(57) L'invention porte sur un procédé de nettoyage et de passivation d'une surface en acier inoxydable consistant: (1) à mettre la surface en contact avec 15/45 ml/l d'une composition comprenant entre environ 15 et 50 % d'un constituant alcalin, entre environ 1 et 15 % d'un chélateur et environ 35 et 84 % d'eau; (2) à maintenir le contact de façon à déloger et éliminer les résidus de la surface; (3) à maintenir le contact pour complexer les ions fer libres libérés de la surface avec le chélateur pour former une couche mince d'oxyde sur la surface; et (4) à maintenir le contact pour précipiter les ions complexés dans une couche mince d'oxyde. La composition peut en outre comporter un tensioactif choisi parmi des tensioactifs anioniques, cationiques, non ioniques ou zwitterioniques de façon à améliorer les performances de nettoyage.

(57) The invention includes a method for cleaning and passivating a stainless steel surface comprising: 1) contacting the surface with 15-45 ml/liter of a composition comprising between about 15 and 50 % alkaline component, between about 1 to 15 % chelant, and between about 35 to 84 % water; 2) maintaining contact to dislodge and remove residue from the surface; 3) continuing contact to complex free iron ions liberated from the surface with the chelant to form an oxide film on the surface; and 4) continuing contact to precipitate the complexed ions into the oxide film. The compositions may further include a surfactant selected from the group consisting of anionic, cationic, nonionic and zwitterionic surfactants to enhance cleaning performance.

TITLE OF THE INVENTION

STAINLESS STEEL ALKALI TREATMENT

BACKGROUND OF THE INVENTION

5 The present invention relates to compositions and methods for cleaning and passivating stainless steel surfaces, such as gas flow equipment, pharmaceutical manufacturing equipment, and semiconductor processing equipment.

10 During the past fifteen years the requirements for cleanliness in semiconductor processing equipment have increased at least a hundred times. Semiconductor feature sizes have been cut in half in the past few years and packing densities have doubled or tripled in the same time period. It also appears that the rate of change is accelerating rather than holding at past rates. With these changes, the problems caused by
15 contamination in semiconductor processing become even more serious. Cleanliness is also important in the health and pharmaceutical industries, driven by the need to reduce the contamination of treatment processes.

 In the past, stainless steel equipment used in these processes have been cleaned almost universally by use of solvents. In addition to
20 the problems of atmospheric pollution and operator health hazards, solvents do not clean absolutely. They leave films and particle residuals. Ultrasonic cleaning may also drive particles into crevices in instrument parts, for a later release. Chlorofluorocarbon cleaning solvents sold under the trademark Freon are examples of known cleaning solvents as
25 well as 1,1,1-trichloroethane and methylene chloride.

 The lack of cleanliness of the components cleaned by conventional solvents, methods and apparatus is problematical where active ions and organic contamination such as organic films remain on the components. Active ions, e.g. metallic ions, can adversely affect the
30 process in which the equipment is to be used.

 Passivation of cleaned steel surfaces is important for preventing conditions such as flash rusting of cleaned wet steel.

 In the prior art, cleaned steel is often passivated by treating with an nitric acid solution to provide altered surface characteristics that

resist rusting. Dilute solutions of citric acid made alkaline with ammonia or with an amine have been used for passivation of cleaned steel surfaces. These same solutions also have been used in combination with sodium nitrite.

5 Water-soluble amines are sometimes added to latex or water-dispersed coatings for steel to reduce corrosion. Water-soluble amines also have been added to final rinses for cleaned steel, but always in combination with other materials (such as other alkaline chemicals, citric acid, sodium nitrite, etc., and as exemplified in United States
10 Patents 3,072,502; 3,154,438; 3,368,913; 3,519,458; and 4,045,253) and therefore these rinses have left insoluble residues on the steel surfaces that are detrimental to optimum performance of subsequently applied protective coatings.

15 In the prior art, cleaned steel is often passivated by treating with an alkaline sodium nitrite solution to provide altered surface characteristics that resist rusting. For unknown reasons, this method is sometimes ineffective for passivating cleaned steel.

Dilute solutions of citric acid made alkaline with ammonia or with an amine have been used for passivation of cleaned steel surfaces.
20 These same solutions also have been used in combination with sodium nitrite.

United States Patent 4,590,100 describes a process that allows previously cleaned steel to be passivated with a rinse of almost pure water, that is made slightly alkaline with an amine to inhibit
25 corrosion preparatory to application of non-aqueous protective coatings, such that any small amine residue remaining on the steel surface after drying of the water will itself evaporate and in such a manner that any remaining amine residue will be incorporated into the non-aqueous protective coating without leaving any water-soluble or ionic residue on
30 the surface of the steel.

United States Patents 5,252,363 and 5,321,061 describe aqueous organic resin-containing compositions which are useful for depositing coatings on freshly galvanized metals to protect the metals against white rust and provide a surface which is universally paintable.

- 3 -

The organic resin consists essentially of at least one water-dispersible or emulsifiable epoxy resin or a mixture of resins containing at least one water-dispersible or emulsifiable epoxy resin.

5 United States Patent 5,039,349 describes a method and apparatus for cleaning surfaces, such as semiconductor processing equipment and pharmaceutical processing equipment, to absolute or near-absolute cleanliness involving spraying jets of heated clearing solution so that it flows over and scrubs the surfaces to be cleaned, producing a rinse liquid. The rinse liquid is
10 filtered and recirculated over the surface to be cleaned.

It is a purpose of the present invention to provide alkali-based formulations which both clean and passivate stainless steel surfaces.

25

30

SUMMARY OF THE INVENTION

5 The invention is a method for treating stainless steel that both cleans and passivates the stainless steel surface. Specifically, the invention is a method for cleaning and passivating a stainless steel surface comprising:

- 10 1) contacting the surface with 15-48 ml/liter of a composition comprising between about 15 and 50% alkaline component, between about 1 to 15% chelant, and between about 35 to 84% water;
- 15 2) maintaining contact to dislodge and remove residue from the surface;
- 3) continuing contact to complex free iron ions liberated from the surface with the chelant to form an oxide film on the surface; and
- 20 4) continuing contact to precipitate the complexed ions into the oxide film.

25 The compositions may further include a surfactant selected from the group consisting of anionic, cationic, nonionic and zwitterionic surfactants to enhance cleaning performance.

DETAILED DESCRIPTION OF THE INVENTION

30 Compositions which are used for treating stainless steel according to the present invention include an alkaline component, a chelant, and water. The compositions treat the stainless steel surface by removing residue, formed on the stainless steel surface during use of the stainless steel surface (e.g., during pharmaceutical or semiconductor processing), from the surface, simultaneously complexing free iron ions liberated from the stainless steel surface with a chelant and forming an

-5-

oxide film on the stainless steel surface, and precipitating the complexed ions into the oxide film.

Compositions of the invention comprise between about 15 and 50% alkaline component, between about 1 to 15% chelant, and between about 35 to 84%
5 water. Unless otherwise indicated, all amounts are percentages are weight/weight.

The compositions may further include 1-15% surfactant selected from the group consisting of anionic, cationic, nonionic and zwitterionic surfactants to enhance cleaning performance. Examples of such surfactants include but are not limited to water-soluble salts or higher fatty acid monoglyceride monosulfates, such
10 as the sodium salt of the monosulfated monoglyceride of hydrogenated coconut oil fatty acids, higher alkyl sulfates such as sodium lauryl sulfate, alkyl aryl sulfonates such as sodium dodecyl benzene sulfonate, higher alkyl sulfoacetates, higher fatty acid esters of 1, 2 dihydroxy propane sulfonates, and the substantially saturated higher aliphatic acyl amides of lower aliphatic amino carboxylic acid compounds,
15 such as those having 12 to 16 carbons in the fatty acid, alkyl or acyl radicals, and the like. Examples of the last mentioned amides are N-lauroyl sarcosine, and the sodium, potassium, and ethanolamine salts of N-lauroyl, N-myristoyl, or N-palmitoyl sarcosine.

Additional examples are condensation products of ethylene oxide
20 with various reactive hydrogen-containing compounds reactive therewith having long hydrophobic chains (e.g. aliphatic chains of about 12 to 20 carbon atoms), which condensation products ("ethoxamers") contain hydrophilic polyoxyethylene moieties, such as condensation products of poly (ethylene oxide) with fatty acids, fatty alcohols, fatty amides, polyhydric alcohols (e.g. sorbitan monostearate) and
25 polypropyleneoxide (e.g. Pluronic™ materials).

Miranol JEM™, an amphocarboxylate surfactant available from Rhone-Poulenc, Cranbury, New Jersey, is a typically suitable surfactant.

Alkaline components suitable for the present invention are hydroxide salts including, but not limited to, sodium hydroxide,

-6-

potassium hydroxide, and quaternary ammonium hydroxide. Such quaternary ammonium hydroxides include, but are not limited to, unsubstituted alkyl quaternary ammonium hydroxides such as tetramethyl ammonium hydroxide, tetraethyl ammonium hydroxide, tetrapropyl ammonium hydroxide, tetrabutyl ammonium hydroxide, and unsubstituted alkyl and aryl substituted ammonium hydroxides, including trimethylphenyl ammonium hydroxide and tripropylphenyl ammonium hydroxide. Alkaline salts such as carbonate salts are not suitable for present invention.

Chelants especially suitable for the present invention include ethylenediaminetetraacetate, hydroxyacetic acid, hydroxylaminotetraacetate and citric acid. Sodium gluconate is suitable but less preferred than the especially suitable chelants. Chelants such as polyacrylic acid, and Miranol JEM are not suitable for the present invention.

Water suitable for the present invention can be distilled water, soft water or hard water. Very hard water (e.g. 500 ppm) is also suitable if the amount of chelant is sufficiently higher than that which sequesters the metal ions such as calcium and magnesium.

Optionally, compositions of the invention can include more than one alkaline component and more than one chelant.

The stainless steel surfaces are treated by diluting the composition described above (which includes an alkaline component, a chelant, and water) to a concentration of 15-45 ml/liter to form a dilute solution, contacting the solution with the stainless steel surface to dislodge and remove residue from the surface, continuing contact to complex free ion liberated from the surface with the chelant to form an oxide film on the surface, and precipitating the complexed ions into the oxide film.

A preferred method of the invention comprises:

1) contacting the surface with 22-38 ml/liter of a composition comprising between about 20 and 35% alkaline.

- 7 -

component, between about 2 and 8% chelant, and between about 57 and 78% water;

5 2) maintaining contact to dislodge and remove residue from the surface;

3) continuing contact to complex free iron ions liberated from the surface with the chelant to form an oxide film on the surface; and

10

4) continuing contact to precipitate the complexed ions into the oxide film.

15 One embodiment of the preferred method of the invention comprises:

1) contacting the surface with 22-38 ml/liter of a composition comprising between about 20 and 35% potassium hydroxide, between about 2 and 8% ethylenediaminetetraacetate, and between about 57 and 78% water;

20

2) maintaining contact to dislodge and remove residue from the surface;

25

3) continuing contact to complex free iron ions liberated from the surface with the chelant to form an oxide film on the surface; and

30

4) continuing contact to precipitate the complexed ions into the oxide film.

Another embodiment of the preferred method of the invention comprises:

- 5 1) contacting the surface with 22-38 ml/liter of a composition comprising between about 20 and 35% sodium hydroxide, between about 2 and 8% ethylenediaminetetraacetate, and between about 57 and 78% water;
- 10 2) maintaining contact to dislodge and remove residue from the surface;
- 3) continuing contact to complex free iron ions liberated from the surface with the chelant to form an oxide film on the surface; and
- 15 4) continuing contact to precipitate the complexed ions into the oxide film.

20 In one particular embodiment of the invention, materials such as pharmaceutical products present in stainless steel manufacturing vessels to be cleaned and passivated are removed from the vessel. While the bulk of the material to be removed readily flows from the stainless steel vessel, a residue film remains on the stainless steel surface.

25 Compositions used in the present invention are contacted with the film-coated surface in one or more of several ways. One way to contact the film-coated surface is by using a fixed spray-ball mechanism which showers the composition onto the film-coated surface such that all film-coated surfaces are contacted with the composition. Another way to contact the film-coated surface is by using a flexible spray-ball mechanism which, at various positions within the vessel, showers the composition onto the film-coated surface such that all film-coated surfaces are contacted with the composition. Another way is to fill the vessel such that all film-coated surfaces are contacted with the composition.

30

After contact is initiated, the film is dislodged and solubilized, dispersed, or emulsified into the composition and removed from the vessel. Free iron ions are liberated from the surface and form an oxide film on the surface. The
5 complexed ions of iron are precipitated into the oxide film. The composition removed from the vessel is optionally discarded or recycled.

Using the method of the invention, stainless steel can be cleaned and passivated in one treatment. The method provides a passive protective film in addition to cleaning stainless steel surfaces.

10 In Example 2 below, water alone, potassium hydroxide alone, and compositions including an alkaline component, a chelant, and water, were evaluated.

Table 2 in Example 2 represents data obtained from studies evaluating the passivation properties of compositions of the invention. Corrosion, measured electrochemically in mils per year (MPY), is initially high, but drops
15 significantly and remains low after a passive film is formed. Subsequent exposure of these passivated electrodes to fresh solutions of the same formulation results in no rise in corrosion rate, due to the protective effect of the passive film previously formed.

The passivation property is the result of chelation properties of
20 the chelant. As the corrosion reaction is initiated the free iron ions liberated are complexed by the chelant. An oxide film forms on the metal surface upon exposure to the alkaline component. The complexes readily precipitate and incorporate into the oxide film, enhancing the integrity of the oxide film.

-10-

Example 1 (control)

Stainless steel 316 (containing at least chromium, nickel and iron) electrodes were treated with a 34% nitric acid solution, a standard solution used for passivating stainless steel surfaces. A corrosion rate profile was generated by immersing the electrodes in a fresh diluted solution, and monitoring the corrosion rate, measured electrochemically, in mils per year. The profile showed initial corrosion for a short period of time, resulting in formation of a protective film, followed by an extended period of time showing virtually no additional corrosion.

Example 2

Compositions having the following formulation were prepared by adding potassium hydroxide to water, followed by addition of chelant, either ethylenediaminetetraacetate (EDTA), sodium gluconate, polyacrylic acid, or Miranol JEM™:

Table 1
Formulation

	<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>
<u>Ingredient</u>				
KOH (45%)	46%	46%	46%	46%
EDTA (39%)	10	—	—	—

Total	100%	100%	100%	100%

- 11 -

Each formulation was evaluated by diluting to a concentration of 31 ml/liter, immersing stainless steel 316 electrodes with the diluted formulation at 80°C, and monitoring the corrosion rate, as measured in mils per year. Water alone and potassium hydroxide alone were also evaluated. Table 2 shows the corrosion rate achieved using Formulations 1, 2, 3 or 4 described in Table 1, KOH (20%), or water.

Table 2
Corrosion rate

	<u>1</u>	<u>2</u>	<u>3</u>	<u>4</u>	<u>KOH (20%)</u>	<u>water</u>

6 hours	0.1	0.07	0.07	0.07	-	-

25

The data demonstrate that exposure of stainless steel to a formulation of potassium hydroxide along with ethylenediamine-tetraacetate results in an initial corrosive effect, which results in a formation of a passive film, followed by a reduced rate of corrosion over time.

30

Example 3

Cleaning and passivating a pharmaceutical fermentation vessel

5 Pharmaceutical product present in a stainless steel
pharmaceutical fermentation vessel to be cleaned and passivated is
removed from the vessel. After the bulk of product is removed, a residue
film remains on the stainless steel surface. A diluted (31 ml/liter)
composition of 46% KOH (45%), 10% EDTA (39%), and 44% water is
10 sprayed onto the film-coated surface. The film is dislodged dispersed
into the composition and removed from the vessel. Free iron ions are
liberated from the surface and form an oxide film on the surface. The
complexed ions of iron are precipitated into the oxide film. The
composition removed from the vessel is optionally discarded or recycled.

15 Within the first 20-30 minutes of contact between the film-
coated surface and the alkaline composition, a passive protective oxide
film forms on the surface.

20 Using the method of the invention, stainless steel can be
cleaned and passivated in one treatment. The method provides a passive
protective film in addition to cleaning stainless steel surfaces.

-13-

**THE EMBODIMENTS OF THE INVENTION IN WHICH AN EXCLUSIVE
PROPERTY OR PRIVILEGE IS CLAIMED ARE DEFINED AS FOLLOWS:**

1. A method for cleaning and passivating a chromium containing
5 stainless steel surface comprising:
 - 1) contacting the surface with 15-45 ml/liter of a composition
comprising between about 15 and 50% by weight of alkaline component effective
to clean and passivate stainless steel, between about 1 to 15% by weight of chelant
effective to clean and passivate stainless steel and between about 35 to 84% by
10 weight water;
 - 2) maintaining said contact to dislodge and remove residue from the
surface;
 - 3) continuing said contact to complex free iron ions liberated from
the surface with the chelant to form an oxide film on the surface; and
 - 15 4) continuing said contact to precipitate the complexed ions into the
oxide film.
2. A method of claim 1 comprising:
 - 1) contacting the surface with 22-38 ml/liter of a composition
20 comprising between about 20 and 35% by weight of alkaline component, between
about 2 and 8% by weight chelant, and between about 57 and 78% by weight water;
 - 2) maintaining contact to dislodge and remove residue from the
surface;
 - 3) continuing contact to complex free iron ions liberated from the
25 surface with the chelant to form said oxide film on the surface; and
 - 4) continuing contact to precipitate the complexed ions into the oxide
film.
3. A method of claim 2 comprising:
 - 1) contacting the surface with 22-38 ml/liter of a composition
30 comprising between about 20 and 35% by weight potassium hydroxide, between

-14-

about 2 and 8% by weight ethylenediaminetetraacetate, and between about 57 and 78% by weight water;

2) maintaining contact to dislodge and remove residue from the surface;

5 3) continuing contact to complex free iron ions liberated from the surface with the chelant to form said oxide film on the surface; and

4) continuing contact to precipitate the complexed ions into the oxide film.

10 4. A method of claim 2 comprising:

1) contacting the surface with 22-38 ml/liter of a composition comprising between about 20 and 35% by weight sodium hydroxide, between about 2 and 8% by weight ethylenediaminetetraacetate, and between about 57 and 78% by weight water;

15 2) maintaining contact to dislodge and remove residue from the surface;

3) continuing contact to complex free iron ions liberated from the surface with the chelant to form said oxide film on the surface; and

20 4) continuing contact to precipitate the complexed ions into the oxide film.

5. A method of claim 1 wherein the composition comprises 1 - 15% surfactant selected from the group consisting of anionic, cationic, nonionic, and zwitterionic surfactants.

25

6. A method for removing residue from and passivating a chromium containing stainless steel surface, the method comprising:

1) contacting the surface with a composition which consists essentially of between about 15 and 50% by weight of an alkaline component said alkaline component being a hydroxide selected from the group consisting of
30 potassium hydroxide and sodium hydroxide, between about 1 and 15% by weight

-15-

of a chelant and between about 39 and 84% by weight of water diluted with water to a concentration of 15-45 ml/liter;

2) maintaining said contacting to dislodge and remove iron ion and chromium ion residue from said surface; and

5 3) continuing said contacting to provide on said surface a substantially transparent passivating film comprising a portion of said iron ions and said chromium ions in oxidized form and a portion of said iron and chromium ions complexed with said chelant;

10 whereby a clean surface which is substantially passive to further oxidation is provided.

7. A method for removing residue from and passivating a chromium containing stainless steel surface, the method comprising:

15 1) contacting the stainless steel surface with a composition which consists essentially of:

 a) between about 20 and 35% by weight of an alkaline component said alkaline component being a hydroxide selected from the group consisting of potassium hydroxide and sodium hydroxide;

20 b) between 2 and 8% by weight of a chelant; and
 c) between about 57 and 78% by weight of water, diluted with water to a concentration of 22 to 38 ml/liter,

 2) maintaining said contacting to dislodge and remove at least iron ions, chromium ions, and said residue from said surface; and

25 3) continuing said contacting to provide on said surface a substantially transparent passivating film including at least chromium and iron ions in oxidized form at least partially complexed with said chelant;

 whereby a clean surface which is substantially passive to further oxidation is provided.

-16-

8. A method for removing residue from and passivating a chromium containing stainless steel surface, the stainless steel including at least iron, chromium and nickel, the method comprising:

5 1) contacting the surface with a composition consisting essentially of between about 15 and 50% by weight of an alkaline component, said alkaline component being a hydroxide selected from the group consisting of potassium hydroxide and sodium hydroxide, between about 1 and 15% by weight of ethylenediaminetetraacetate as a chelant and between about 39 and 84% by weight of water, diluted with water to a concentration of 15 to 45 ml/liter;

10 2) maintaining said contacting to dislodge and remove said residue from said surface and to oxidize iron, chromium, and nickel at the surface; and

3) continuing said contacting to provide on said surface a substantially transparent passivating film including oxides of at least chromium, iron, and nickel complexed with the ethylenediaminetetraacetate;

15 whereby a clean surface which is substantially passive to further oxidation is provided.

9. The method of claim 7 wherein the chelant is ethylenediaminetetraacetate.

20

10. The method of claim 6 wherein said composition includes between about 1% and 15% by weight of a surfactant selected from the group consisting of anionic, cationic, nonionic and zwitterionic surfactants.
