Abstract: Electrolyte compositions containing a solvent mixture comprising 2,2-difluoroethyl acetate and ethylene carbonate are described. The electrolyte compositions are useful in electrochemical cells, such as lithium ion batteries.
Title
FLUORINATED ELECTROLYTE COMPOSITIONS

This application claims priority under 35 U.S.C. §119(e) from, and claims the benefit of, U.S. Provisional Application No. 61/530,545, filed 02 September 2011, which is by this reference incorporated in its entirety as a part hereof for all purposes.

Technical Field

The disclosure hereof relates to electrolyte compositions containing 2,2,-difluoroethyl acetate and ethylene carbonate, which are useful in electrochemical cells, such as lithium ion batteries.

Background

Carbonate compounds are currently used as electrolyte solvents for non-aqueous batteries containing electrodes made from alkali metals, alkaline earth metals, or compounds comprising these metals, for example lithium ion batteries. Current lithium ion battery electrolyte solvents typically contain one or more linear carbonates, such as ethyl methyl carbonate, dimethyl carbonate, or diethylcarbonate; and a cyclic carbonate, such as ethylene carbonate. However, at battery voltages above 4.4 V these electrolyte solvents can decompose, which can result in a loss of battery performance. Additionally, there
are safety concerns with the use of these electrolyte solvents because of their low boiling point and high flammability.

To overcome the limitations of commonly used non-aqueous electrolyte solvents, various fluorine-containing carboxylic acid ester electrolyte solvents have been investigated for use in lithium ion batteries (see, for example, Nakamura et al in JP 4/328,915-B2, JP 3/444,607-B2, and U.S. Patent No. 8,097,368). Although these fluorine-containing carboxylic acid ester electrolyte solvents can be used in lithium ion batteries having high voltage cathodes, such as the 4.7 V LiMn$_1$_3Ni$_0$_3O$_4$ cathode, cycling performance can be limited, particularly at high temperatures.

Despite the efforts in the art as described above, a need remains for electrolyte solvents, and compositions thereof, that will have improved cycling performance at high temperature when used in a lithium ion battery, particularly such a battery that operates at high voltage (i.e. up to about 5 V), or that incorporates a high voltage cathode.

Summary

In one embodiment, there is provided herein an electrolyte composition comprising:

(a) at least one electrolyte salt; and

(b) a solvent mixture comprising ethylene carbonate
and CH$_3$CO$_2$CH$_2$CF$_3$H.

In another embodiment, there is provided herein an electrolyte composition comprising:
5 (a) at least one electrolyte salt; and
(b) a solvent mixture comprising ethylene carbonate at a concentration of about 10% to about 50% by weight of the solvent mixture; and CH$_3$CO$_2$CH$_2$CF$_3$H at a concentration of about 50% to about 90% by weight of the solvent mixture.

In yet another embodiment, there is provided herein an electrochemical cell comprising the electrolyte composition disclosed herein.

In a further embodiment, the electrochemical cell is a lithium ion battery.

**Brief Description of the Drawings**

Figures 1-3 are voltage vs. capacity curves for the first charge and discharge cycles for full cells containing the electrolyte compositions disclosed herein, as described in Examples 5-6 and Comparative Example 2, respectively.

**Detailed Description**

As used above and throughout the description of the invention, the following terms, unless otherwise indicated, shall be defined as follows:
The term "electrolyte composition" as used herein, refers to a chemical composition suitable for use as an electrolyte in an electrochemical cell. An electrolyte composition typically comprises at least one solvent and at least one electrolyte salt.

The term "electrolyte salt" as used herein, refers to an ionic salt that is at least partially soluble in the solvent of the electrolyte composition and that at least partially dissociates into ions in the solvent of the electrolyte composition to form a conductive electrolyte composition.

The term "anode" refers to the electrode of an electrochemical cell, at which oxidation occurs. In a galvanic cell, such as a battery, the anode is the negatively charged electrode. In a secondary (i.e. rechargeable) battery, the anode is the electrode at which oxidation occurs during discharging and reduction occurs during charging.

The term "cathode" refers to the electrode of an electrochemical cell, at which reduction occurs. In a galvanic cell, such as a battery, the cathode is the positively charged electrode. In a secondary (i.e. rechargeable) battery, the cathode is the electrode at which reduction occurs during discharging and oxidation occurs during charging.
The term "lithium ion battery" refers to a type of rechargeable battery in which lithium ions move from the anode to the cathode during discharge, and from the cathode to the anode during charge.

Disclosed herein are electrolyte compositions comprising a fluorine-containing carboxylic acid ester and ethylene carbonate. The electrolyte compositions are useful in electrochemical cells, particularly lithium ion batteries. Specifically, the electrolyte compositions disclosed herein comprise at least one electrolyte salt, and a solvent mixture comprising CH₃CO₂CH₂CF₃H (2,2,-difluoroethyl acetate, CAS No. 1550-44-3), and ethylene carbonate (also referred to as 1,3-dioxolan-2-one, CAS No. 96-49-1).

In one embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture. In another embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture. In another embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture. In another embodiment, ethylene carbonate comprises about 30% by weight of the solvent mixture.

In an alternative embodiment, 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture. In another embodiment, 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture. In another embodiment,
2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture. In another embodiment, 2,2,-difluoroethyl acetate comprises about 70% by weight of the solvent mixture.

Ethylene carbonate of suitable purity for use in the electrolyte compositions disclosed herein may be obtained from commercial sources such as Novolyte (Independence, OH). The 2,2,-difluoroethyl acetate may be prepared using methods known in the art. For example, acetyl chloride may be reacted with 2,2-difluoroethanol (with or without a basic catalyst) to form 2,2-difluoroethyl acetate. Additionally, 2,2-difluoroethyl acetate may be prepared using the method described by Wiesenhofer et al. (WO 2009/040367 A1, Example 5). Alternatively, 2,2-difluoroethyl acetate can be prepared using the method described in the examples herein below. It is desirable to purify the 2,2-difluoroethyl acetate to a purity level of at least about 99.9%, more particularly at least about 99.99%. The 2,2-difluoroethyl acetate may be purified using distillation methods such as vacuum distillation or spinning band distillation.

The electrolyte compositions disclosed herein also contain at least one electrolyte salt. Suitable electrolyte salts include without limitation lithium hexafluorophosphate, Li PF$_3$(CF$_2$CF$_3$)$_3$, lithium bis(trifluoromethanesulfonyl)imide, lithium bis (perfluoroethanesulfonyl)imide,
lithium (fluorosulfonyl) 
nonafluorobutanesulfonyl)imide, 
lithium bis(fluorosulfonyl)imide, 
lithium tetrafluoroborate, 
lithium perchlorate, 
lithium hexafluoroarsenate, 
lithium trifluoromethanesulfonate, 
lithium tris (trifluoromethanesulfonyl)methide, 
lithium bis(oxalato)borate, 
lithium difluoro(oxalato)borate, 
Li$_2$B$_{12}$F$_{12}$-$\times$H$_x$ where x is equal to 0 to 8, and mixtures of lithium fluoride and anion receptors such as B(OC$_6$F$_5$)$_3$.

Mixtures of two or more of these or comparable electrolyte salts may also be used. In one embodiment, the electrolyte salt is lithium hexafluorophosphate. The electrolyte salt can be present in the electrolyte composition in an amount of about 0.2 to about 2.0 M, more particularly about 0.3 to about 1.5 M, more particularly about 0.5 to about 1.2 M, and more particularly about 1.0 to about 1.2 M.

The electrolyte composition disclosed herein may further comprise at least one additional co-solvent. Examples of suitable co-solvents include without limitation one or more carbonates. Suitable carbonates include ethyl methyl carbonate, dimethyl carbonate, diethyl carbonate, propylene carbonate, vinylethylene carbonate, fluoroethylene carbonate, 2,2,2-trifluoroethyl carbonate, 2,2,2-trifluoroethyl
carbonate, and methyl 2,2,3,3-tetrafluoropropyl carbonate. In other embodiments, suitable co-solvents include without limitation those selected from the group consisting of ethyl methyl carbonate, dimethyl carbonate, diethyl carbonate, propylene carbonate, vinylethylene carbonate, 2,2,2-trifluoroethyl carbonate, and methyl 2,2,3,3-tetrafluoropropyl carbonate. It is desirable to use a co-solvent that is battery grade or has a purity level of at least about 99.9%, and more particularly at least about 99.99%. When an additional co-solvent is used, the co-solvent comprises about 10% to about 40% by weight, or about 15% to about 35% by weight, or about 20% to about 30% by weight, of the solvent mixture.

When fluoroethylene carbonate (also referred to herein as 4-fluoro-1,3-dioxolan-2-one, CAS No. 114435-02-8) is used as the co-solvent, it can if desired be used in an amount of about 0.01% to less than 2%, more particularly about 0.1% to about 1.8%, more particularly about 0.5% to about 1.5%, and more particularly about 1% by weight of the total electrolyte composition. It is desirable to purify the fluoroethylene carbonate to a purity level of at least about 99.0%, more particularly at least about 99.9%. Purification may be done using known methods, as described above. Fluoroethylene carbonate is available from companies such as China LangChem INC. (Shanghai, China) and MTI Corp. (Richmond, CA).

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of
the solvent mixture; and 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture.

5 In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; and 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture.

10 In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; and 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture.

15 In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; and a co-solvent comprises about 10% to about 40% by weight of the solvent mixture.

20 In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; and a co-solvent comprises about 15% to about 35% by weight of the solvent mixture.

25
In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; and a co-solvent comprises about 20% to about 30% by weight of the solvent mixture.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to less than 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.
In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; and a co-solvent comprises about 10% to about 40% by weight of the solvent mixture.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; and a co-solvent comprises about 15% to about 35% by weight of the solvent mixture.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; and a co-solvent comprises about 20% to about 30% by weight of the solvent mixture.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.
In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to less than 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; and a co-solvent comprises about 10% to about 40% by weight of the solvent mixture.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; and a co-solvent comprises about 15% to about 35% by weight of the solvent mixture.
In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; and a co-solvent comprises about 20% to about 30% by weight of the solvent mixture.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to less than 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.
In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of
the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of
the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

5 In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 10% to about 50% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 50% to about 90% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.
In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2-trifluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of
the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture;
the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

5 In a further alternative embodiment, ethylene carbonate comprises about 20% to about 40% by weight of the solvent mixture; 2,2,2,-difluoroethyl acetate comprises about 60% to about 80% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

- 19 -
In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 10% to about 40% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of
the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 15% to about 35% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.01% to less than 2% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.1% to about 1.8% by weight of the total electrolyte composition.

In a further alternative embodiment, ethylene carbonate comprises about 25% to about 35% by weight of the solvent mixture; 2,2,2-difluoroethyl acetate comprises about 65% to about 75% by weight of the solvent mixture; a co-solvent comprises about 20% to about 30% by weight of
the solvent mixture; and fluoroethylene carbonate comprises an amount of about 0.5% to about 1.5% by weight of the total electrolyte composition.

In another embodiment, the invention provides an electrochemical cell comprising a housing, an anode and a cathode disposed in the housing and in conductive contact with one another, an electrolyte composition, as described above, providing an ionically conductive pathway between the anode and the cathode, and a porous separator between the anode and the cathode. The housing may be any suitable container to house the electrochemical cell components. The anode and the cathode may be comprised of any suitable conducting material depending on the type of electrochemical cell. Suitable examples of anode materials include without limitation lithium metal, lithium metal alloys, lithium titanate, aluminum, platinum, palladium, graphite, transition metal oxides, and lithiated tin oxide. Suitable examples of cathode materials include without limitation graphite, aluminum, platinum, palladium, electroactive transition metal oxides comprising lithium, indium tin oxide, and conducting polymers such as polypyrrole and polyvinylferrocene.

The porous separator serves to prevent short circuiting between the anode and the cathode. The porous separator typically consists of a single-ply or multi-ply sheet of a microporous polymer such as polyethylene, polypropylene, or a combination thereof. The separator may also be a polyimide nanoweb (EP 2037029; U.S. Patent...
Application No. 2011/0143217 A1). The pore size of the porous separator is sufficiently large to permit transport of ions, but small enough to prevent contact of the anode and cathode either directly or from particle penetration or dendrites which can form on the anode and cathode.

In another embodiment, the electrochemical cell is a lithium ion battery. Suitable cathode materials for a lithium ion battery include without limitation electroactive transition metal oxides comprising lithium, such as LiCoO$_2$, LiNiO$_2$, LiMn$_2$O$_4$ or LiV$_2$O$_5$; oxides of layered structure such as LiNi$_x$Mn$_y$Co$_{2-x-y}$O$_2$ where $x+y+z$ is about 1, LiCo$_{0.2}$Ni$_{0.2}$O$_2$, LiFePO$_4$, LiMnPPO$_4$, LiCoPO$_4$, LiNi$_{0.5}$Mn$_{1.5}$O$_4$, or LiVPO$_4$F; mixed metal oxides of cobalt, manganese, and nickel such as those described in U.S. Patent No. 6,964,828 (Lu) and U.S. Patent No. 7,078,128 (Lu); nanocomposite cathode compositions such as those described in U.S. Patent No. 6,680,145 (Obrovac); lithium-rich layered-layered composite cathodes such as those described in U.S. Patent No. 7,468,223; and cathodes such as those described in U.S. Patent No. 7,718,319 and the references therein (each of the above mentioned U.S. patents being by this reference incorporated in its entirety as a part hereof for all purposes).

In another embodiment, the cathode in the lithium ion battery hereof comprises a cathode active material exhibiting greater than 30 mAh/g capacity in the potential range greater than 4.6 V versus lithium metal. One
example of such a cathode is a manganese cathode comprising a lithium-containing manganese composite oxide having a spinel structure as cathode active material. The lithium-containing manganese composite oxide in a cathode suitable for use herein comprises oxides of the formula

\[ \text{Li}_x \text{Mn}_{1.5} \text{Ni}_x \text{M}_y \text{O}_{4-d}, \]  
(Formula I)

wherein M is at least one metal selected from the group consisting of Al, Cr, Fe, Ga, Zn, Co, Nb, Mo, Ti, Zr, Mg, V and Cu, \( 0.38 \leq x < 0.5, \quad 0 < y \leq 0.12, \quad 0 \leq d \leq 0.3, \) and \( 0.00 < z \leq 1.1, \) and z changes in accordance with release and uptake of lithium ions and electrons during charge and discharge.

In one embodiment, M in the above formula is Fe; in another embodiment, M in the above formula is Ga; and in another embodiment, M is the above formula is Fe and Ga.

In the various embodiments hereof, the values of x and y can be selected from any one of the members of the group of couples consisting of: \( x=0.38/y=0.12, \ x=0.39/y=0.11, \ x=0.40/y=0.1, \ x=0.41/y=0.09, \ x=0.42/y=0.08, \ x=0.43/y=0.07, \ x=0.44/y=0.06, \ x=0.45/y=0.05, \ x=0.46/y=0.04, \ x=0.47/y=0.03, \ x=0.48/y=0.02, \ x=0.49/y=0.01.

In one embodiment, z has a value given by \( 0.03 \leq z \leq 1.1. \) In another embodiment, z has a value given by \( 0.03 \leq z \leq 1.0. \) In one embodiment, M in the above formula is
at least one metal selected from the group consisting of
Al, Cr, Fe, Ga and Zn, \(0.4 \leq x < 0.5, \quad 0 < y \leq 0.1,\)
z = 1 and d = 0.

The lithium cathode material described above is
believed to be stabilized by the presence of the M
component in the compound. Manganese cathodes stabilized
by other systems may also comprise spinel-layered
composites which contain a manganese-containing spinel
component and a lithium rich layered structure, as
described in U.S. Patent No. 7,303,840.

A cathode active material suitable for use herein can
be prepared using methods such as the hydroxide precursor
method described by Liu et al (J. Phys. Chem. C 13:15073-
15079, 2009). In that method, hydroxide precursors are
precipitated from a solution containing the required
amounts of manganese, nickel and other desired metal(s)
acetates by the addition of KOH. The resulting
precipitate is oven-dried and then fired with the required
amount of LiOH·H₂O at about 800 to about 950°C in oxygen
for 3 to 24 hours, as described in detail in the examples
herein. Alternatively, the cathode active material can
be prepared using a solid phase reaction process or a sol-
gel process as described in U.S. Patent No. 5,738,957
(Amine).

A cathode, in which the cathode active material is
contained, suitable for use herein may be prepared by
methods such as mixing an effective amount of the cathode
active material (e.g. about 70 wt% to about 97 wt%), a polymer binder, such as polyvinylidene difluoride, and conductive carbon in a suitable solvent, such as N-methylpyrrolidone, to generate a paste, which is then coated onto a current collector such as aluminum foil, and dried to form the cathode.

A lithium ion battery as disclosed herein can further contain an anode, which comprises an anode active material that is capable of storing and releasing lithium ions. Examples of suitable anode active materials include without limitation lithium alloys such as lithium-aluminum alloy, lithium-lead alloy, lithium-silicon alloy, lithium-tin alloy and the like; carbon materials such as graphite and mesocarbon microbeads (MCM); phosphorus-containing materials such as black phosphorus, MnP₃ and CoP₃; metal oxides such as SnO₂, SnO and TiO₂; and lithium titanates such as Li₄Ti₅O₁₂ and LiTi₂O₄. In one embodiment, the anode active material is lithium titanate or graphite.

An anode can be made by a method similar to that described above for a cathode wherein, for example, a binder such as a vinyl fluoride-based copolymer is dissolved or dispersed in an organic solvent or water, which is then mixed with the active, conductive material to obtain a paste. The paste is coated onto a metal foil, preferably aluminum or copper foil, to be used as the current collector. The paste is dried, preferably with heat, so that the active mass is bonded to the
current collector. Suitable anode active materials and anodes are available commercially from companies such as NEI Inc. (Somerset NJ), and Farasis Energy Inc. (Hayward CA).

A lithium ion battery as disclosed herein also contains a porous separator between the anode and cathode. The porous separator serves to prevent short circuiting between the anode and the cathode. The porous separator typically consists of a single-ply or multi-ply sheet of a microporous polymer such as polyethylene, polypropylene, polyamide or polyimide, or a combination thereof. The pore size of the porous separator is sufficiently large to permit transport of ions to provide ionically conductive contact between the anode and cathode, but small enough to prevent contact of the anode and cathode either directly or from particle penetration or dendrites which can from on the anode and cathode. Examples of porous separators suitable for use herein are disclosed in U.S. Application SN 12/963,927 (filed 09 Dec 2010), which is by this reference incorporated in its entirety as a part hereof for all purposes.

The housing of the lithium ion battery hereof may be any suitable container to house the lithium ion battery components described above. Such a container may be fabricated in the shape of small or large cylinder, a prismatic case or a pouch.
The lithium ion battery hereof may be used for grid storage or as a power source in various electronically-powered or -assisted devices ("Electronic Device") such as a transportation device (including a motor vehicle, automobile, truck, bus or airplane), a computer, a telecommunications device, a camera, a radio or a power tool.
Examples

The subject matter disclosed herein is further defined in the following examples. It should be understood that these examples, while describing various features of certain particular embodiments of some of the inventions hereof, are given by way of illustration only.

The meaning of abbreviations used is as follows: "cm" means centimeter(s), "mm" means millimeter(s), "μm" means micrometer(s), "g" means gram(s), "mg" means milligram(s), "kg" means kilogram(s), "μg" means microgram(s), "L" means liter(s), "mL" means milliliter(s), "μL" means microliter(s), "mol" means mole(s), "mmol" means millimole(s), "M" means molar concentration, "h" means hour(s), "min" means minute(s), "s" means second(s), "wt%" means percent by weight, "Hz" means hertz, "mS" means millisiemen(s), "mA" mean milliamp(s), "mAh means milliamp hour(s), "mAh/g" means milliamp hour(s) per gram, "mAh/cm²" means milliamp hour(s) per cm², "V" means volt(s), "dc" means direct current, "x C" refers to a constant current that can fully charge/discharge the cathode in 1/x hours, "kPa" means kilopascal(s), "rpm" means revolutions per minute, "psi" means pounds per square inch.
Materials and Methods

Purification of 2,2-Difluoroethyl Acetate (DFEA)

2,2-Difluoroethyl acetate, obtained from Matrix Scientific (Columbia, SC), was purified by spinning band distillation twice to 99.99% purity, as determined by gas chromatography using a flame ionization detector.

Preparation of LiMn$_{1.8}$Ni$_{0.42}$Fe$_{0.08}$O$_4$ (Fe-LNMO) Cathode Active Material

For the preparation of LiMn$_{1.8}$Ni$_{0.42}$Fe$_{0.08}$O$_4$, 401 g manganese (II) acetate tetrahydrate (Aldrich, No. 63537), 121 g nickel (II) acetate tetrahydrate (measured to have 4.8 water of hydration) (Aldrich, No. 72225) and 15.25 g iron (II) acetate anhydrous (Alfa Aesar, Ward Hill, MA, No. 31140) were weighed into bottles on a balance then dissolved in 5.0 L of deionized water. KOH pellets were dissolved in 10 L of deionized water to produce a 3.0 M solution inside a 30 L reactor. The acetate solution was transferred to an addition funnel and dripped into the rapidly stirred reactor to precipitate the mixed hydroxide material. Once all 5.0 L of the acetate solution was added to the reactor, stirring was continued for 1 h.

Then, stirring was stopped and the precipitate was allowed to settle overnight. After settling the liquid was removed from the reactor and 15 L of fresh deionized water was added. The contents of the reactor were stirred, allowed to settle again, and the liquid was removed. This rinse process was repeated. Then, the precipitate was
transferred to two (split evenly) coarse glass frit filtration funnels covered with Dacron® paper. The solids were rinsed with deionized water until the filtrate pH reached 6 (i.e., the pH of deionized rinse water), and a further 20 L of deionized water was added to each filter cake. Finally the cakes were dried in a vacuum oven at 120 °C overnight. The yield at this point was typically 80-90%.

The hydroxide precipitate was next ground and mixed with lithium carbonate. This step was done in 50 g batches using a Pulverisette automated mortar and pestle (Fritsch GmbH, Idar-Oberstein, Germany). For each batch the hydroxide mixture was weighed, then ground alone for 5 min in the Pulveresette. Then, a stoichiometric amount with small excess of lithium carbonate was added to the system. For 50 g of hydroxide 10.5 g of lithium carbonate was added. Grinding was continued for a total of 60 min with stops every 10-15 min to scrape the material off the surfaces of the mortar and pestle with a sharp metal spatula. If humidity caused the material to form clumps, it was sieved through a 40 mesh screen once during grinding, then again following grinding.

The ground material was fired in an air box furnace inside shallow rectangular alumina trays. The trays were 158 mm by 69 mm in size, and each held about 60 g of material. The firing procedure consisted of ramping from room temperature to 900 °C in 15 h, holding at 900 °C for 12 h, then cooling to room temperature in 15 h.
Preparation of an Iron-Doped, Lithium, Nickel, Manganese Oxide (Fe-LNMO) Cathode

A cathode paste was prepared from: 3.12 g Fe-LNMO (prepared as described above), 0.390 g carbon black (acetylene black, uncompressed, Denka Corp., New York, NY), 3.24 g of polyvinylidene difluoride (PVDF) solution, 12% in N-methylpyrrolidone (NMP) (KFL #1120, Kureha America Corp., New York, NY) and of 6.17 g NMP. The Fe-LNMO was ground using a mortar and pestle and sifted through a 400 mesh sieve. The carbon black, 5.82 g of NMP, and the PVDF solution were combined in a plastic vial and mixed using a planetary centrifugal mixer (THINKY ARE-310, THINKY Corp., Japan) for 1 min at 2000 rpm. The vial was removed from the mixer, allowed to briefly cool, and the mixing was repeated two more times for a total of three times. The Fe-LNMO and 0.35 g of NMP were then added and centrifugally mixed three times for 1 min at 2000 rpm each time. The vial was mounted in an ice bath and homogenized twice using a rotor-stator (model PT 10-35 GT, 7.5 mm diameter stator, Kinematica, Bohemia, NY) for 15 min each at 6500 rpm and then twice more for 15 min at 9500 rpm.

The paste was cast using a 50 mm wide doctor blade with a 0.19 mm gate height onto untreated aluminum foil. The electrode was dried in a mechanical convection oven (model FDL-115, Binder Inc., Great River, NY) for 15 min at 100 °C. The loading of Fe-LNMO was about 3 mg/cm². The
resulting 50-mm wide electrode was placed between 250 μm thick brass sheets and passed through a calender using 102 mm diameter steel rolls at ambient temperature with a nip force of 330 kg. The electrode was further dried in a vacuum oven at 90°C at -25 inches of Hg (-85 kPa) for 15 h.

Preparation of a Lithium Titanate (LTO) Anode

The following were used to make the anode paste: 4.16 g Li₄Ti₅O₁₂ (LTO, Nanomyte™ BE-10, NEI Corporation, Somerset, NJ), 4.00 g PVDF solution, 12% in NMP (KFL #1120, Kureha America Corp.), 0.52 g carbon black (acetylene black, uncompressed, Denka Corp., New York, NY), and 9.50 g NMP. The carbon black, PVDF solution, and 8.04 g of the NMP were first combined in a plastic vial and centrifugally mixed (THINKY ARE-310, THINKY Corp., Japan) for 60 s at 2000 rpm. The vial was removed from the mixer, allowed to briefly cool, and the mixing was repeated two more times for a total of three times. The LTO powder, along with the additional NMP, were added to the carbon black and PVDF mixture, and the paste was centrifugally mixed three times for 60 s each time. The vial was mounted in an ice bath and homogenized twice using a rotor-stator (model PT 10-35 GT, 7.5 mm diameter stator, Kinematica, Bohemia, NY) for 15 min each at 6500 rpm and then twice more for 15 min at 9500 rpm. The paste was cast using a 50 mm wide doctor blade with a 0.25 mm gate height onto untreated aluminum foil. The electrode was dried in a mechanical convection oven (model FDL-115,
Binder Inc., Great River, NY) for 15 min at 100 °C. After removal of NMP, the anode consisted of 80:10:10 LTO:PVDF:Carbon Black. The loading of LTO was about 4 mg/cm². The resulting 50-mm wide electrode was placed between 250 µm thick brass sheets and passed through a calender using 102 mm diameter steel rolls at ambient temperature with a nip force of 250 kg. The electrode was further dried in a vacuum oven at 90 °C at -25 inches of Hg (-85 kPa) for 15 h.

Fabrication of LiMn₁.₅Ni₀.₄₂Fe₀.₈₀O₄/Li₄Ti₅O₁₂ Full Cells

A LiMn₁.₅Ni₀.₄₂Fe₀.₈₀O₄ cathode, prepared as described above, a Celgard® separator 2325 (Celgard, LLC. Charlotte, NC), a Li₄Ti₅O₁₂ anode, prepared as described above, and a few drops of the electrolyte composition of interest, as described below, were sandwiched in 2032 stainless steel coin cell cans to form the LiMn₁.₅Ni₀.₄₂Fe₀.₈₀O₄/Li₄Ti₅O₁₂ full cells.

Circular pieces of the separator were cut with a 5/8 inch arch punch and the pieces were transferred to a glovebox. Circular sections of LiMn₁.₅Ni₀.₄₂Fe₀.₈₀O₄ cathodes were cut with a 1/2 inch arch punch. The cells were cathode limited; that is, the anode loading was high enough such that a circular area of the same size could incorporate more lithium than could be released by the cathode based on conversion of Li₄Ti₅O₁₂ to Li₇Ti₅O₁₂.
Circular sections of the Li$_4$Ti$_5$O$_{12}$ anodes were cut with a 9/16 inch arch punch. The pre-cut cathode and anode sections were heated to 90 °C for 12 h under vacuum in an antechamber, and then transferred to a glovebox.

The coin cells consisted of coin cell cases (SUS316L), spacer disks, wave springs, and caps, and a polypropylene gasket, all obtained from Hohsen Corp. (Osaka, Japan). The coin cell components were sonicated in ultra-high purity water with detergent for one hour, rinsed with ultra-high purity water for 60 min, and then dried at 90 °C under house vacuum. The cleaned coin cell components were transferred to a glovebox.

A spacer disk and a gasket were placed in the coin cell case and 90 μL of the electrolyte composition to be tested, as described below, was added. A circular separator was then placed on the wetted cathode. An additional 90 μL of electrolyte was added onto the separator. The circular anode section was placed on top of the separator. The spacer disk was set on the anode and all layers were aligned in the center of the coin cell case. The wave spring was set on top of the spacer disk and aligned. The cap was set on top of the wave spring and manually pushed into the gasket. The assembly was placed in an automated coin cell battery crimper (Hohsen Corp. Model SAHCC-2032, Osaka, Japan) and pressure was applied to seal the coin cell.
COMPARATIVE EXAMPLE 1 AND WORKING EXAMPLES 1-3

Preparation of Electrolyte Compositions

These Examples describe the preparation of electrolyte compositions containing lithium hexafluorophosphate salt and solvent mixtures comprising 2,2-difluoroethyl acetate (DFEA) and ethylene carbonate (EC); 2,2-difluoroethyl acetate and fluoroethylene carbonate (FEC); and 2,2-difluoroethyl acetate, ethylene carbonate and a small amount of fluoroethylene carbonate.

Electrolyte compositions containing DFEA, EC and 1.0 M LiPF₆; and DFEA, FEC and 1.0 M LiPF₆ were prepared by weighing predetermined amounts of the components into vials in a dry box. The lithium hexafluorophosphate (LiPF₆) (battery grade, Stella Chemifa Corp., Tokyo, Japan) was weighed into each vial to give a final concentration of 1.0 M. Then, the first electrolyte solvent (DFEA, prepared as described above) and the second electrolyte solvent (EC, battery grade, obtained from Novolyte Corp. Cleveland, OH; or FEC, obtained from LongChem, Shanghai, China, and purified by vacuum distillation) were weighed into each vial to give the desired weight percent (wt%) of each component. An electrolyte composition containing DFEA, EC, 1.0 M LiPF₆, and 1% FEC was prepared by weighing a predetermined amount of FEC and adding it to a predetermined amount of the electrolyte composition containing DFEA, EC and 1.0 M LiPF₆. The components of the electrolyte compositions are summarized in Table 1.

EXAMPLE 4

**Ionic Conductivity of Electrolyte Compositions**

The electrical conductivity of the electrolyte compositions described in Comparative Example 1 and Working Examples 1-3 was measured using ac impedance spectroscopy over the frequency range of 0.1 to 1,000,000 Hz. The impedance results were fit with an equivalent circuit model to yield the dc resistance.
An electrical probe containing two wires was first calibrated over the conductivity range of 10 to 100,000 Hz using standard aqueous solutions of sodium chloride. Then, the electrical probe was placed in the electrolyte compositions to be measured. Ionic conductivity measurements were recorded at temperatures of 22 to 25 °C in a dry box. Results were extrapolated to 25 °C using the temperature dependence of 2.0%/°C. The results summarized in Table 2 are reported at 25 °C.

Electrolytes with high ionic conductivity are desired since low conductivity decreases battery performance at high rates of charging and discharging. Replacing the 20 wt% FEC in Comparative Example 1 with EC while maintaining the LiPF$_6$ salt molarity constant (Example 1) increases the conductivity from 6.98 to 7.65 mS/cm. The conductivity can be further increased to 8.08 mS/cm by changing the ratio of the two solvents from 80:20 DFEA:EC to 70:30 DFEA:EC (Example 2). Adding 1% FEC to the 70:30 DFEA:EC
and 1.0 M LiPF₆ composition (Example 3) reduced the conductivity slightly to 7.83 mS/cm.

**WORKING EXAMPLES 5-6, AND COMPARATIVE EXAMPLE 2**

**Formation Processing (Slow Cycling) of LiMn₁₋₅Ni₀.₃₂Fe₀.₈₂O₄/Li₆Ti₅O₁₂ Full Cells**

Lithium ion batteries are often cycled before use at a slow rate for one or more cycles, a process that is referred to as “formation”. Each coin cell, prepared as described above, was first charged at 0.1 C from its open circuit voltage to 3.4 V at room temperature using a commercial battery tester (Series 4000, Maccor, Tulsa, OK). This was followed by discharging each cell at 0.1 C from 3.4 V to 1.9 V. The 0.1 C charge and discharge were then repeated a second time between 1.9 and 3.4 V. Results for the formation process are compiled in Figures 1-3 and Table 3.

The three coin cells had similar first cycle charge capacities, with the small differences attributed to variations in the cathode loadings. The first cycle discharge capacity was much lower for the 80:20 DFEA:FEC and 1.0 M LiPF₆ electrolyte composition (Comparative Example 2) than for the 70:30 DFEA:EC and 1.0 M LiPF₆ electrolyte composition (Example 5) and the 70:30 DFEA:EC, 1.0 M LiPF₆ and 1% FEC electrolyte composition (Example 6).

Although the general shape of the voltage vs. capacity curves was similar for charging all three cells
(Figures 1-3), there was a notable difference in the discharge curves. Both the 70:30 DFEA:EC and 1.0 M LiPF<sub>6</sub> electrolyte composition (Example 5, Figure 1) and the 70:30 DFEA:EC, 1.0 M LiPF<sub>6</sub> and 1% FEC electrolyte composition (Example 6, Figure 2) yielded discharge curves in which the tail end of the capacity contained a shoulder at the 2.5 V plateau, which was also present during the charging process. This shoulder was not present for the 80:20 DFEA:FEC and 1.0 M LiPF<sub>6</sub> electrolyte composition (Comparative Example 2, Figure 3) due to the reduced first cycle discharge capacity for this inferior electrolyte. The reduced first cycle discharge capacity also corresponds to a loss in capacity for further cycling. This is demonstrated by the lower second cycle charge and discharge capacities for the cell containing 80:20 DFEA:FEC and 1.0 M LiPF<sub>6</sub> electrolyte composition (Comparative Example 2) compared to the cells containing the other two electrolyte compositions (Examples 5 and 6), as shown in Table 3.

WORKING EXAMPLES 7-8, AND COMPARATIVE EXAMPLE 3

Cycling of LiMn$_{1.5}$Ni$_{0.42}$Fe$_{0.08}$O$_4$/Li$_4$Ti$_5$O$_{12}$ Full Cells at Elevated Temperature

Following the two-cycle formation process at room temperature, each cell was cycled in a commercial battery tester (Series 4000, Maccor, Tulsa, OK) at 55 °C between 1.9 V and 3.4 V using a cycling protocol in which the cell was cycled at constant current at C/2 for 29 cycles followed by a single cycle at constant current at C/5. This (29 X C/2 + 1 X C/5) cycling procedure was repeated 10 times, for a total of 300 charge-discharge cycles. As a part of the cycling protocol, the impedance at 1000 Hz was measured following the completion of each charge step and the completion of each discharge step. Results are shown in Table 4.

</table>
The electrolyte composition containing 70:30 DFEA:EC and 1.0 M LiPF$_6$ retained 44.4% of its initial capacity after 299 cycles at 55 °C (Example 7 in Table 4). After the first 50 cycles, the Coulombic efficiency stayed above 99% for the remaining cycles at C/2 and was 99.5% for the 299th cycle.

The electrolyte composition containing 70:30 DFEA:EC, 1.0 M LiPF$_6$ and 1% FEC retained 38.0% capacity after 299 cycles at 55 °C (Example 8 in Table 4). The Coulombic efficiency was 98.7% at the 50th cycle and stayed above this value for the remaining cycles at C/2, reaching a value of 98.9% at the 299th cycle.

The electrolyte composition containing 80:20 DFEA:FEC and 1.0 M LiPF$_6$ performed poorly in comparison to the other two electrolyte compositions that contained EC (Comparative Example 3 in Table 4). The capacity dropped quickly during the early stages of cycling, dropping below 50% by the 25th cycle. The capacity retention for the 299th cycle was 7.8%. The Coulombic efficiency was poor, never exceeding 96% for the cycles at C/2 and dropping to 93.0% by the 299th cycle.

In various embodiments of the lithium ion battery hereof, pairs of dopant metals and fluorinated solvent systems may be formed from (i) any one or more of all of the members of the total group of dopant metals disclosed herein (Al, Cr, Fe, Ga, Zn, Co, Nb, Mo, Ti, Zr, Mg, V and
Cu), selected as described above as a single member or any subgroup of any size taken from the total group of doping metals in all the various different combinations of individual members of that total group, together with (ii) any one or more of all of the members of the total group of the fluorinated solvent systems disclosed herein, selected as described above as a single member or any subgroup of any size taken from the total group of those fluorinated solvent systems in all the various different combinations of individual members of that total group.

Subgroups of the members of the groups of dopant metals or fluorinated solvents may be formed by omitting any one or more members from the respective whole groups as set forth above. As a result, the dopant metal or fluorinated solvent system (or pair thereof) may not only be the members of any subgroup of any size that may be formed from the whole group from all the various different combinations of individual members of the groups as set forth in the list above, but may also be made in the absence of the members that have been omitted from the whole group to form the subgroup. The subgroup formed by omitting various members from the whole group in the lists above may, moreover, be an individual member of the whole group such that the dopant metal or fluorinated solvent system (or pair thereof) may be selected in the absence of all other members of the whole group except the selected individual member.

In this specification, unless explicitly stated otherwise or indicated to the contrary by the context of
usage, where an embodiment of the subject matter hereof is stated or described as comprising, including, containing, having, being composed of or being constituted by or of certain features or elements, one or more features or elements in addition to those explicitly stated or described may be present in the embodiment. An alternative embodiment of the subject matter hereof, however, may be stated or described as consisting essentially of certain features or elements, in which embodiment features or elements that would materially alter the principle of operation or the distinguishing characteristics of the embodiment are not present therein. A further alternative embodiment of the subject matter hereof may be stated or described as consisting of certain features or elements, in which embodiment, or in insubstantial variations thereof, only the features or elements specifically stated or described are present.

Where a range of numerical values is recited or established herein, the range includes the endpoints thereof and all the individual integers and fractions within the range, and also includes each of the narrower ranges therein formed by all the various possible combinations of those endpoints and internal integers and fractions to form subgroups of the larger group of values within the stated range to the same extent as if each of those narrower ranges was explicitly recited. Where a range of numerical values is stated herein as being greater than a stated value, the range is nevertheless finite and is bounded on its upper end by a value that is
operable within the context of the invention as described herein. Where a range of numerical values is stated herein as being less than a stated value, the range is nevertheless bounded on its lower end by a non-zero value.

In this specification, unless explicitly stated otherwise or indicated to the contrary by the context of usage,

(a) lists of compounds, monomers, oligomers, polymers and/or other chemical materials include derivatives of the members of the list in addition to mixtures of two or more of any of the members and/or any of their respective derivatives; and

(b) amounts, sizes, ranges, formulations, parameters, and other quantities and characteristics recited herein, particularly when modified by the term "about", may but need not be exact, and may also be approximate and/or larger or smaller (as desired) than stated, reflecting tolerances, conversion factors, rounding off, measurement error and the like, as well as the inclusion within a stated value of those values outside it that have, within the context of this invention, functional and/or operable equivalence to the stated value.
CLAIMS

What is claimed is:

1. An electrolyte composition comprising:
   (a) at least one electrolyte salt; and
   (b) a solvent mixture comprising ethylene carbonate at a concentration of about 10% to about 50% by weight of the solvent mixture; and CH₂CO₂CH₂CF₃ at a concentration of about 50% to about 90% by weight of the solvent mixture.

2. The electrolyte composition of Claim 1, wherein the electrolyte salt is selected from one or more members of the group consisting of:
   lithium hexafluorophosphate, Li PF₆(CF₂CF₃)₃,
   lithium bis(trifluoromethanesulfonyl)imide,
   lithium bis(perfluoroethanesulfonyl)imide,
   lithium (fluorosulfonyl)
   (nonafluorobutanesulfonyl)imide,
   lithium bis(fluorosulfonyl)imide,
   lithium tetrafluoroborate,
   lithium perchlorate,
   lithium hexafluoroarsenate,
   lithium trifluoromethanesulfonate,
   lithium tris(trifluoromethanesulfonyl)methide,
   lithium bis(oxalato)borate,
   lithium difluoro(oxalato)borate,
   Li₂B₁₂F₁₂₋ₓHₓ where x is equal to 0 to 8, and
   a mixture of lithium fluoride and an anion receptor.
3. The electrolyte composition of Claim 2 wherein the electrolyte salt is lithium hexafluorophosphate.

4. The electrolyte composition of Claim 1, wherein the ethylene carbonate comprises about 30% by weight of the solvent mixture and the \( \text{CH}_3\text{CO}_2\text{CH}_2\text{CF}_2\text{H} \) comprises about 70% by weight of the solvent mixture.

5. The electrolyte composition of claim 1 further comprising fluoroethylene carbonate at a concentration of about 0.01% to less than 2% by weight of the electrolyte composition.

6. The electrolyte composition of claim 5, wherein the fluoroethylene carbonate comprises about 1% by weight of the electrolyte composition.

7. An electrochemical cell comprising:
   (a) a housing;
   (b) an anode and a cathode disposed in said housing and in conductive contact with one another;
   (c) an electrolyte composition disposed in said housing and providing an ionically conductive pathway between said anode and said cathode, wherein the electrolyte composition comprises:
      (i) at least one electrolyte salt; and
      (ii) a solvent mixture comprising ethylene carbonate at a concentration of about 10% to about 50% by weight of the solvent mixture; and \( \text{CH}_3\text{CO}_2\text{CH}_2\text{CF}_2\text{H} \) at a
concentration of about 50% to about 90% by weight of the solvent mixture; and

(d) a porous separator between said anode and said cathode.

8. The electrochemical cell of Claim 7, wherein the ethylene carbonate comprises about 30% by weight of the solvent mixture and the CH₂CO₂CH₂CF₂H comprises about 70% by weight of the solvent mixture.

9. The electrochemical cell of claim 7, wherein the solvent mixture further comprises fluoroethylene carbonate at a concentration of about 0.01% to less than 2% by weight of the electrolyte composition.

10. The electrochemical cell of claim 9, wherein the fluoroethylene carbonate comprises about 1% by weight of the electrolyte composition.

11. The electrochemical cell of claim 7, wherein said electrochemical cell is a lithium ion battery.

12. An electronic device comprising an electrochemical cell according to claim 7.
