereomers, tautomer, N-oxide, isomer; such as rotamer, as if each is specifically described unless specifically excluded by context.

The terms “a” and “an” do not denote a limitation of quantity, but rather denote the presence of at least one of the referenced item. The term “or” means “and/or”. Recitation of ranges of values are merely intended to serve as a shorthand method of referring individually to each separate value falling within the range, unless otherwise indicated herein, and each separate
value is incorporated into the specification as if it were individually recited herein. The endpoints of all ranges are included within the range and independently combinable. All methods described herein can be performed in a suitable order unless otherwise indicated herein or otherwise clearly contradicted by context. The use of examples, or exemplary language (e.g., “such as”), is intended merely to better illustrate the invention and does not pose a limitation on the scope of the invention unless otherwise claimed.

The present invention includes compounds of Formula I, Formula II, Formula III, and Formula IV with at least one desired isotopic substitution of an atom, at an amount above the natural abundance of the isotope, i.e., enriched. Isotopes are atoms having the same atomic number but different mass numbers, i.e., the same number of protons but a different number of neutrons. Examples of isotopes that can be incorporated into compounds of the invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorous, fluorine, chlorine and iodine such as ²H, ³H, ¹¹C, ¹²C, ¹³C, ¹⁴C, ¹⁸F, ¹⁹F, ³¹P, ³²P, ³³S, ³⁵Cl, and ¹²⁷I respectively. In one non-limiting embodiment, isotopically labelled compounds can be used in metabolic studies (with, for example ¹⁴C), reaction kinetic studies (with, for example ¹H or ³H), detection or imaging techniques, such as positron emission tomography (PET) or single-photon emission computed tomography (SPECT) including drug or substrate tissue distribution assays, or in radioactive treatment of patients. In particular, an ¹⁸F labeled compound may be particularly desirable for PET or SPECT studies. Isotopically labeled compounds of this invention and prodrugs thereof can generally be prepared by carrying out the procedures disclosed in the schemes or in the examples and preparations described below by substituting a readily available isotopically labeled reagent for a non-isotopically labeled reagent.

Isotopic substitutions, for example deuterium substitutions, can be partial or complete. Partial deuterium substitution means that at least one hydrogen is substituted with deuterium. In certain embodiments, the isotope is 90, 95 or 99% or more enriched in the isotope at any location of interest. In one non-limiting embodiment, deuterium is 90, 95 or 99% enriched at a desired location.

In one non-limiting embodiment, the substitution of a hydrogen atom for a deuterium atom can be provided in any compound of Formula I-V. In one non-limiting embodiment, the substitution of a hydrogen atom for a deuterium atom occurs within one or more groups selected from any of R’s or variables described herein, Linker, and Targeting Ligand. For example, when
any of the groups are, or contain for example through substitution, methyl, ethyl, or methoxy, the alkyl residue may be deuterated (in non-limiting embodiments, CDH₂, CD₂H, CD₃, CH₂CD₃, CH₃CD₂, CHDCH₂D, CH₂CD₃, CHDCHD₂, OCDH₂, OCD₂H, or OCD, etc.). In certain other embodiments, when two substituents are combined to form a cycle the unsubstituted carbons may be deuterated.

The compound of the present invention may form a solvate with a solvent (including water). Therefore, in one non-limiting embodiment, the invention includes a solvated form of the compound. The term "solvate" refers to a molecular complex of a compound of the present invention (including a salt thereof) with one or more solvent molecules. Non-limiting examples of solvents are water, ethanol, isopropanol, dimethyl sulfoxide, acetone and other common organic solvents. The term "hydrate" refers to a molecular complex comprising a compound of the invention and water. Pharmaceutically acceptable solvates in accordance with the invention include those wherein the solvent may be isotopically substituted, e.g. D₂O, d₆-acetone, d₆-DMSO. A solvate can be in a liquid or solid form.

A dash ("-") that is not between two letters or symbols is used to indicate a point of attachment for a substituent. For example, -(C=O)NH, is attached through carbon of the carbonyl (C=O) group.

"Alkyl" is a branched or straight chain saturated aliphatic hydrocarbon group. In one non-limiting embodiment, the alkyl group contains from 1 to about 12 carbon atoms, more generally from 1 to about 6 carbon atoms or from 1 to about 4 carbon atoms. In one non-limiting embodiment, the alkyl contains from 1 to about 8 carbon atoms. In certain embodiments, the alkyl is C₁-C₆alkyl as used herein indicates a straight or branched alkyl group having each member of the range described as an independent species. For example, the term C₁-C₆alkyl as used herein indicates a straight or branched alkyl group having from 1, 2, 3, 4, 5, or 6 carbon atoms, and is intended to mean that each of these is described as an independent species and therefore each subset is considered separately disclosed. For example, the term C₁-C₆alkyl as used herein indicates a straight or branched alkyl group having from 1, 2, 3, or 4 carbon atoms and is intended to mean that each of these is described as an independent species. Examples of alkyl include, but are not limited to, methyl, ethyl, n-propyl, isopropyl, n-butyl, isobutyl, sec-butyl, tert-butyl, n-pentyl, isopentyl, neopentyl, n-hexyl, 2-methylpentane, 3-methylpentane, 2,2-dimethylbutane, and 2,3-dimethylbutane. In an alternative embodiment, the alkyl group is

Linker

A Linker is included in the Degronimers of Formula I, II, V and VII. Linker is a bond or a chemically stable group that attaches a Degron to a Targeting Ligand.

Any of the Linkers described herein can be used in either direction, i.e., either the left end is linked to the Degron and the right end to the Target Linker, or the left end is linked to the Target Linker and the right end is linked to the Degron. According to the invention, any desired linker can be used as long as the resulting compound has a stable shelf life for at least 2 months, 3 months,
6 months or 1 year as part of a pharmaceutically acceptable dosage form, and itself is pharmaceutically acceptable.

In a typical embodiment, the Linker has a chain of 2 to 14, 15, 16, 17, 18 or 20 or more carbon atoms of which one or more carbons can be replaced by a heteroatom such as O, N, S, or P. In certain embodiments the chain has 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19 or 20 contiguous atoms in the chain. For example, the chain may include 1 or more ethylene glycol units that can be contiguous, partially contiguous or non-contiguous (for example, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 or 12 ethylene glycol units). In certain embodiments the chain has at least 1, 2, 3, 4, 5, 6, 7, or 8 contiguous chains which can have branches which can be independently alkyl, heteroalkyl, aryl, heteroaryl, alkenyl, or alkynyl, aliphatic, heteroaliphatic, cycloalkyl or heterocyclic substituents.

In other embodiments, the linker can include or be comprised of one or more of ethylene glycol, propylene glycol, lactic acid and/or glycolic acid. In general, propylene glycol adds hydrophobicity, while propylene glycol adds hydrophilicity. Lactic acid segments tend to have a longer half-life than glycolic acid segments. Block and random lactic acid-co-glycolic acid moieties, as well as ethylene glycol and propylene glycol, are known in the art to be pharmaceutically acceptable and can be modified or arranged to obtain the desired half-life and hydrophilicity. In certain aspects, these units can be flanked or interspersed with other moieties, such as aliphatic, including alkyl, heteroaliphatic, aryl, heteroaryl, heterocyclic, cycloalkyl, etc., as desired to achieve the appropriate drug properties.

In one embodiment, the Linker is a moiety selected from Formula LI, Formula LII, Formula LIII, Formula LIV, Formula LV, Formula LVI, and Formula LVII:

Target Proteins

Degradation of cellular proteins is required for cell homeostasis and normal cell function, such as proliferation, differentiation and cell death. When this system becomes dysfunctional or does not identify and abate abnormal protein behavior in vivo, a disease state can arise in a host, such as a human. A large range of proteins can cause, modulate or amplify diseases in vivo, as well known to those skilled in the art, published in literature and patent filings as well as presented in scientific presentations.

Therefore, in one embodiment, a selected Degronimer compound of the present invention can be administered in vivo in an effective amount to a host in need thereof to degrade a selected protein that mediates a disorder to be treated. The selected protein target may modulate a disorder in a human via a mechanism of action such as modification of a biological pathway, pathogenic signaling or modulation of a signal cascade or cellular entry. In one embodiment, the Target
Protein is a protein that is not drugable in the classic sense in that it does not have a binding pocket or an active site that can be inhibited or otherwise bound, and cannot be easily allosterically controlled. In another embodiment, the Target Protein is a protein that is drugable in the classic sense, yet for therapeutic purposes, degradation of the protein is preferred to inhibition.

The Target Protein is recruited with a Targeting Ligand, which is a ligand for the Target Protein. Typically the Targeting Ligand binds the Target Protein in a non-covalent fashion. In an alternative embodiment, the Target Protein is covalently bound to the Degron in a manner that can be irreversible or reversible.

In one embodiment, the selected Target Protein is expressed from a gene that has undergone an amplification, translocation, deletion, or inversion event which causes or is caused by a medical disorder. In certain aspects, the selected Target Protein has been post-translationally modified by one, or a combination, of phosphorylation, acetylation, acylation including propionylation and crotylation, N-linked glycosylation, amidation, hydroxylation, methylation and poly-methylation, O-linked glycosylation, pyroglycotamoylation, myristoylation, farnesylation, geranylgeranylation, ubiquitination, sumoylation, or sulfation which causes or is caused by a medical disorder.

As contemplated herein, the present invention includes an Degronimer with a Targeting Ligand that binds to a Target Protein of interest. The Target Protein is any amino acid sequence to which an Degronimer can be bound which by degradation thereof, causes a beneficial therapeutic effect in vivo. In one embodiment, the Target Protein is a non-endogenous peptide such as that from a pathogen or toxin. In another embodiment, the Target Protein can be an endogenous protein that mediates a disorder. The endogenous protein can be either the normal form of the protein or an aberrant form. For example, the Target Protein can be a mutant protein found in cancer cells, or a protein, for example, where a partial, or full, gain-of-function or loss-of-function is encoded by nucleotide polymorphisms. In some embodiments, the Degronimer targets the aberrant form of the protein and not the normal form of the protein. In another embodiment, the Target Protein can mediate an inflammatory disorder or an immune disorder, including an auto-immune disorder. In one embodiment, the Target Protein is a non-endogenous protein from a virus, as non-limiting examples, HIV, HBV, HCV, RSV, HPV, CMV, flavivirus, pestivirus, coronavirus, noroviridae, etc. In one embodiment, the Target Protein is a non-endogenous protein from a bacteria, which may be, for example, a gram positive bacteria, gram negative bacteria or other, and can be a drug-
resistant form of bacteria. In one embodiment, the Target Protein is a non-endogenous protein from a fungus. In one embodiment, the Target Protein is a non-endogenous protein from a prion. In one embodiment, the Target Protein is a protein derived from a eukaryotic pathogen, for example a protist, helminth, etc.

In one aspect, the Target Protein mediates chromatin structure and function. The Target Protein may mediate an epigenetic action such as DNA methylation or covalent modification of histones. An example is histone deacetylase (HDAC 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 or 11). Alternatively, the Target Protein may be a bromodomain, which are readers of lysine acetylation (for example, BRD1, 2, 3, 4, 5, 6, 7, 8, 9 and T. FIG. 9 illustrates the proteins of the bromodomain family, which, for example, can act as Target Proteins according to the present invention.

In one embodiment, the Target Protein is a modulator of a signaling cascade related to a known disease state. lecule or moiety (for example a peptide, nucleotide, antibody, antibody fragment, aptamer, biomolecule or other chemical structure) that binds to a Target Protein, and wherein the Target Protein is a mediator of disease in a host as described in detail below.

Target Ligands

II. METHODS OF TREATMENT

The N(substituted)2-C'-glutarimide or defined analogue thereof of Formula I, III, IV and V can be used in an effective amount to treat a host, including a human, in need thereof, optionally in a pharmaceutically acceptable carrier to treat any of the disorders described herein.

The terms “treat”, “treating”, and “treatment”, etc., as used herein, refer to any action providing a benefit to a patient for which the present compounds may be administered, including the treatment of any disease state or condition which is modulated through the protein to which the present compounds bind. Illustrative non-limiting disease states or conditions, including cancer, which may be treated using compounds according to the present invention are set forth hereinabove.

The N(substituted)2-C'-glutarimide or defined analogue thereof of Formula I and Formula II compositions as described herein can be used to degrade a Target Protein which is a mediator of the disorder affecting the patient, such as a human. The control of protein level afforded by the Formula I, Formula II, or Formula V Degronimers of the present invention provides treatment of a disease state or condition, which is modulated through the Target Protein by lowering the level of that protein in the cell, e.g., cell of a patient. In certain embodiments, the method comprises administering an effective amount of the compound as described herein, optionally including a pharmaceutically acceptable excipient, carrier, adjuvant, i.e., a pharmaceutically acceptable composition, optionally in combination with another bioactive agent or combination of agents.

The term “disease state or condition” when used in connection with a Formula I, Formula II, or Formula V compound is meant to refer to any disease state or condition wherein protein dysregulation (i.e., the amount of protein expressed in a patient is elevated) occurs via a Target Protein, and where degradation of such protein in a patient may provide beneficial therapy or relief of symptoms to a patient in need thereof. In certain instances, the disease state or condition may be cured. The compounds of Formula I and Formula II, are for example useful as therapeutic
agents when administered in an effective amount to a host, including a human, to treat a myelo-or lymphoproliferative disorder such as B- or T-cell lymphomas, multiple myeloma, Waldenstrom’s macroglobulinemia, Wiskott-Aldrich syndrome, or a post-transplant lymphoproliferative disorder; an immune disorder, including autoimmune disorders such as Addison disease, Celiac disease, dermatomyositis, Graves disease, thyroiditis, multiple sclerosis, pernicious anemia, reactive arthritis, lupus, or type I diabetes; a disease of cardiologic malfunction, including hypercholesterolemia; an infectious disease, including viral and/or bacterial infections; an inflammatory condition, including asthma, chronic peptic ulcers, tuberculosis, rheumatoid arthritis, periodontitis, ulcerative colitis, Crohn’s disease, or hepatitis.

The term “disease state or condition” when used in connection with a Formula III or Formula IV compound for example, refers to any therapeutic indication which can be treated by decreasing the activity of cereblon or a cereblon-containing E3 Ligase, including but not limited to uses known for the cereblon binders thalidomide, pomalidomide or lenalidomide. Nonlimiting examples of uses for cereblon binders are multiple myeloma, a hematological disorder such as myelodysplastic syndrome, cancer, tumor, abnormal cellular proliferation, HIV/AIDS, HBV, HCV, hepatitis, Crohn’s disease, sarcoidosis, graft-versus-host disease, rheumatoid arthritis, Behcet’s disease, tuberculosis, and myelofibrosis. Other indications include a myelo- or lymphoproliferative disorder such as B- or T-cell lymphomas, Waldenstrom’s macroglobulinemia, Wiskott-Aldrich syndrome, or a post-transplant lymphoproliferative disorder; an immune disorder, including autoimmune disorders such as Addison disease, Celiac disease, dermatomyositis, Graves disease, thyroiditis, multiple sclerosis, pernicious anemia, arthritis, and in particular rheumatoid arthritis, lupus, or type I diabetes; a disease of cardiologic malfunction, including hypercholesterolemia; an infectious disease, including viral and/or bacterial infection, as described generally herein; an inflammatory condition, including asthma, chronic peptic ulcers, tuberculosis, rheumatoid arthritis, periodontitis and ulcerative colitis.

In certain embodiments, the present invention provides for administering a compound of Formulas I, II, III or IV to a method of treating a patient, for example, a human, having an infectious disease, wherein the therapy targets a protein of the infectious agent, optionally in combination with another bioactive agent. The disease state or condition may be a disease caused by a microbial agent or other exogenous agent such as a virus (as non-limiting examples, HIV, HBV, HCV, HSV, HPV, RSV, CMV, Ebola, Flavivirus, Pestivirus, Rotavirus, Influenza,
Coronavirus, EBV, viral pneumonia, drug-resistant viruses, Bird flu, RNA virus, DNA virus, adenovirus, poxvirus, Picornavirus, Togavirus, Orthomyxovirus, Retrovirus or Hepadnavirus, bacteria (Gram-negative, Gram-positive, fungus, protozoa, helminth, worms, prion, parasite, or other microbe or may be a disease state, which is caused by overexpression of a protein, which leads to a disease state and/or condition.

In certain embodiments, the condition treated with a compound of the present invention is a disorder related to abnormal cellular proliferation. Abnormal cellular proliferation, notably hyperproliferation, can occur as a result of a wide variety of factors, including genetic mutation, infection, exposure to toxins, autoimmune disorders, and benign or malignant tumor induction.

There are a number of skin disorders associated with cellular hyperproliferation. Psoriasis, for example, is a benign disease of human skin generally characterized by plaques covered by thickened scales. The disease is caused by increased proliferation of epidermal cells of unknown cause. Chronic eczema is also associated with significant hyperproliferation of the epidermis. Other diseases caused by hyperproliferation of skin cells include atopic dermatitis, lichen planus, warts, pemphigus vulgaris, actinic keratosis, basal cell carcinoma and squamous cell carcinoma.

Other hyperproliferative cell disorders include blood vessel proliferation disorders, fibrotic disorders, autoimmune disorders, graft-versus-host rejection, tumors and cancers.

Blood vessel proliferative disorders include angiogenic and vasculogenic disorders. Proliferation of smooth muscle cells in the course of development of plaques in vascular tissue cause, for example, restenosis, retinopathies and atherosclerosis. Both cell migration and cell proliferation play a role in the formation of atherosclerotic lesions.

Fibrotic disorders are often due to the abnormal formation of an extracellular matrix. Examples of fibrotic disorders include hepatic cirrhosis and mesangial proliferative cell disorders. Hepatic cirrhosis is characterized by the increase in extracellular matrix constituents resulting in the formation of a hepatic scar. Hepatic cirrhosis can cause diseases such as cirrhosis of the liver. An increased extracellular matrix resulting in a hepatic scar can also be caused by viral infection such as hepatitis. Lipocytes appear to play a major role in hepatic cirrhosis.

Mesangial disorders are brought about by abnormal proliferation of mesangial cells. Mesangial hyperproliferative cell disorders include various human renal diseases, such as glomerulonephritis, diabetic nephropathy, malignant nephrosclerosis, thrombotic microangiopathy syndromes, transplant rejection, and glomerulopathies.
Another disease with a proliferative component is rheumatoid arthritis. Rheumatoid arthritis is generally considered an autoimmune disease that is thought to be associated with activity of autoreactive T cells, and to be caused by autoantibodies produced against collagen and IgE.

Other disorders that can include an abnormal cellular proliferative component include Bechet's syndrome, acute respiratory distress syndrome (ARDS), ischemic heart disease, post-dialysis syndrome, leukemia, acquired immune deficiency syndrome, vasculitis, lipid histiocytosis, septic shock and inflammation in general.

Cutaneous contact hypersensitivity and asthma are just two examples of immune responses that can be associated with significant morbidity. Others include atopic dermatitis, eczema, Sjogren's Syndrome, including keratoconjunctivitis sicca secondary to Sjogren's Syndrome, alopecia areata, allergic responses due to arthropod bite reactions, Crohn's disease, aphthous ulcer, iritis, conjunctivitis, keratoconjunctivitis, ulcerative colitis, cutaneous lupus erythematosus, scleroderma, vaginitis, proctitis, and drug eruptions. These conditions may result in any one or more of the following symptoms or signs: itching, swelling, redness, blisters, crusting, ulceration, pain, scaling, cracking, hair loss, scarring, or oozing of fluid involving the skin, eye, or mucosal membranes.

In atopic dermatitis, and eczema in general, immunologically mediated leukocyte infiltration (particularly infiltration of mononuclear cells, lymphocytes, neutrophils, and eosinophils) into the skin importantly contributes to the pathogenesis of these diseases. Chronic eczema also is associated with significant hyperproliferation of the epidermis. Immunologically mediated leukocyte infiltration also occurs at sites other than the skin, such as in the airways in asthma and in the tear producing gland of the eye in keratoconjunctivitis sicca.

In one non-limiting embodiment compounds of the present invention are used as topical agents, in treating contact dermatitis, atopic dermatitis, eczematous dermatitis, psoriasis, Sjogren's Syndrome, including keratoconjunctivitis sicca secondary to Sjogren's Syndrome, alopecia areata, allergic responses due to arthropod bite reactions, Crohn's disease, aphthous ulcer, iritis, conjunctivitis, keratoconjunctivitis, ulcerative colitis, asthma, allergic asthma, cutaneous lupus erythematosus, scleroderma, vaginitis, proctitis, and drug eruptions. The novel method may also be useful in reducing the infiltration of skin by malignant leukocytes in diseases such as mycosis fungoides. These compounds can also be used to treat an aqueous-deficient dry eye state (such as
immune mediated keratoconjunctivitis) in a patient suffering therefrom, by administering the
compound topically to the eye.

present invention include, for example, asthma, autoimmune diseases such as multiple sclerosis,

Malignant neoplasms show partial or complete lack of structural organization and functional coordination with the normal tissue and most invade surrounding tissues, metastasize to several sites, and are likely to recur after attempted removal and to cause the death of the patient unless adequately treated. As used herein, the term neoplasia is used to describe all cancerous disease states and embraces or encompasses the pathological process associated with malignant hematogenous, ascitic and solid tumors. In one embodiment, the additional therapy is a monoclonal antibody (MAb). Some MAbs stimulate an immune response that destroys cancer cells. Similar to the antibodies produced naturally by B cells, these MAbs may “coat” the cancer cell surface, triggering its destruction by the immune system. For example, bevacizumab targets vascular endothelial growth factor (VEGF), a protein secreted by tumor cells and other cells in the tumor’s microenvironment that promotes the development of tumor blood vessels. When bound to bevacizumab, VEGF cannot interact with its cellular receptor, preventing the signaling that leads to the growth of new blood vessels. Similarly, cetuximab and panitumumab target the epidermal growth factor receptor (EGFR), and trastuzumab targets the human epidermal growth factor receptor 2 (HER-2). MAbs that bind to cell surface growth factor receptors prevent the targeted receptors from sending their normal growth-promoting signals. They may also trigger apoptosis and activate the immune system to destroy tumor cells.

In one aspect of the present invention, the bioactive agent is an immunosuppressive agent. The immunosuppressive agent can be a calcineurin inhibitor, e.g. a cyclosporin or an ascomycin, e.g. Cyclosporin A (NEORAL®), FK506 (tacrolimus), pimecrolimus, a mTOR inhibitor, e.g. rapamycin or a derivative thereof, e.g. Sirolimus (RAPAMUNE®), Everolimus (Certican®), temsirolimus, zotarolimus, biolimus-7, biolimus-9, a rapalog, e.g. ridaforolimus, azathioprine,

IV. PHARMACEUTICAL COMPOSITIONS

The N(substituted)L-glutarimide compounds of Formula I, II, III, IV and V as disclosed herein can be administered as the neat chemical, but are more typically administered as a pharmaceutical composition, that includes an effective amount for a host, typically a human, in need of such treatment for any of the disorders described herein. Accordingly, the disclosure provides pharmaceutical compositions comprising an effective amount of compound or pharmaceutically acceptable salt together with at least one pharmaceutically acceptable carrier for any of the uses described herein. The pharmaceutical composition may contain a compound or salt as the only active agent, or, in an alternative embodiment, the compound and at least one additional active agent.

In certain embodiments the pharmaceutical composition is in a dosage form that contains from about 0.1 mg to about 2000 mg, from about 10 mg to about 1000 mg, from about 100 mg to about 800 mg, or from about 200 mg to about 600 mg of the active compound and optionally from about 0.1 mg to about 2000 mg, from about 10 mg to about 1000 mg, from about 100 mg to about 800 mg, or from about 200 mg to about 600 mg of an additional active agent in a unit dosage form. Examples are dosage forms with at least 0.1, 1, 5, 10, 25, 50, 100, 200, 250, 300, 400, 500, 600, 700, or 750 mg of active compound, or its salt. The pharmaceutical composition may also include a molar ratio of the active compound and an additional active agent. For example the
pharmaceutical composition may contain a molar ratio of about 0.5:1, about 1:1, about 2:1, about 3:1 or from about 1.5:1 to about 4:1 of an anti-inflammatory or immunosuppressing agent. Compounds disclosed herein may be administered orally, topically, parenterally, by inhalation or spray, sublingually, via implant, including ocular implant, transdermally, via buccal administration, rectally, as an ophthalmic solution, injection, including ocular injection, intravenous, intra-aortal, intracranial, subdermal, intraperitoneal, subcutaneous, transnasal, sublingual, or rectal or by other means, in dosage unit formulations containing conventional pharmaceutically acceptable carriers. For ocular delivery, the compound can be administered, as desired, for example, via intravitreal, intrastromal, intracameral, sub-tenon, sub-retinal, retrobulbar, peribulbar, suprachoroidal, conjunctival, subconjunctival, episcleral, periorcular, transscleral, retrobulbar, posterior juxtascleral, circumcorneal, or tear duct injections, or through a mucus, mucin, or a mucosal barrier, in an immediate or controlled release fashion or via an ocular device.

The pharmaceutical composition may be formulated as any pharmaceutically useful form, e.g., as an aerosol, a cream, a gel, a pill, an injection or infusion solution, a capsule, a tablet, a syrup, a transdermal patch, a subcutaneous patch, a dry powder, an inhalation formulation, in a medical device, suppository, buccal, or sublingual formulation, parenteral formulation, or an ophthalmic solution. Some dosage forms, such as tablets and capsules, are subdivided into suitably sized unit doses containing appropriate quantities of the active components, e.g., an effective amount to achieve the desired purpose.

Carriers include excipients and diluents and must be of sufficiently high purity and sufficiently low toxicity to render them suitable for administration to the patient being treated. The carrier can be inert or it can possess pharmaceutical benefits of its own. The amount of carrier employed in conjunction with the compound is sufficient to provide a practical quantity of material for administration per unit dose of the compound.

Classes of carriers include, but are not limited to binders, buffering agents, coloring agents, diluents, disintegrants, emulsifiers, flavorants, glidants, lubricants, preservatives, stabilizers, surfactants, tableting agents, and wetting agents. Some carriers may be listed in more than one class, for example vegetable oil may be used as a lubricant in some formulations and a diluent in others. Exemplary pharmaceutically acceptable carriers include sugars, starches, celluloses, powdered tragacanth, malt, gelatin; talc, and vegetable oils. Optional active agents may be
included in a pharmaceutical composition, which do not substantially interfere with the activity of
the compound of the present invention.

The pharmaceutical compositions/combinations can be formulated for oral administration. These compositions can contain any amount of active compound that achieves the desired result, for example between 0.1 and 99 weight % (wt.%) of the compound and usually at least about 5 wt.% of the compound. Some embodiments contain from about 25 wt.% to about 50 wt.% or from about 5 wt.% to about 75 wt.% of the compound.

Formulations suitable for rectal administration are typically presented as unit dose suppositories. These may be prepared by admixing the active compound with one or more conventional solid carriers, for example, cocoa butter, and then shaping the resulting mixture.

Formulations suitable for topical application to the skin preferably take the form of an ointment, cream, lotion, paste, gel, spray, aerosol, or oil. Carriers which may be used include petroleum jelly, lanoline, polyethylene glycols, alcohols, transdermal enhancers, and combinations of two or more thereof.

Formulations suitable for transdermal administration may be presented as discrete patches adapted to remain in intimate contact with the epidermis of the recipient for a prolonged period of time. Formulations suitable for transdermal administration may also be delivered by iontophoresis (see, for example, Pharmaceutical Research 3 (6):318 (1986)) and typically take the form of an optionally buffered aqueous solution of the active compound. In one embodiment, microneedle patches or devices are provided for delivery of drugs across or into biological tissue, particularly the skin. The microneedle patches or devices permit drug delivery at clinically relevant rates across or into skin or other tissue barriers, with minimal or no damage, pain, or irritation to the tissue.

Formulations suitable for administration to the lungs can be delivered by a wide range of passive, breath driven and active power driven single/multiple dose dry powder inhalers (DPI). The devices, most commonly used for respiratory delivery include nebulizers, metered-dose inhalers, and dry powder inhalers. Several types of nebulizers are available, including jet nebulizers, ultrasonic nebulizers, and vibrating mesh nebulizers. Selection of a suitable lung delivery device depends on parameters, such as nature of the drug and its formulation, the site of action, and pathophysiology of the lung.

Many methods and devices for drug delivery are known in the art. Non-limiting examples are described in the following patents and patent applications (fully incorporated herein by

Additional non-limiting examples of drug delivery devices and methods include, for example, US20090203709 titled “Pharmaceutical Dosage Form For Oral Administration Of Tyrosine Kinase Inhibitor” (Abbott Laboratories); US20050009910 titled “Delivery of an active
V. GENERAL SYNTHESIS

The compounds described herein can be prepared by methods known by those skilled in the art. In one non-limiting example the disclosed compounds can be made using the schemes below.

Compounds of the present invention with stereocenters may be drawn without stereoechemistry for convenience. One skilled in the art will recognize that pure enantiomers and diastereomers can be prepared by methods known in the art. Examples of methods to obtain optically active materials include at least the following.

i) physical separation of crystals—a technique whereby macroscopic crystals of the individual enantiomers are manually separated. This technique can be used if crystals of the separate enantiomers exist, i.e., the material is a conglomerate, and the crystals are visually distinct;

ii) simultaneous crystallization—a technique whereby the individual enantiomers are separately crystallized from a solution of the racemate, possible only if the latter is a conglomerate in the solid state;

iii) enzymatic resolutions—a technique whereby partial or complete separation of a racemate by virtue of differing rates of reaction for the enantiomers with an enzyme;

iv) enzymatic asymmetric synthesis—a synthetic technique whereby at least one step of the synthesis uses an enzymatic reaction to obtain an enantiomerically pure or enriched synthetic precursor of the desired enantiomer;

v) chemical asymmetric synthesis—a synthetic technique whereby the desired enantiomer is synthesized from an achiral precursor under conditions that produce asymmetry (i.e., chirality) in the product, which may be achieved using chiral catalysts or chiral auxiliaries;

vi) diastereomer separations—a technique whereby a racemic compound is reacted with an enantiomerically pure reagent (the chiral auxiliary) that converts the individual enantiomers to diastereomers. The resulting diastereomers are then separated by chromatography or
crystallization by virtue of their now more distinct structural differences and the chiral auxiliary later removed to obtain the desired enantiomer;

vii) first- and second-order asymmetric transformations—a technique whereby diastereomers from the racemate equilibrate to yield a preponderance in solution of the diastereomer from the desired enantiomer or where preferential crystallization of the diastereomer from the desired enantiomer perturbs the equilibrium such that eventually in principle all the material is converted to the crystalline diastereomer from the desired enantiomer. The desired enantiomer is then released from the diastereomer;

viii) kinetic resolutions—this technique refers to the achievement of partial or complete resolution of a racemate (or of a further resolution of a partially resolved compound) by virtue of unequal reaction rates of the enantiomers with a chiral, non-racemic reagent or catalyst under kinetic conditions;

ix) enantiospecific synthesis from non-racemic precursors—a synthetic technique whereby the desired enantiomer is obtained from non-chiral starting materials and where the stereochemical integrity is not or is only minimally compromised over the course of the synthesis;

x) chiral liquid chromatography—a technique whereby the enantiomers of a racemate are separated in a liquid mobile phase by virtue of their differing interactions with a stationary phase (including via chiral HPLC). The stationary phase can be made of chiral material or the mobile phase can contain an additional chiral material to provoke the differing interactions;

xi) chiral gas chromatography—a technique whereby the racemate is volatilized and enantiomers are separated by virtue of their differing interactions in the gaseous mobile phase with a column containing a fixed non-racemic chiral adsorbent phase;

xii) extraction with chiral solvents—a technique whereby the enantiomers are separated by virtue of preferential dissolution of one enantiomer into a particular chiral solvent;
xiii) transport across chiral membranes—a technique whereby a racemate is placed in contact with a thin membrane barrier. The barrier typically separates two miscible fluids, one containing the racemate, and a driving force such as concentration or pressure differential causes preferential transport across the membrane barrier. Separation occurs as a result of the non-racemic chiral nature of the membrane that allows only one enantiomer of the racemate to pass through.

xiv) simulated moving bed chromatography, is used in one embodiment. A wide variety of chiral stationary phases are commercially available.

As shown in General Scheme 1 compounds for use in the present invention can be prepared by chemically combining a Degron and a Linker followed by subsequent addition of a Targeting Ligand. Similarly, in General Scheme 2 compounds for use in the present invention are prepared by chemically combing a Targeting Ligand and Linker first, followed by subsequent addition of a Degron. As illustrated in the above and following schemes, compounds for use in the present invention can readily be synthesized by one skilled in the art in a variety of methods and chemical reactions.
General Scheme 3:

In Step 1, a nucleophilic Degron displaces a leaving group on the Linker to make a Degron Linker fragment. In Step 2, the protecting group is removed by methods known in the art to free a nucleophilic site on the Linker. In Step 3, the nucleophilic Degron Linker fragment displaces a leaving group on the Targeting Ligand to form a compound for use in the present invention. In an alternative embodiment Step 1 and/or Step 2 is accomplished by a coupling reaction instead of a nucleophilic attack.

General Procedure:
To the mixture of 1-1 (100mg) and 1-2 (1.1 eq.) in DMF (2ml) were added EDC.HCl (2.5eq), HOBT (1.5eq), and this was followed by the addition of DIPEA (3eq). The reaction mixture was stirred at room temperature for 16 hours to produce 1-3. After completion, crude 1-3 was purified by preparative HPLC to afford 1-3.

General methods for prep HPLC purification:
Method-1
Preparative HPLC was conducted on Waters auto purification instrument equipped with a YMC-Actus Triart C18 (100 x 30mm, 5µ) column operating at ambient temperature and flow rate: of 30.0 ml/min. Mobile phase: A = 20mM NH4HCO3 in water, B=Acetonitrile; Gradient Profile: Mobile phase initial composition of 80% A and 20% B, then to 65% A and 35% B in 2 minutes, then to 25% A and 75% B in 12 minutes, then to 5% A and 95% B in 13 minutes. This was maintained up to 15 minutes for column washing and the solvent mixture was returned to the initial composition for 16 minutes and maintained until 18 minutes.

Method-2
Preparative HPLC was conducted on Waters auto purification instrument equipped with a YMC-Actus Triart C18 (250 x 20mm, 5µ) column operating at ambient temperature and flow rate: of 20.0 ml/min. Mobile phase: A = 10mM NH4OAc in water, B = Acetonitrile; Gradient Profile: Mobile phase initial composition of 70% A and 30% B, then to 45% A and 55% B in 3 minutes, then to 25% A and 75% B in 18 minutes, then to 5% A and 95% B in 19 minutes. This was maintained for up to 21 minutes for column washing and the solvent mixture was returned to the initial composition for 22 minutes and maintained until 25 minutes.

Method-3
Preparative HPLC was conducted on Waters auto purification instrument equipped with a YMC-Actus Triart C18 (250 x 20mm, 5µ) column operating at ambient temperature and flow rate: of 20.0 ml/min. Mobile phase: A = 0.1% Formic acid in water, B = Acetonitrile; Gradient Profile: Mobile phase initial composition of 80% A and 20% B, then to 70% A and 30% B in 3 minutes, then to 25% A and 75% B in 18 minutes, then to 5% A and 95% B in 19 minutes. This
was maintained for up to 21 minutes for column washing and the solvent mixture was returned to the initial composition for 22 minutes and maintained until 25 minutes.

**Preparation of 3-(Benzyl-methyl-amino)-piperidine-2,6-dione (Compound 1)**

A solution of 3-bromo-piperidine-2,6-dione (2-1) (6 g, 31.25 mmol) and benzyl-methylamine (2-2) (10 g, 78.125 mmol) in DMF (30 mL) was stirred at ambient temperature 16 hours. The reaction mixture was then concentrated under reduced pressure and the crude mixture was purified by column chromatography (silica, gradient: 0-25% EtOAc in hexane) to afford 3-(benzyl-methyl-amino)-piperidine-2,6-dione (Compound 1) (6 g, 83%) as a grey solid.

1H NMR (400 MHz, DMSO-d6) δ 10.63 (s, 1H), 7.32 (s, 4H), 7.23 (brs, 1H), 3.76 (s, 2H), 3.60 (dd, J = 11.74, 4.34 Hz, 1H), 2.63-2.51 (m, 1H), 2.46-2.41 (m, 1H), 2.13-2.03 (m, 1H), 1.95-1.91 (m, 1H); LC-MS: ES+ 233.2.

**Preparation of 3-Methylamino-piperidine-2,6-dione (2-3)**

An ethyl acetate solution (100 mL) of 3-(benzyl-methyl-amino)-piperidine-2,6-dione (Compound 1) (2.5 g, 10.763 mmol) in a Parr shaker vessel was degassed with argon for about 15 minutes, and this was followed by the addition of 10% Pd/C (700 mg). The reaction vessel was backfilled with hydrogen and reaction mixture was subjected to hydrogenolysis on a Parr
hydrogenator for 16 hours at 50 psi hydrogen pressure at ambient temperature. The reaction mixture was filtered through a bed of celite and washed with ethyl acetate. The combined filtrates were concentrated under reduced pressure to afford 3-methylamino-piperidine-2,6-dione (2-3) (1.5 g, 98%) as a grey solid.

Step 1: Preparation of Compound 106

2-Methoxy-4-nitro-benzoic acid (474.33 mg, 2.41 mmol) and 3-aminopiperidine-2,6-dione (330 mg, 2.00 mmol, HCl) mixed in DMF (5 mL) at 0°C, followed by HATU (991.06 mg, 2.61 mmol), and diisopropylethylamine (777.37 mg, 6.01 mmol, 1.05 mL). The reaction mixture was stirred at room temp for 2 hrs, from [15:34]. HPLC and MS indicate all starting materials were
consumed and product present as the main peak. Dilute with 15 mL EtOAc, isolate via filtration. The cake was washed by water 3 times (10 mL each). Obtain compound 106 as white solid N-(2,6-dioxo-3-piperidyl)-2-methoxy-4-nitro-benzamide (495 mg, 1.61 mmol, 80.35% yield).

$^3$H NMR (400 MHz, DMSO-$d_6$) δ 10.88 (s, 1H), 8.73 (d, $J = 7.8$ Hz, 1H), 8.02 – 7.80 (m, 2H), 4.76 (dt, $J = 11.5, 6.9$ Hz, 1H), 4.00 (s, 3H), 2.77 (ddd, $J = 24.3, 12.4, 6.5$ Hz, 1H), 2.54 (d, $J = 3.8$ Hz, 1H), 2.23 – 2.00 (m, 2H). LC MS: ES+ 308.2

**Step 2: Preparation of Compound 107**

Add N-(2,6-dioxo-3-piperidyl)-2-methoxy-4-nitro-benzamide (300 mg, 976.38 umol) and Palladium, 5% on activated carbon paste, 5R437 (2.08 mg, 19.53 umol) to 20 mL vial, followed by DMF (4 mL), then purge with nitrogen at room temp for 15 mins. Hydrogen/vacuum purge 3 times, then let reaction mixture stirred at room temp under hydrogen atmosphere. The final product was isolated after celite pad filtration and concentration to afford white foam 4-amino-N-(2,6-dioxo-3-piperidyl)-2-methoxy-benzamide (compound 107) $^3$H NMR (400 MHz, DMSO-$d_6$) δ 10.81 (s, 1H), 8.31 (d, $J = 6.9$ Hz, 1H), 7.63 (dd, $J = 8.5, 1.0$ Hz, 1H), 6.23 (d, $J = 1.9$ Hz, 1H), 4.66 (ddd, $J = 12.2, 6.6, 5.3$ Hz, 1H), 3.82 (s, 3H), 2.71 (m, 2H), 2.17 – 1.94 (m, 2H). **General Procedure:**

To the mixture of compound amine (100mg) in DCM (3ml) were added TEA (3eq) and sulfonyl chloride (1.1eq) under ice cold condition. The reaction mixture was stirred at RT for 16h. At completion, reaction mixture was evaporated and dissolved in DMF. Crude material was submitted for prep-HPLC purification.

General procedure – A

To a stirred solution of 2-1 (1.0 mmol) in DMF (3 mL) was added Anilines 9-1 (2.5 mmol). The resulting solution was heated at 80°C-100°C for 5-24 hours to produce 9-2. Reaction mixture was then cooled to room temperature and evaporated under reduced pressure. Crude reaction mass was purified by reverse phase preparative HPLC, following the methods as are given below, to afford pure 9-3.

General procedure – B

To a stirred solution of 2-1 (1.0 mmol) in Dioxane (3 mL) was added Anilines 9-1 (2.5 mmol). The resulting solution was heated at 70°C-100°C for 5-24 hours to produce 9-2. Reaction mixture was then cooled to room temperature and evaporated under reduced pressure. Crude reaction mass was purified by reverse phase preparative HPLC, following the methods as are given below, to afford pure 9-3.

General methods for prep HPLC purification:

Method 1

Preparative HPLC was done on Waters auto purification instrument. Column name: YMC-Actus.Triart C18 (250 x 20mm, 5µ) operating at ambient temperature and flow rate of 20.0 ml/min. Mobile phase: A = 10mM NH4OAc in water, B = Acetonitrile; Gradient Profile: Mobile phase: initial composition of 70% A and 30% B, then to 45% A and 55% B in 3 min., then to 25% A and 75% B in 18 min., then to 5% A and 95% B in 19 min., held this composition up to 21 min. for column washing, then returned to initial composition in 22 min. and held till 25 min.
Method 2

Preparative HPLC was done on Waters auto purification instrument. Column name: YMC-Actus Triart C18 (250 x 20mm, 5µ) operating at ambient temperature and flow rate of 20.0 ml/min. Mobile phase: A = 0.1% Formic acid in water, B = Acetonitrile; Gradient Profile: Mobile phase: initial composition of 80% A and 20% B, then to 70% A and 30% B in 3 min., then to 25% A and 75% B in 18 min., then to 5% A and 95% B in 19 min., held this composition up to 21 min. for column washing, then returned to initial composition in 22 min. and held till 25 min. Use of basic buffer (NH4HCO3) causes hydrolysis of the Glutarimide ring either during prep HPLC run or during post purification evaporation.

IX. SYNTHESIS OF REPRESENTATIVE DEGRONS OF FORMULA V

Illustrative Preparation of 4-amino-substituted 2-(2,6-dioxo-piperidin-3-yl)-isoindole-1,3-diones via SNAr:
Example 1:
Scheme 1:
General procedure:

A mixture of 1-1 (1 mmol) and 1-2 (1 mmol) in Dimethylacetamide was heated at 90°C in a sealed tube in presence of DIPEA (3 mmol). After complete consumption of 1-1 as evident from TLC, the reaction mixture was cooled, partitioned between ethyl acetate and water, combined organic extracts washed with brine, dried over sodium sulfate and concentrated under reduced pressure. Crude mass was purified by reverse phase preparative HPLC to afford the desired product 1-3 as a solid.

General methods for prep HPLC purification:

Method-1

Preparative HPLC was conducted on Waters auto purification instrument equipped with a YMC-Actus Triart C18 (100 x 30mm, 5µ) column operating at ambient temperature and a flow rate of 30.0 ml/min. Mobile phase: A = 20mM NH₄HCO₃ in water, B = Acetonitrile; Gradient Profile: Mobile phase initial composition of 80% A and 20% B, then to 65% A and 35% B in 2 minutes, then to 25% A and 75% B in 12 minutes, then to 5% A and 95% B in 13 minutes. This was maintained up to 15 minutes for column washing and the solvent mixture was returned to the initial composition for 16 minutes and maintained until 18 minutes.

Method-2

Preparative HPLC was conducted on Waters auto purification instrument equipped with a YMC-Actus Triart C18 (250 x 20mm, 5µ) column operating at ambient temperature and a flow rate of 20.0 ml/min. Mobile phase: A = 10mM NH₄OAc in water, B = Acetonitrile; Gradient Profile: Mobile phase initial composition of 70% A and 30% B, then to 45% A and 55% B in 3 minutes, then to 25% A and 75% B in 18 minutes, then to 5% A and 95% B in 19 minutes. This was maintained for up to 21 minutes for column washing and the solvent mixture was returned to the initial composition for 22 minutes and maintained until 25 minutes.

Method-3

Preparative HPLC was conducted on Waters auto purification instrument equipped with a YMC-Actus Triart C18 (250 x 20mm, 5µ) column operating at ambient temperature and a flow rate of 20.0 ml/min. Mobile phase: A = 0.1% Formic acid in water, B = Acetonitrile; Gradient
Profile: Mobile phase initial composition of 80% A and 20% B, then to 70% A and 30% B in 3 minutes, then to 25% A and 75% B in 18 minutes, then to 5% A and 95% B in 19 minutes. This was maintained for up to 21 minutes for column washing and the solvent mixture was returned to the initial composition for 22 minutes and maintained until 25 minutes.

Scheme 2: Illustrative Preparation of 4-amino-substituted 2-(2,6-dioxo-piperidin-3-yl)-isoindole-1,3-dione hydrochloride (de-Boc):

5 General procedure:

A solution of Boc-substituted-4-amino-substituted 2-(2,6-dioxo-piperidin-3-yl)-isoindole-1,3-dione in dioxane at 0°C was treated with 4M HCl in dioxane and resulting mixture allowed stir at room temperature. After complete consumption of starting material as evident from TLC & LCMS, the volatiles were stripped off, residue triturated with pentane/ether, dried and finally lyophilized to afford the target hydrochloride as a solid.

The following compounds were made according the procedure of Scheme 2:

Scheme 3: Synthesis of (2-(2,6-dioxopiperidin-3-yl)-1,3-dioisoindolin-4-yl)alanine (Compound 252)

Step 1: An oven dried pressure tube was charged with 2-(2,6-dioxopiperidin-3-yl)-4-fluoroisoindoline-1,3-dione 1-1 (3 g, 10.68 mmol), DL-Alanine tert-butyl ester hydrochloride (2.95 g, 16.30 mmol), diisopropylethylamine (9.25 mL, 54.34 mmol), NMP (30 mL) and the reaction mixture was heated at 100 °C for 16 h. The reaction mixture was cooled to room temperature and diluted with water. The resulting solid compound which was precipitated out was fileted and washed with water, petroleum ether, dried under vacuum to yield tert-butyl((2-(2,6-dioxopiperidin-3-yl)-1,3-dioisoindolin-4-yl)alaninate 3-1 (2.8 g) as yellow gummy solid.

Step 2:
To a solution of tert-butyl (2-(2,6-dioxopiperidin-3-yl)-1,3-dioxoisindolin-4-yl)alaninate (2.8 g, 6.98 mmol) in dichloromethane (20 mL) at 0 °C and the reaction mixture was stirred at room temperature for 1 h. The reaction mixture was concentrated under reduced pressure and the crude was purified by prep. HPLC purification to yield (2-(2,6-dioxopiperidin-3-yl)-1,3-dioxoisindolin-4-yl)alanine Compound 252 (700 mg) as pale yellow solid.

Example 8: Illustrative Preparation of 7-member Glutarimide

Scheme 24:

Step-1

To a mixture of 24-1 (150 mg, 780 µmol) and 24-2 (100 mg, 780 µmol) in Acetic acid (3 mL) taken was added Ammonium acetate (60.1 mg, 780 µmol) and refluxed for 2 hours. Water was then added to the reaction mixture and the compound was extracted with DCM. The organic phase was separated, dried over anhydrous sodium sulfate and evaporated in vacuo to obtain the crude which was purified by silica gel column to afford 24-3 as white solid. Yield-21%; LC/MS: ES+ 304.1.

Step-2:

A mixture of periodic acid (224 mg, 984 µmol) and chromium trioxide (3.27 mg, 32.8 µmol) in Acetonitrile (3.0 mL) was stirred at room temperature for 30 min. Then acetic anhydride (92.5 µL, 984 µmol) was added. The reaction mixture was cooled to 0°C and 24-3 (50 mg, 164 µmol) was added in one portion and the reaction mixture was further stirred for 30 min at room temperature. After completion of the reaction, ice-water (15–20 mL) was added and the mixture was extracted with ethyl acetate (3 × 50 mL). The combined organic layer was washed with saturated NaHCO₃ solution, saturated Na₂S₂O₃ solution, and finally with brine. The organic phase was dried over anhydrous sodium sulfate and the solvent was removed under reduced pressure. The crude product was filtered through silica gel column using ethyl acetate as eluent to obtain Compound 327 as white solid. Yield-40%; ¹H NMR (400 MHz, DMSO-dong) δ 10.86 (s, 1H), 8.34

Scheme 25:

Step 1: Preparation of 2-(4-methyl-2-oxopiperidin-3-yl)isoindoline-1,3-dione (25-3)

To a stirred solution of compound 25-1 (173 mg, 1170 µmol) in toluene (5.0 mL), compound 25-2 (150.0 mg, 1170 µmol) was added and the reaction mixture was heated at 120°C in a sealed tube for 12 h. After checking TLC (Rf-0.3 in 30% EtOAc-hexane) the reaction mixture was diluted with ethyl acetate, washed with water, organic part was separated and concentrated under reduced pressure. The crude compound 25-3 (100 mg, 388 µmol, 33%) was used for the next step without any further purification. LCMS: ES+ 259.0.

Step 2: Preparation of 2-(4-methyl-2,6-dioxopiperidin-3-yl)isoindoline-1,3-dione (Compound 328)
To stirred solution of H5IO6 (793 mg, 3480 µmol) and Cr2O3 (28.9 mg, 290 µmol) in acetonitrile (10.0 mL), acetic anhydride (0.1 mL) was added at room temperature. The reaction mixture was then stirred at same temperature for 30 min. To this reaction mixture compound 25-3 (150.0 mg, 580 µmol) was added at 0°C at a time. The reaction mixture was then stirred at this temperature for 1 h. TLC showed formation of new spot (Rf-0.6 in 70% ea-hex). The reaction mixture was diluted with ethyl acetate; organic part was washed with water, aqueous Na₂S₂O₃ solution and dried over Na₂SO₄. The product was purified by preparative HPLC to give: Compound 328 (40 mg, 147 µmol, 25%) as white solid. ¹H NMR (400 MHz, DMSO-d₆) δ 11.18 (s, 1H), 7.93 (dt, J = 8.8, 5.7, 3.2 Hz, 3H), 4.90 (d, J = 11.5 Hz, 1H), 2.80 – 2.61 (m, 4H), 0.92 (d, J = 5.9 Hz, 3H); LC MS: ES+ 273.1

To a solution of (S)-2-(4-(4-chlorophenyl)-2,3,9-trimethyl-6H-thieno[3,2-f][1,2,4]triazolo[4,3-a][1,4]diazepin-6-yl)acetic acid 50-1 (450 mg, 1.12 mmol) in DMF (2.80 mL)
was added 8-aminooctan-1-ol (244 mg, 1.68 mmol), Diisopropylethylamine (389 µL, 2.24 mmol) and HATU (509 mg, 1.34 mmol). The reaction was stirred for 24 h, at which time the reaction was concentrated and purified by isoc (24 g column 0-10% MeOH/DCM) to provide (S)-2-(4-(4-chlorophenyl)-2,3,9-trimethyl-6H-thieno[3,2-f][1,2,4]triazolo[4,3-a][1,4]diazepin-6-yl)-N-(3-hydroxypropyl)acetamide (400 mg, 67.6%). LCMS ES+ = 529.1

Synthesis of (S)-2-(4-(4-Chlorophenyl)-2,3,9-trimethyl-6H-thieno[3,2-f][1,2,4]triazolo[4,3-a][1,4]diazepin-6-yl)-N-(8-hydroxyoctyl)acetamide (50-3):

A 25 mL rbf was charged with (S)-2-(4-(4-chlorophenyl)-2,3,9-trimethyl-6H-thieno[3,2-f][1,2,4]triazolo[4,3-a][1,4]diazepin-6-yl)-N-(8-hydroxyoctyl)acetamide 50-2 (400 mg, 757 µmol) and dichloromethane (4 mL). Dess-Martin Periodinane (0.3 M in DCM, 3.02 mL, 908 µmol) was added and the reaction was stirred at rt for 1 h, then quenched with 0.5 mL isopropanol, sat’d sodium thiosulfate, and sat’d sodium bicarbonate. LCMS ES+ 527.3.

Example 11: CRBN-DDB1 Fluorescence Polarization (FP) Assay
Measuring compound ligand binding to CRBN-DDB1 was carried out using an established sensitive and quantitative in vitro fluorescence polarization (FP) based binding assay. (See, I.J. Enyedy et al, J. Med. Chem., 44: 313-4324 [2001]). Compounds were dispensed from serially diluted DMSO stock into black 384-well compatible fluorescence polarization plates using an Echo acoustic dispenser. Compound binding to CRBN-DDB1 was measured by displacement of either a (-)-Thalidomide- Alexa Fluor® or Pomalidomide-fluorescein conjugated probe dye. A 20µL mixture containing 400nM CRBN-DDB1 and 5nM probe dye in 50mM Hepes, pH 7.4, 200mM NaCl, 1% DMSO and 0.1% pluronic acid-127 acid was added to wells containing compound and incubated at room temperature for 60 min. Matching control wells excluding CRBN-DDB1 were used to correct for background fluorescence. Plates were read on an Envision plate reader with appropriate FP filter sets. The corrected S (perpendicular) and P (parallel) values were used to calculate fluorescence polarization (FP) with the following equation: FP = 1000*(S−G*P)/(S+G*P). The fractional amount of bound probe (FB) to CRBN-DDB1 as a function of compound concentration was fitted according to Wang; FEBS Letters 360, (1995), 111-114 to obtain fits for parameter offsets and binding constant (k_diss) of competitor compound.

Example 12: Cell Viability Analysis

RPMI 1640 medium and fetal bovine serum (FBS) were purchased from Gibco (Grand Island, NY, USA). CellTiter-Glo® 2.0 Assay was purchased from Promega (Madison, WI, USA). MOLT4.1 (WT) cell line was purchased from ATCC (Manassas, VA, USA) and MOLT4.2 (CRBN Knock Out) cell line was generated in house. Cell culture flasks and 384-well microplates were acquired from VWR (Radnor, PA, USA).

MOLT4.1 and MOLT4.2 cell viability was determined based on quantification of ATP using CellTiter-Glo® 2.0 luminescent Assay kit, which signals the presence of metabolically active cells. Briefly, MOLT4.1 and MOLT4.2 cells were seeded into 384-well plates at a cell density of 750 cells per well, the plates were kept at 37 °C with 5% CO2 overnight. On the following day, test compounds were added to the cells from a top concentration of 1 µM with 10 points, half log titration in duplicates. The cells treated in the absence of the test compound were the negative control and the cells treated in the absence of CellTiter-Glo® 2.0 were the positive control. At the same day of compound treatment, CellTiter-Glo® 2.0 was added to a plate with cells treated in the absence of the test compound to establish Cytostatic control value (C_y). Cells
treated with the test compound were incubated for 72 hr. CellTiter-Glo reagent was then added to the cells and Luminescence was acquired on EnVision™ Multilabel Reader (PerkinElmer, Santa Clara, CA, USA).

Example 13: HiBit Assay

Materials: DMEM no-phenol red medium and fetal bovine serum (FBS) were purchased from Gibco (Grand Island, NY, USA). Nano-Glo® HiBiT Lytic Assay System was purchased from Promega (Medison, WI, USA). 293T.29 (HiBiT-BRD4 BD1) cell line was generated in house, ectopically expressing BRD4 BD1 domain with HiBiT fusion tag. Cell culture flasks and 384-well microplates were acquired from VWR (Radnor, PA, USA).

BRD4 BD1 Degradation Analysis: BRD4 BD1 degradation was determined based on quantification of luminescent signal using Nano-Glo® HiBiT Lytic Assay kit. Test compounds were added to the 384-well plate from a top concentration of 1 µM with 11 points, half-log titration in quadruplicates. 293T.29 cells were added into 384-well plates at a cell density of 15000 cells per well. The plates were kept at 37 °C with 5% CO2 for 3 hours. The cells treated in the absence of the test compound were the negative control and the cells treated with 30nM of a known BRD4 degrader were the positive control. After 3-hour incubation, Nano-Glo® HiBiT Lytic Assay reagents were added to the cells. Luminescence was acquired on EnVision™ Multilabel Reader (PerkinElmer, Santa Clara, CA, USA).

INTERNATIONAL SEARCH REPORT

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.: because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☒ Claims Nos.: 4-9, 10A, 10B, 11-15 because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying additional fees, this Authority did not invite payment of additional fees.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
☐ No protest accompanied the payment of additional search fees.
