A b s t r a c t

The invention relates to heterocyclamide-substituted imidazoles and methods for their preparation, their use for the treatment and/or prophylaxis of diseases as well as their use for the production of medicaments for the treatment and/or prophylaxis of diseases, in particular for the use as antiviral agents, especially against cytomegaloviruses.

### Heterocyclamide-substituted imidazoles

The invention relates to heterocyclamide-substituted imidazoles and methods for their preparation, their use for the treatment and/or prophylaxis of diseases as well as their use for the production of medicaments for the treatment and/or prophylaxis of diseases, in particular for use as antiviral agents, especially against cytomegaloviruses.

WO 99/23091 describes aromatic heterocyclic compounds as antiinflammatory agents which, inter alia, may also be suitable for the treatment of viral infections.

Structurally different agents having antiviral activity are available on the market; however, the therapies currently available with ganciclovir, valganciclovir, foscarnet and cidofovir are associated with severe side effects, for example nephrotoxicity, neutropenia or thrombocytopenia. In addition, it is always possible for resistance to develop. Novel agents for an effective therapy are therefore desirable.

One object of the present invention is therefore to provide novel compounds having the same or improved antiviral activity for the treatment of viral infectious diseases in humans and animals.

It has been surprisingly found that the substituted imidazoles described in the present invention have high antiviral activity.

The present invention furthermore relates to the use of the compounds of the invention for the production of a medicament for the treatment and/or prophylaxis of diseases, in particular the diseases mentioned above.

The present invention furthermore relates to a method for the treatment and/or prophylaxis of diseases, in particular the diseases mentioned above, using an antivirally effective amount of the compounds of the invention.

ily, nasally, sublingually, lingually, buccally, rectally, dermally, transdermally, conjunctivally or otically, or as an implant or stent.

For these administration routes, it is possible to administer the compounds of the invention in suitable administration forms.

Suitable for oral administration are administration forms which function according to the prior art and release the compounds of the invention rapidly and/or in modified form, and which comprise the compounds of the invention in crystalline and/or amorphized and/or dissolved form, such as, for example, tablets (uncoated and coated tablets, for example having enteric coatings or coatings which dissolve with a delay or which are insoluble and which control the release of the compound of the invention), tablets or films/wafers, which disintegrate rapidly in the oral cavity, films/lyophilisates, capsules (for example hard or soft gelatin capsules), sugar-coated tablets, granules, pellets, powders, emulsions, suspensions, aerosols or solutions.

Parenteral administration can take place with avoidance of an absorption step (for example intravenously, intraarterially, intracardially, intraspinally or intralumbally) or with inclusion of an absorption (for example intramuscularly, subcutaneously, intracutaneously, percutaneously or intraperitoneally). Administration forms suitable for parenteral administration are, inter alia, preparations for injection and infusion in the form of solutions, suspensions, emulsions, lyophilisates or sterile powders.

Examples suitable for the other administration routes are pharmaceutical forms for inhalation (inter alia powder inhalers, nebulizers), nasal drops, solutions, sprays; tablets, films/wafers or capsules, to be administered lingually, sublingually or buccally, suppositories, preparations for ears or eyes, vaginal capsules, aqueous suspensions (lotions, shaking mixtures), lipophilic suspensions, ointments, creams, transdermal therapeutic systems, milk, pastes, foams, dusting powders, implants or stents.

The compounds of the invention can be converted into the stated administration forms. This can take place in a manner known per se by mixing with inert nontoxic, pharmaceutically acceptable excipients. These excipients include, inter alia, carriers (for example microcrystalline cellulose, lactose, mannitol), solvents (for example liquid polyethylene glycols), emulsifiers and dispersants or wetting agents (for example sodium dodecyl sulfate, polyoxysorbitan oleate), binders (for example polyvinylpyrrolidone), synthetic and natural polymers (for example albumin), stabilizers (for example antioxidants, such as, for example, ascorbic acid), colors (for example inorganic pigments, such as, for example, iron oxides) and taste- and/or odor-correctors.

The present invention furthermore relates to medicaments comprising at least one compound of the invention, usually together with one or more inert nontoxic, pharmaceutically acceptable excipients, and their use for the purposes mentioned above.

In general, it has proved advantageous to administer on intravenous administration amounts of about 0.001 to 10 mg/kg, preferably about 0.01 to 5 mg/kg, of body weight to achieve effective results, and the dosage on oral administration is about 0.01 to 25 mg/kg, preferably 0.1 to 10 mg/kg, of body weight.

It may nevertheless be necessary, where appropriate, to deviate from the amounts mentioned, specifically depending on body weight, administration route, individual response to the active compound, type of preparation and time or interval over which the administration takes place. Thus, in some cases it may be sufficient to make do with less than the aforementioned minimum amount, whereas in other cases the upper limit mentioned must be exceeded. In the event of an administration of larger amounts, it may be advisable to divide these into a plurality of individual doses over the day.

The percentage data in the following tests and examples are percentages by weight unless otherwise indicated; parts are parts by weight. Solvent ratios, dilution ratios and concentration data of liquid/liquid solutions are in each case based on volume.

**Starting compounds****Example 1A**

Ethyl 1-benzyl-1H-imidazole-2-carboxylate

148 g (936 mmol) of 1-benzyl-1H-imidazole are suspended in 480 ml of acetonitrile and, at -20°C, 120 ml (87.1 g; 860 mmol) of triethylamine are added. Over a period of 15 minutes, 211.2 ml (239 g; 2208 mmol) of ethyl chloroformate are then added dropwise. The reaction mixture is stirred at -20°C for 10 minutes. After warming to 15 to 20°C, the reaction mixture is stirred for 18 h and then concentrated in vacuo. Water, a saturated sodium chloride solution and a saturated sodium bicarbonate solution are added to the residue, and the mixture is extracted three times with ethyl acetate. The combined organic phases are washed with a saturated sodium chloride solution and, after drying with magnesium sulfate, concentrated in vacuo. The residue is subjected to a fractional distillation under high vacuum (boiling point = 173 to 181°C, pressure = 1.7 to 1.2 mbar).

**Example 52**

N-(3,5-Difluorophenyl)-N'-{1-ethyl-2-[(4-pyridin-2-yl)piperazin-1-yl]carbonyl]-1H-imidazol-4-yl}urea

Firstly, a spatula tip of Raney nickel and then 11 mg (0.23 mmol) of hydrazine hydrate are added to a solution of 50 mg (0.15 mmol) of 1-[(1-ethyl-4-nitro-1H-imidazol-2-yl)carbonyl]-4-(pyridin-2-yl)piperazine in 6 ml of absolute THF, and the mixture is then stirred for 1 h. Sodium sulfate is added to the crude solution, which is then filtered through kieselguhr, and the filtercake is washed with methylene chloride. The filtrate is concentrated in vacuo and taken up again in 6 ml of THF, 28 mg (0.18 mmol) of difluorophenyl isocyanate and 2 mg of 1,4-diazabicyclo[2.2.2]octane are added and the mixture is stirred at room temperature. After 1 h, the solvent is removed on a rotary evaporator and the residue is purified by preparative HPLC. 20 mg (29% of theory) of product are obtained.

**B. Assessment of the physiological activity**

The *in vitro* activity of the compounds of the invention can be shown in the following assays:

**Anti-HCMV (anti-human cytomegalovirus) cytopathogenicity tests**

The test compounds are employed as 50 millimolar (mM) solutions in dimethyl sulfoxide (DMSO). Ganciclovir, foscarnet and cidofovir are used as reference compounds. After the addition of in each case 2  $\mu$ l of the 50, 5, 0.5 and 0.05 mM DMSO stock solutions to 98  $\mu$ l portions of cell culture medium in row 2 A-H for duplicate determinations, 1:2 dilutions are carried out with 50  $\mu$ l portions of medium up to row 11 of the 96-well plate. The wells in rows 1 and 12 each contain 50  $\mu$ l of medium. Then 150  $\mu$ l of a suspension of  $1 \times 10^4$  cells (human prepuce fibroblasts [NHDF]) are pipetted into each of the wells (row 1 = cell control) and, in rows 2-12, a mixture of HCMV-infected and uninfected NHDF cells (M.O.I. = 0.001 – 0.002), i.e. 1-2 infected cells per 1000 uninfected cells. Row 12 (without substance) serves as virus control. The final test concentrations are 250-0.0005  $\mu$ M. The plates are incubated at 37°C/5% CO<sub>2</sub> for 6 days, i.e. until all the cells in the virus controls are infected (100% cytopathogenic effect [CPE]). The wells are then fixed and stained by adding a mixture of formalin and Giemsa's dye (30 minutes), washed with double-distilled water and dried in a drying oven at 50°C. The plates are then assessed visually using an overhead microscope (Plaque Multiplier from Technomara).

The following data can be acquired from the test plates:

CC<sub>50</sub> (NHDF) = maximum substance concentration in  $\mu$ M at which no visible cytostatic effects on the cells are evident by comparison with the untreated cell control;

EC<sub>50</sub> (HCMV) = substance concentration in  $\mu$ M which inhibits the CPE (cytopathic effect) by 50% compared with the untreated virus control;

SI (selectivity index) = CC<sub>50</sub> (NHDF) / EC<sub>50</sub> (HCMV).

Representative *in vitro* activity data of the compounds of the invention are shown in Table A:

**Table A**

The suitability of the compounds of the invention for the treatment of HCMV infections can be shown in the following animal model:

#### **HCMV Xenograft Gelfoam® model**

##### **Animals:**

3-4-week old female immunodeficient mice (16-18 g), Fox Chase SCID or Fox Chase SCID-NOD or SCID beige, are purchased from commercial breeders (Bomholtgaard, Jackson). The animals are kept under sterile conditions (including bedding and feed) in isolators.

##### **Virus growing:**

Human cytomegalovirus (HCMV), Davis strain, is grown *in vitro* on human embryonic prepuce fibroblasts (NHDF cells). After the NHDF cells have been infected with a multiplicity of infection (M.O.I.) of 0.01, the virus-infected cells are harvested 5-7 days later and stored in the presence of minimal essential medium (MEM), 10% foetal calf serum (FCS) with 10% DMSO at -40°C. After serial ten-fold dilutions of the virus-infected cells, the titre is determined on 24-well plates of confluent NHDF cells after vital staining with Neutral Red, or fixing and staining with a formalin/Giemsa mixture (as described above).

##### **Preparation of the sponges, transplantation, treatment and evaluation:**

Collagen sponges 1×1×1 cm in size (Gelfoam®; Peasel & Lorey, order No. 407534; K.T. Chong et al., Abstracts of 39th Interscience Conference on Antimicrobial Agents and Chemotherapy, 1999, p. 439; P.M. Kraemer et al., Cancer Research 1983, (43): 4822-

4827) are initially wetted with phosphate-buffered saline (PBS), the trapped air bubbles are removed by degassing, and then stored in MEM + 10% FCS.  $1 \times 10^6$  virus-infected NHDF cells (infection with HCMV Davis M.O.I. = 0.01) are detached 3 hours after the infection and added dropwise in 20  $\mu$ l of MEM, 10% of FCS, onto a moist sponge. After 12-13 hours 5 ng/ $\mu$ l basic fibroblast growth factor (bFGF) in 25  $\mu$ l of PBS /0.1% BSA/1 mM DTT are optionally added to the sponges and the sponges are incubated for 1 hour. For the transplantation, the immunodeficient mice are anaesthetized with avertin or a mixture of azepromazine-xylazine and ketamine, the fur on the back is removed using a dry shaver, the epidermis is opened 1-2 cm, unstressed and the moist sponges are transplanted under the dorsal skin. The surgical wound is closed with tissue glue. 24 hours after the transplantation, the mice are treated with substance perorally three times a day (7.00 h and 14.00 h and 19.00 h), two times a day (8.00 h and 17.00 h) or once a day (14.00 h) over a period of 8 days. The dose is 3 or 10 or 30 or 100 mg/kg of body weight, the volume administered is 10 ml/kg of body weight. The substances are formulated in the form of a 0.5% Tylose suspension, optionally containing 2% DMSO. 9 days after the transplantation and 16 hours after the last administration of substance, the animals are painlessly sacrificed and the sponge is removed. The virus-infected cells are released from the sponge by collagenase digestion (330 U/1.5 ml) and stored in the presence of MEM, 10% foetal calf serum, 10% DMSO at -140°C. Evaluation takes place after serial ten-fold dilutions of the virus-infected cells by determining the titre on 24-well plates of confluent NHDF cells after vital staining with Neutral Red or after fixing and staining with a formalin/Giemsa mixture (as described above). The number of infectious virus particles after the substance treatment compared with the placebo-treated control group is determined.
