This application is related to U.S. Provisional Application Serial No. 60/913,216 filed April 20, 2007 and U.S. Application Serial No. 12/105,408 filed April 18, 2008, the contents of both of which are incorporated by reference herein in their entireties.

FIELD OF THE INVENTION

[0002] The present invention relates to novel kinase inhibitors and modulator compounds useful for the treatment of various diseases. More particularly, the invention is concerned with such compounds, methods of treating diseases, and methods of synthesis of the compounds. Preferably, the compounds are useful for the modulation of kinase activity of c-ABL, c-KIT, VEGFR, PDGFR, FLT-3, c-MET, FGFR, the HER family, cFMS, RET, oncogenic forms thereof, disease causing polymorphs thereof, and aberrant fusion proteins thereof.

BACKGROUND OF THE INVENTION

[0003] Several members of the protein kinase family have been clearly implicated in the pathogenesis of various proliferative and myeloproliferative diseases and thus represent important targets for treatment of these diseases. Some of the proliferative diseases relevant to this invention include cancer, rheumatoid arthritis, atherosclerosis, and retinopathies. Important examples of kinases which have been shown to cause or contribute to the pathogenesis of these diseases include c-ABL kinase and the oncogenic fusion protein BCR-ABL kinase; c-KIT kinase, c-MET, the HER family of kinases, PDGF receptor kinases; VEGF receptor kinases; FLT-3 kinase, RET kinase, and c-FMS kinase.

[0004] c-ABL kinase is an important non-receptor tyrosine kinase involved in cell signal transduction. This ubiquitously expressed kinase--- upon activation by upstream signaling factors including growth factors, oxidative stress, integrin stimulation, and ionizing radiation---localizes to the cell plasma membrane, the cell nucleus, and other cellular compartments including the actin cytoskeleton (Van Etten, *Trends Cell Biol.* (1999) 9: 179). There are two normal isoforms of ABL kinase: ABL-1A and ABL-1B. The N-terminal half of c-ABL kinase is important for autoinhibition of the kinase domain catalytic activity (Pluk *et al*, *Cell* (2002) 108: 247). Details of the mechanistic aspects of this autoinhibition have recently been disclosed (Nagar *et al*, *Cell* (2003) 112: 859). The N-terminal myristoyl amino acid residue of ABL-1B has been shown to intramolecularly occupy a hydrophobic pocket formed from alpha-helices in the C-lobe of the kinase domain. Such intramolecular binding induces a novel binding area for intramolecular docking of the SH2 domain and the SH3 domain onto the kinase domain, thereby distorting and inhibiting the catalytic activity of the kinase. Thus, an intricate intramolecular negative regulation of the kinase activity is brought about by these N-terminal regions of c-ABL kinase. An aberrant dysregulated form of c-ABL is formed from a chromosomal translocation event, referred to as the Philadelphia chromosome (P.C. Nowell *et al*, *Science* (1960) 132: 1497; J.D. Rowley, *Nature* (1973) 243: 290). This abnormal chromosomal translocation leads aberrant gene fusion between the ABL kinase gene and the breakpoint cluster region (BCR) gene, thus encoding an aberrant protein called BCR-ABL (G. Q. Daley *et al*, *Science* (1990) 247: 824; M. L. Gishizky *et al*, *Proc. Natl. Acad. Sci. USA* (1993) 90: 3755; S. Li *et al*, *J. Exp. Med.* (1999) 189: 1399). The BCR-ABL fusion protein does not include the regulatory myristoylation site (B. Nagar *et al*, *Cell* (2003) 112: 859) and as a result functions as an oncoprotein which causes chronic myeloid leukemia (CML). CML is a malignancy of pluripotent hematopoietic stem cells. The p210 form of BCR-ABL is seen in 95% of patients with CML, and in 20% of patients with acute lymphocytic leukemia and is exemplified by sequences such as e14a2 and e13a2. The corresponding p190 form, exemplified by the sequence e1a2 has also been identified. A p185 form has also been disclosed and has been linked to being causative of up to 10% of patients with acute lymphocytic leukemia. It will be appreciated by one skilled in the art that “p210 form”, “p190 form” and “p185 form” each describe a closely related group of fusion proteins, and that Sequence ID’s used herein are merely representative of each form and are not meant to restrict the scope solely to those sequences.

[0005] c-KIT (KIT, CD117, stem cell factor receptor) is a 145 kDa transmembrane tyrosine kinase protein that acts as a type-III receptor (Pereira *et al.* J Carcin. (2005), 4: 19). The c-KIT proto-oncogene, located on chromosome 4q11-21, encodes the c-KIT receptor, whose ligand is the stem cell factor (SCF, steel factor, c-KIT ligand, mast cell growth factor, Morstyn G, *et al.* *Oncology* (1994) **51**(2):205. Yarden Y, *et al.* *Embo J* (1987) **6**(11):3341). The receptor has tyrosine-protein kinase activity and binding of the ligands leads to the autophosphorylation of c-KIT and its association with substrates such as phosphatidylinositol 3-kinase (Pi3K). Tyrosine phosphorylation by protein tyrosine kinases is of particular importance in cellular signaling and can mediate signals for major cellular processes, such as proliferation, differentiation, apoptosis, attachment, and migration. Defects in c-KIT are a cause of piebaldism, an autosomal dominant genetic developmental abnormality of pigmentation characterized by congenital patches of white skin and hair that lack melanocytes. Gain-of-function mutations of the c-KIT gene and the expression of phosphorylated c-KIT are found in most gastrointestinal stromal tumors and mastocytosis. Further, almost all gonadal seminomas/dysgerminomas exhibit c-KIT membranous staining, and several reports have clarified that some (10-25%) have a c-KIT gene mutation (Sakuma, Y. *et al.* *Cancer Sci* (2004) 95:9, 716). C-KIT defects have also been associated with testicular tumors including germ cell tumors (GCT) and testicular germ cell tumors (TGCT).

[0006] The role of c-KIT expression has been studied in hematologic and solid tumors, such as acute leukemias (Cortes J. *et al.* *Cancer* (2003) **97**(11):2760) and gastrointestinal stromal tumors (GIST, Fletcher C.D. *et al.* *Hum Pathol* (2002) **33**(5):459). The clinical importance of c-KIT expression in malignant tumors relies on studies with Gleevec[®] (imatinib mesylate, STI571, Novartis Pharma AG Basel, Switzerland) that specifically inhibits tyrosine kinase receptors (Lefevre G. *et al.* *J Biol Chem* (2004) **279**(30):31769). Moreover, a clinically relevant breakthrough has been the finding of anti-tumor effects of this compound in GIST, a group of tumors regarded as being generally resistant to conventional chemotherapy (de Silva CM, Reid R: *Pathol Oncol Res* (2003) **9**(1):13-19). GIST most often become Gleevec resistant and molecularly targeted small therapies that target c-KIT mutations remain elusive.

[0007] c-MET is a unique receptor tyrosine kinase (RTK) located on chromosome 7p and activated via its natural ligand hepatocyte growth factor. c-MET is found mutated in a variety of solid tumors (Ma P.C. *et al. Cancer Metastasis* (2003) 22:309). Mutations in the tyrosine kinase domain are associated with hereditary papillary renal cell carcinomas (Schmidt L *et al. Nat. Genet.* (1997)16:68; Schmidt L, *et al. Oncogene* (1999) 18:2343), whereas mutations in the sema and juxtamembrane domains are often found in small cell lung cancers (SCLC; Ma P.C. *et al. Cancer Res* (2003) 63:6272). Many activating mutations are also found in breast cancers (Nakopoulou *et al. Histopath* (2000) 36(4): 313). The panoply of tumor types for which c-MET mediated growth has been implicated suggests this is a target ideally suited for modulation by specific c-MET small molecule inhibitors.

[0008] The *TPR-MET* oncogene is a transforming variant of the c-MET RTK and was initially identified after treatment of a human osteogenic sarcoma cell line transformed by the chemical carcinogen *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (Park M. *et al. Cell* (1986) 45:895). The TPR-MET fusion oncoprotein is the result of a chromosomal translocation, placing the *TPR3* locus on chromosome 1 upstream of a portion of the *c-MET* gene on chromosome 7 encoding only for the cytoplasmic region. Studies suggest that TPR-MET is detectable in experimental cancers (e.g. Yu J. *et al. Cancer* (2000) 88:1801). Dimerization of the M_r 65,000 TPR-MET oncoprotein through a leucine zipper motif encoded by *TPR* leads to constitutive activation of the c-MET kinase (Zhen Z. *et al. Oncogene* (1994) 9:1691). TPR-MET activates wild-type c-MET RTK and can activate crucial cellular growth pathways, including the Ras pathway (Aklilu F. *et al. Am J Physiol* (1996) 271:E277) and the phosphatidylinositol 3-kinase (PI3K)/AKT pathway (Ponzetto C. *et al. Mol Cell Biol* (1993) 13:4600). Conversely, in contrast to c-MET RTK, TPR-MET is ligand independent, lacks the CBL binding site in the juxtamembrane region in c-MET, and is mainly cytoplasmic. c-MET immunohistochemical expression seems to be associated with abnormal β -catenin expression, and provides good prognostic and predictive factors in breast cancer patients.

[0009] The majority of small molecule kinase inhibitors that have been reported have been shown to bind in one of three ways. Most of the reported inhibitors interact with the ATP binding domain of the active site and exert their effects by competing with ATP for occupancy. Such inhibitors are referred to as Type 1 kinase inhibitors. Other inhibitors have been shown to bind to a separate hydrophobic region of the

protein known as the “DFG-in-conformation” pocket, and still others have been shown to bind to both the ATP domain and the “DFG-in-conformation” pocket. The latter two types of kinase inhibitors are referred to as Type II kinase inhibitors. Some of the kinase inhibitors of the present invention are Type II inhibitors. Examples specific to inhibitors of Raf kinases can be found in Lowinger *et al*, *Current Pharmaceutical Design* (2002) 8: 2269-2278; Dumas, J. *et al*, *Current Opinion in Drug Discovery & Development* (2004) 7: 600-616; Dumas, J. *et al*, WO 2003068223 A1 (2003); Dumas, J., *et al*, WO 9932455 A1 (1999), and Wan, P.T.C., *et al*, *Cell* (2004) 116: 855-867.

[0010] Physiologically, kinases are regulated by a common activation/deactivation mechanism wherein a specific activation loop sequence of the kinase protein binds into a specific pocket on the same protein which is referred to as the switch control pocket (see WO 2004061084 and WO 2007008917 for further details). Such binding occurs when specific amino acid residues of the activation loop are modified for example by phosphorylation, oxidation, or nitrosylation. The binding of the activation loop into the switch pocket results in a conformational change of the protein into its active form (Huse, M. and Kuriyan, J. *Cell* (109) 275-282). Some of the inhibitors of the present invention induce kinases to adopt inactive conformations through inhibitor binding at least in part into the switch control pocket.

See Ettmayer et. al, *J. Med. Chem.*, 2004, 47 (10): 2393-2404 and Lorenzi et. al, *J. Pharm. Exp. Therapeutics*, 2005, 883-900 for reviews.

[0029] Structural, chemical and stereochemical definitions are broadly taken from IUPAC recommendations, and more specifically from Glossary of Terms used in Physical Organic Chemistry (IUPAC Recommendations 1994) as summarized by P. Müller, *Pure Appl. Chem.*, 66, 1077-1184 (1994) and Basic Terminology of Stereochemistry (IUPAC Recommendations 1996) as summarized by G.P. Moss *Pure and Applied Chemistry*, 68, 2193-2222 (1996). Specific definitions are as follows:

[0030] Atropisomers are defined as a subclass of conformers which can be isolated as separate chemical species and which arise from restricted rotation about a single bond.

[0031] Regioisomers or structural isomers are defined as isomers involving the same atoms in different arrangements.

[0032] Enantiomers are defined as one of a pair of molecular entities which are mirror images of each other and non-superimposable.

[0033] Diastereomers or diastereoisomers are defined as stereoisomers other than enantiomers. Diastereomers or diastereoisomers are stereoisomers not related as mirror images. Diastereoisomers are characterized by differences in physical properties, and by some differences in chemical behavior towards achiral as well as chiral reagents.

[0034] Tautomerism is defined as isomerism of the general form $G-X-Y=Z \rightleftharpoons X=Y-Z-G$ where the isomers (called tautomers) are readily interconvertible; the atoms connecting the groups X,Y,Z are typically any of C, H, O, or S, and G is a group which becomes an electrofuge or nucleofuge during isomerization. The commonest case, when the electrofuge is H^+ , is also known as "prototropy."

[0035] Tautomers are defined as isomers that arise from tautomerism, independent of whether the isomers are isolable.

Dosage

[0051] The methods of the present invention may be used to prevent, treat, or reduce the severity of cancer or hyperproliferative diseases. The exact amount required will vary from subject to subject, depending on the species, age, and general condition of the subject, the severity of the disease, the particular agent, its mode of administration, and the like. The compounds of the invention are preferably formulated in dosage unit form for ease of administration and uniformity of dosage. The expression "dosage unit form" as used herein refers to a physically discrete unit of agent appropriate for the patient to be treated. It will be understood, however, that the total daily usage of the compounds and compositions of the present invention will be decided by the attending physician within the scope of sound medical judgment. The specific effective dose level for any particular patient or organism will depend upon a variety of factors including the disorder being treated and the severity of the disorder; the activity of the specific compound employed; the specific composition employed; the age, body weight, body surface area, general health, sex, ethnicity and diet of the patient; the time of administration, route of administration, and rate of excretion of the specific compound employed; the duration of the treatment; drugs used in combination or coincidental with the specific compound employed, and like factors well known in the medical arts. The term "patient," as used herein, means an animal, preferably a mammal, and most preferably a human.

[0052] Administration of a compound of the invention or pharmaceutically active agent described herein can be accomplished via any mode of administration for therapeutic agents. These modes include systemic or local administration such as oral, nasal, parenteral, transdermal, subcutaneous, vaginal, buccal, rectal or topical administration modes. In some instances, administration will result in the release of the inhibitor or pharmaceutically active agent described herein into the bloodstream.

[0053] In one embodiment, the inhibitor or pharmaceutically active agent described herein is administered orally.

[0054] Depending on the intended mode of administration, the compositions can be in solid, semi-solid or liquid dosage form, such as, for example, injectables, tablets, suppositories, pills, time-release capsules, elixirs, tinctures, emulsions, syrups, powders, liquids, suspensions, or the like, preferably in unit dosages and consistent with conventional pharmaceutical practices. Likewise, they can also be administered in intravenous (both bolus and infusion), intraperitoneal, subcutaneous or intramuscular form, all using forms well known to those skilled in the pharmaceutical arts.

[0055] Liquid dosage forms for oral administration include, but are not limited to, pharmaceutically acceptable emulsions, microemulsions, solutions, suspensions, syrups and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents, solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butyleneglycol, dimethylformamide, oils (in particular, cottonseed, groundnut, corn, germ, olive, castor, and sesame oils), glycerol, tetrahydrofurfuryl alcohol, polyethyleneglycols and fatty acid esters of sorbitan, and mixtures thereof. Besides inert diluents, the oral compositions can also include adjuvants such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, and perfuming agents.

[0056] Injectable preparations, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using dissolution or suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution, suspension or emulsion in a nontoxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed

are water, aqueous dextrose, glycerol, ethanol, Ringer's solution, U.S.P. and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil can be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid are used in the preparation of injectables.

[0057] The injectable formulations can be sterilized, for example, by filtration through a bacterial-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions which can be dissolved or dispersed in sterile water or other sterile injectable medium prior to use.

[0058] In order to prolong the effect of a compound of the present invention, it is often desirable to slow the absorption of the compound from subcutaneous injection or intramuscular injection, or to slow the rate of systemic absorption upon oral administration. This may be accomplished by the use of a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the compound then depends upon its rate of dissolution that, in turn, may depend upon crystal size and crystalline form. Modified or sustained release formulations, well known in the art, may also be utilized in formulations to control the rate of absorption of an orally administered compound. Alternatively, modified or sustained absorption of a parenterally administered compound form is accomplished by dissolving or suspending the compound in an oil vehicle. Injectable depot forms are made by forming microcapsule matrices of the compound in biodegradable polymers such as polylactide-polyglycolide. Depending upon the ratio of compound to polymer and the nature of the particular polymer employed, the rate of compound release can be controlled. Examples of other biodegradable polymers include poly(orthoesters) and poly(anhydrides). Depot injectable formulations are also prepared by entrapping the compound in liposomes or microemulsions that are compatible with body tissues.

[0059] Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is mixed with at least one inert, pharmaceutically acceptable excipient or carrier such as sodium citrate or dicalcium phosphate and/or a) fillers or extenders or diluents such as starches, lactose, sucrose, glucose, mannitol, cellulose, saccharin, glycine, and silicic acid, b) binders such as, for example, magnesium aluminum silicate, starch paste,

tragacanth, carboxymethylcellulose, methyl cellulose, alginates, gelatin, polyvinylpyrrolidinone, magnesium carbonate, natural sugars, corn sweeteners, sucrose, waxes and natural or synthetic gums such as acacia, c) humectants such as glycerol, d) disintegrating agents such as agar--agar, calcium carbonate, potato or tapioca starch, alginic acid, certain silicates, and sodium carbonate, e) solution retarding agents such as paraffin, f) absorption accelerators or disintegrants such as quaternary ammonium compounds, starches, agar, methyl cellulose, bentonite, xanthangum, algiic acid, and effervescent mixtures, g) wetting agents such as, for example, cetyl alcohol and glycerol monostearate, h) absorbents such as kaolin and bentonite clay, and i) lubricants such as talc, silica, stearic acid, calcium stearate, magnesium stearate, sodium oleate, sodium acetate, sodium chloride, solid polyethylene glycols, sodium lauryl sulfate, and mixtures thereof. In the case of capsules, tablets and pills, the dosage form may also comprise buffering agents.

[0060] Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight polyethylene glycols and the like. The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings and other coatings well known in the pharmaceutical formulating art. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a modified or sustained manner. Examples of embedding compositions that can be used include polymeric substances and waxes. Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight poethylene glycols and the like.

In such solid dosage forms the active compound may be admixed with at least one inert diluent such as sucrose, lactose or starch. Such dosage forms may also comprise, as is normal practice, additional substances other than inert diluents, e.g., tableting lubricants and other tableting aids such a magnesium stearate

and microcrystalline cellulose. In the case of capsules, tablets and pills, the dosage forms may also comprise buffering agents. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a modified or sustained manner. Examples of embedding compositions that can be used include polymeric substances and waxes.

[0063] The compound of the invention or pharmaceutically active agent described herein can also be delivered by the use of monoclonal antibodies as individual carriers to which the compound or pharmaceutically active agent described herein are coupled or conjugated. The compound or pharmaceutically active agent described herein can also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamide-phenol, polyhydroxyethylaspanamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues. [0064] Furthermore, a compound or pharmaceutically active agent described herein may be coupled, absorbed, adsorbed, or conjugated to a medical device including but not limited to stents.

[0065] Parenteral injectable administration can be used for subcutaneous, intramuscular, intra-articular, or intravenous injections and infusions. Injectables can be prepared in conventional forms, either as liquid solutions or suspensions or solid forms suitable for dissolving in liquid prior to injection.

[0066] One embodiment, for parenteral administration employs the implantation of a slow-release or sustained-released system, according to U.S. Pat. No. 3,710,795, incorporated herein by reference.

[0067] The compositions can be sterilized or contain non-toxic amounts of adjuvants, such as preserving, stabilizing, wetting or emulsifying agents, solution promoters, salts for regulating the osmotic pressure, pH buffering agents, and other substances, including, but not limited to, sodium acetate or triethanolamine oleate. In addition, they can also contain other therapeutically valuable substances.

[0068] Dosage forms for topical or transdermal administration of a compound of this invention include ointments, pastes, creams, lotions, gels, powders, solutions, sprays, inhalants or patches. The compound or pharmaceutically active agent described herein is admixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives or buffers as may be required. Ophthalmic formulation, ear drops, and eye drops are also contemplated as being within the scope of this invention. Furthermore, the compound or pharmaceutically active agent described herein can be administered in intranasal form via topical use of suitable intranasal vehicles. Additionally, the present invention contemplates the use of transdermal patches or via other transdermal routes, using those forms of transdermal skin patches and formulations well known to those of ordinary skill in that art. Transdermal patches have the added advantage of providing controlled delivery of a compound to the body. Such dosage forms can be made by dissolving or dispensing the compound in the proper medium. Absorption enhancers can also be used to increase the flux of the compound across the skin. The rate can be controlled by either providing a rate controlling membrane or by dispersing the compound in a polymer matrix or gel.

A person skilled in the art can readily determine and prescribe the effective amount of the drug useful for treating or preventing a proliferative disorder.

[0071] Effective dosage amounts of the compound of the invention or pharmaceutically active agent described herein, when administered to a subject, range from about 0.05 to about 3,500 mg of compound or pharmaceutically active agent described herein per day. Unit dosage compositions for in vivo or in vitro use can contain about 0.01, 0.5, 1.0, 2.5, 5.0, 10.0, 15.0, 25.0, 50.0, 100.0, 250.0, 500.0 or 1000.0 mg of the compound described herein. The amount of a compound of the invention or pharmaceutically active agent described herein that is effective in the treatment or prevention of cancer or hyperproliferative disease can be determined by clinical techniques that are known to those of skill in the art. In addition, in vitro and in vivo assays can optionally be employed to help identify optimal dosage ranges. The precise dose to be employed can also depend on the route of administration, and the seriousness of the proliferative disorder being treated and can be decided according to the judgment of the practitioner and each subject's circumstances in view of, e.g., published clinical studies. Suitable effective dosage amounts, however, can range from about 10 micrograms to about 5 grams about every 4 h, although they are typically about 500 mg or less per every 4 hours. [0081] The amount of both, an inventive compound and additional therapeutic agent (in those compositions which comprise an additional therapeutic agent as described above) that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated and the particular mode of administration. Preferably, compositions of this invention should be formulated so that a dosage of between 0.01 - 100 mg/kg body weight/day of an inventive can be administered.

[0082] In those compositions which comprise an additional therapeutic agent, that additional therapeutic agent and the compound of this invention may act synergistically. Therefore, the amount of additional therapeutic agent in such compositions will be less than that required in a monotherapy utilizing only that therapeutic agent. In such compositions a dosage of between 0.01 - 100 mg/kg body weight/day of the additional therapeutic agent can be administered.

[0083] The amount of additional therapeutic agent present in the compositions of this invention will be no more than the amount that would normally be administered in a composition comprising that therapeutic agent as the only active agent. Preferably the amount of additional therapeutic agent in the presently disclosed compositions will range from about 50% to 100% of the amount normally present in a composition comprising that agent as the only therapeutically active agent.

[0084] In some embodiments, the compositions comprise an amount of an anticancer inhibitor described herein, e.g., a kinase inhibitor, and another anticancer agent which together are effective to treat or prevent cancer. In another embodiment, the amount of the anticancer inhibitor described herein and another anticancer agent is at least about 0.01% of the combined combination chemotherapy agents by weight of the composition. When intended for oral administration, this amount can be varied from about 0.1% to about 80% by weight of the composition. Some oral compositions can comprise from about 4% to about 50% of the anticancer inhibitor described herein and another anticancer agent. Other compositions of the present invention are prepared so that a parenteral dosage unit contains from about 0.01% to about 2% by weight of the composition.

[0085] The present methods for treating or preventing cancer or a hyperproliferative disease in a subject in need thereof can further comprise administering another prophylactic or therapeutic agent to the subject being administered an anticancer inhibitor or an anti-proliferative inhibitor described herein. In one embodiment the other prophylactic or therapeutic agent is administered in an effective amount. The other prophylactic or therapeutic agent includes, but is not limited to, an anti-inflammatory agent, an anti-renal failure agent, an anti-diabetic agent, an anti-cardiovascular disease agent, an antiemetic agent, a hematopoietic colony stimulating factor, an anxiolytic agent, and an opioid or non-opioid analgesic agent.

[0087] In another embodiment, the anticancer inhibitor described herein can be administered prior to, concurrently with, or after a hematopoietic colony stimulating factor, or on the same day, or within 1 hour, 2 hours, 12 hours, 24 hours, 48 hours, 72 hours, 1 week, 2 weeks, 3 weeks or 4 weeks of each other.

[0088] In still another embodiment, the anticancer inhibitor described herein can be administered prior to, concurrently with, or after an opioid or non-opioid analgesic agent, or on the same day, or within 1 hour, 2 hours, 12 hours, 24 hours, 48 hours or 72 hours of each other.

[0090] Effective amounts of the other therapeutic agents are well known to those skilled in the art. However, it is well within the skilled artisan's purview to determine the other therapeutic agent's optimal effective amount range. In one embodiment of the invention, where, another therapeutic agent is administered to a subject, the effective amount of the anticancer compound or anti-proliferative compound described herein is less than its effective amount would be where the other therapeutic agent is not administered. In this case, without being bound by theory, it is believed that the anticancer compound or anti-proliferative compound described herein and the other therapeutic agent act synergistically to treat or prevent cancer or hyperproliferative disease.

1.3 *Pharmaceutical Preparations*

[0096] The compounds of the invention, especially those of section 1 may form a part of a pharmaceutical composition by combining one or more such compounds with a pharmaceutically acceptable carrier. Additionally, the compositions may include an additive selected from the group consisting of adjuvants, excipients, diluents, and stabilizers.

Section 2. *Synthesis of compounds of the present invention*

[0097] The compounds of the invention are available by the procedures and teachings of WO 2006/071940, incorporated by reference, and by the general synthetic methods illustrated in the Schemes below and the accompanying examples.

[0098] As indicated in Scheme 1, ureas of general formula 1 can be readily prepared by the union of amines of general formula 2 with isocyanates 3 or isocyanate surrogates, for example trichloroethyl carbamates (4) or isopropenyl carbamates (5). Preferred conditions for the preparation of compounds of general formula 1 involve heating a solution of 4 or 5 with 2 in the presence of a tertiary base such as diisopropylethylamine, triethylamine or N-methylpyrrolidine in a solvent such as dimethylformamide, dimethylsulfoxide, tetrahydrofuran or 1,4-dioxane at a temperature between 50 and 100 °C for a period of time ranging from 1 hour to 2 days.

Scheme 1

[0099] As shown in Scheme 2, isocyanates **3** can be prepared from amines A-NH₂ **6** with phosgene, or a phosgene equivalent such as diphosgene, triphosgene, or N,N-dicarbonylimidazole. Trichloroethyl carbamates **4** and isopropenyl carbamates **5** are readily prepared from amines A-NH₂ (**6**) by acylation with trichloroethyl chloroformate or isopropenyl chloroformate by standard conditions familiar to those skilled in the art. Preferred conditions for the preparation of **4** and **5** include treatment of compound **6** with the appropriate chloroformate in the presence of pyridine in an aprotic solvent such as dichloromethane or in the presence of aqueous hydroxide or carbonate in a biphasic aqueous/ethyl acetate solvent system.

Scheme 2

[0100] Additionally, compounds of formula **1** can also be prepared from carboxylic acids **7** by the intermediacy of in-situ generated acyl azides (Curtius rearrangement) as indicated in Scheme 3. Preferred conditions for Scheme 3 include the mixing of acid **7** with amine **2** and diphenylphosphoryl azide in a solvent such as 1,4-dioxane or dimethylformamide in the presence of base, such as triethylamine, and raising the temperature of the reaction to about 80-120 °C to affect the Curtius rearrangement.

Scheme 3

[0101] By analogy to Schemes 1 and 3 above, it will be recognized by those skilled in the art that the compounds of formula 1 can also be prepared by the union of amines $A-NH_2$ 6 with isocyanates 8 (Scheme 4). Isocyanates 8 can be prepared from general amines 2 by standard synthetic methods. Suitable methods for example, include reaction of 2 with phosgene, or a phosgene equivalent such as diphosgene, triphosgene, or N,N-dicarbonylimidazole. In addition to the methods above for converting amines 2 into isocyanates 8, the isocyanates 8 can also be prepared *in situ* by the Curtius rearrangement and variants thereof. Those skilled in the art will further recognize that isocyanates 8 need not be isolated, but may be simply generated *in situ*. Accordingly, acid 9 can be converted to compounds of formula 1 either with or without isolation of 8. Preferred conditions for the direct conversion of acid 9 to compounds of formula 1 involve the mixing of acid 9, amine $A-NH_2$ 6, diphenylphosphoryl azide and a suitable base, for example triethylamine, in an aprotic solvent, for example dioxane. Heating said mixture to a temperature of between 80 and 120 °C provides the compounds of formula 1.

Scheme 4

[0102] Additionally, compounds of formula **1** can also be prepared from amines **2** by first preparing stable isocyanate equivalents, such as carbamates (Scheme 5). Especially preferred carbamates include trichloroethyl carbamates (**10**) and isopropenyl carbamates (**11**) which are readily prepared from amine **2** by reaction with trichloroethyl chloroformate or isopropenyl chloroformate respectively using standard conditions familiar to those skilled in the art. Further reaction of carbamates **10** or **11** with amine $\text{A}-\text{NH}_2 **6** provides compounds of formula **1**. Those skilled in the art will further recognize that certain carbamates can also be prepared from acid **9** by Curtius rearrangement and trapping with an alcoholic co-solvent. For example, treatment of acid **9** (Scheme 5) with diphenylphosphoryl azide and trichloroethanol at elevated temperature provides trichloroethyl carbamate **10**.$

Scheme 5

[0103] Many methods exist for the preparation of amines $\text{A}-\text{NH}_2$ **6** and acids $\text{A}-\text{CO}_2\text{H}$ **7**, depending on the nature of the A-moiety. Indeed, many such amines (**6**) and acids (**7**) useful for the preparation of compounds of formula **1** are available from commercial vendors. Some non-limiting preferred synthetic methods for the preparation of amines **6** and acids **7** are outlined in the following schemes and accompanying examples.

[0104] As illustrated in Scheme 6, Z4-substituted pyrazol-5-yl amines 14 (a preferred aspect of A-NH₂ 6, Scheme 2) are available by the condensation of hydrazines 12 and beta-keto nitriles 13 in the presence of a strong acid. Preferred conditions for this transformation are by heating in ethanolic HCl. Many such hydrazines 12 are commercially available. Others can be prepared by conditions familiar to those skilled in the art, for example by the diazotization of amines followed by reduction or, alternately from the reduction of hydrazones prepared from carbonyl precursors.

Scheme 6

[0105] Another preferred method for constructing Z4-substituted pyrazoles is illustrated by the general preparation of pyrazole acids 19 and 20. (Scheme 7), aspects of of general acid A-CO₂H 7 (Scheme 3). As indicated in Scheme 7, pyrazole 5-carboxylic esters 17 and 18 can be prepared by the alkylation of pyrazole ester 16 with Z4-X 15, wherein X represents a leaving group on a Z4 moiety such as a halide, triflate, or other sulfonate. Preferred conditions for the alkylation of pyrazole 16 include the use of strong bases such as sodium hydride, potassium tert-butoxide and the like in polar aprotic solvents such as dimethylsulfoxide, dimethylformamide or tetrahydrofuran. Z4-substituted pyrazoles 17 and 18 are isomers of one another and can both be prepared in the same reactions vessel and separated by purification methods familiar to those skilled in the art. The esters 17 and 18 in turn can be converted to acids 19 and 20 using conditions familiar to those skilled in the art, for example saponification in the case of ethyl esters, hydrogenation in the case of benzyl esters or acidic hydrolysis in the case of tert-butyl esters.

Scheme 7

[0106] Scheme 8 illustrates the preparation of pyrazole amine 25, a further example of general amine A-NH₂ 6. Acid-catalyzed condensation of R₂-substituted hydrazine 21 with 1,1,3,3-tetramethoxypropane 22 provides R₂-substituted pyrazole 23. Those skilled in the art will further recognize that R₂-substituted pyrazole 23 can also be prepared by direct alkylation of pyrazole. Pyrazole 23 can be regioselectively nitrated to provide nitro-pyrazole 24 by standard conditions familiar to those skilled in the art. Finally, hydrogenation of nitro-pyrazole 24 employing a hydrogenation catalyst, such as palladium or nickel provides pyrazole amine 25, an example of general amine A-NH₂ 6.

Scheme 8

[0107] Additional pyrazoles useful for the synthesis of compounds of formula 1 can be prepared as described in Scheme 9. Thus, keto-ester 26 can be reacted with N,N-dimethylformamide dimethyl acetal to provide 27. Reaction of 27 with either 21 or 28 (wherein P is an acid-labile protecting group) in the presence of acid provides 29 or 30. In practice, both 29 and 30 can be obtained from the same reaction and can be separated by standard chromatographic conditions. In turn, esters 29 and 30 can be converted to acids 31 and 32 respectively as described in Scheme 7.

Scheme 9

[0108] In a manner similar to Scheme 9, NH-pyrazole 34 can be prepared by reaction of acrylate 33 with hydrazine (Scheme 10). Alkylation of 34 with R²-X 35 as described above for Scheme 7 provides mixtures of pyrazole esters 36 and 37 which are separable by standard chromatographic techniques. Further conversion of esters 36 and 37 to acids 38 and 39 can be accomplished as described in Scheme 7.

Scheme 10

[0109] General amines 6 containing an isoxazole ring can be prepared as described in Scheme 11. Thus, by analogy to Scheme 6, reaction of keto-nitrile 9 with hydroxylamine can provide both the 5-aminoisoxazole 40 and 3-aminoisoxazole 41. Preferred conditions for the formation of 5-aminoisoxazole 40 include the treatment of 9 with hydroxylamine in the presence of aqueous sodium hydroxide, optionally in the presence of an alcoholic co-solvent at a temperature between 0 and 100 °C. Preferred conditions for the formation of 3-aminoisoxazole 41 include the treatment of 9 with hydroxylamine hydrochloride in a polar solvent such as water, an alcohol, dioxane or a mixture thereof at a temperature between 0 and 100 °C.

Scheme 11

[0110] Amines 2 useful for the invention can be synthesized according to methods commonly known to those skilled in the art. Amines of general formula 2 contain three rings and can be prepared by the stepwise union of three monocyclic subunits as illustrated in the following non-limiting Schemes. Scheme 12 illustrates one mode of assembly in which an E-containing subunit 42 is combined with the central pyridine ring 43 to provide the bicyclic intermediate 44. In one aspect this general Scheme, the “M” moiety of 42 represents a hydrogen atom of a heteroatom on the X linker that participates in a nucleophilic aromatic substitution reaction with monocycle 43. Such reactions may be facilitated by the presence of bases (for example, potassium tert-butoxide), thus M may also represent a suitable counterion (for example potassium, sodium, lithium, or cesium) within an alkoxide, sulfide or amide moiety. Alternately, the “M” group can represent a metallic species (for example, copper, boron, tin, zirconium, aluminum, magnesium, lithium, silicon, etc.) on a carbon atom of the X moiety that can undergo a transition-metal-mediated coupling with monocycle 43.

[0111] The “Y” group of monocyclic species 42 is an amine or an amine surrogate, such as an amine masked by a protecting group (“P” in formula 45), a nitro group, or a carboxy acid or ester that can be used to prepare an amine via known rearrangement. Examples of suitable protecting groups “P” include but are not limited to tert-butoxycarbonyl (Boc), benzyloxycarbonyl (Cbz), and acetamide. In the instances wherein the “Y”-group of intermediate 42 is not an amine, the products of Scheme 11 will be amine surrogates such as 45 or 46 that can be converted to amine 2 by a deprotection, reduction or rearrangement (for example, Curtius rearrangement) familiar to those skilled in the art.

[0112] In these instances, the “LG” of monocycle 43 represents a moiety that can either be directly displaced in a nucleophilic substitution reaction (with or without additional activation) or can participate in a transition-mediated union with fragment 42. The W group of monocycle 43 or bicycle 44 represents a moiety that allows the attachment of the pyrazole. In one aspect, the “W” group represents a halogen atom that will participate in a transition-metal-mediated coupling with a pre-formed heterocyclic reagent (for example a boronic acid or ester, or heteroaryl stannane) to give rise to amine 2. In another aspect, the “W” group of 43 and 44 represents a functional group that can be converted to a five-membered heterocycle by an annulation reaction. Non-limiting examples of such processes would include the conversion of a cyano, formyl, carboxy, acetyl, or alkynyl moiety into a pyrazole moiety. It will be understood by those skilled in the art that such annulations may in fact be reaction sequences and that the reaction arrows in Scheme 11 may represent either a single reaction or a reaction sequence. Additionally, the “W” group of 44 may represent a leaving group (halogen or triflate) that can be displaced by a nucleophilic nitrogen atom of a pyrazole ring.

Scheme 12

[0113] Some non-limiting examples of general Scheme 12 are illustrated in the Schemes below. Scheme 13 illustrates the preparation of pyrazole 51, an example of general amine 2. In Scheme 13, commercially available 3-fluoro-4-aminophenol (47) is reacted with potassium tert-butoxide and 2,4-dichloropyridine 48 to provide chloropyridine 49. The preferred solvent for this transformation is dimethylacetamide at a temperature between 80 and 100 °C. Subsequent union of chloropyridine 49 with the commercially available pyrazole-4-boronic acid pinacol ester 50 in the presence of a palladium catalyst, preferably palladium tetrakis(triphenylphosphine), provides amine 51.

Scheme 13

[0114] Scheme 14 illustrates a non-limiting examples of Scheme 12 wherein the “W” group is a leaving group for nucleophilic aromatic substitution. Thus, amine 53, an example of general amine 2, can be prepared from general intermediate 49 by reaction with pyrazole (52). Preferred conditions include the use of polar aprotic solvents such as 1-methyl-2-pyrrolidinone, dimethylacetamide, or dimethylsulfoxide in the presence of non-nucleophilic bases such as potassium carbonate, sodium hydride, 1,8-diaza-bicyclo[5.4.0]undec-7-ene (DBU), and the like. Preferred temperatures are from ambient temperature up to about 250 °C and may optionally include the use of microwave irradiation or sonication.

Scheme 14

[0115] Scheme 15 illustrates the preparation of amine 54, a non-limiting example of a general amine of formula 2 by way of an annulation sequence according to general Scheme 12. Conversion of chloropyridine 49 into alkyne 53 can be accomplished by Sonogashira cross-coupling with trimethylsilylacetylene, followed by aqueous hydrolysis of the trimethylsilyl group, conditions familiar to those skilled in the art. Further reaction of alkyne 53 with trimethylsilyl diazomethane at elevated temperature affords the pyrazole amine 54 (see for example, Tsuzuki, et. al, *J Med. Chem.*, **2004**, (47), 2097).

Scheme 15

[0116] Additional preferred synthetic methods for the preparation of compounds of formula 1 are found in the following examples.

Section 4. Examples

[0117] General Method A: To a solution of the starting pyrazole amine (1 eq) in EtOAc were added 2,2,2-trichloroethylchloroformate (1.1 eq) and saturated NaHCO₃ (2-3 eq) at 0 °C. After stirring for 3h at RT, the layers were separated and the aqueous layer extracted with EtOAc. The combined organic extracts were washed with brine, dried (Na₂SO₄) and concentrated under vacuum to yield the crude TROC carbamate of the pyrazole amine.

[0118] To the TROC carbamate (1 eq) in DMSO were added diisopropylethylamine (2 eq), the appropriate amine (2 eq) and the mixture was stirred at 60 °C for 16h or until all the starting carbamate was consumed. Water was added to the mixture and the product was extracted with EtOAc (2x25 mL). The combined organic extracts were washed with brine solution, dried (Na₂SO₄) and concentrated to yield crude product, which was purified by column chromatography to yield the target compound.

[0119] General Method B: To a suspension of the amine (usually 0.67 mmol) in EtOAc (2 mL) was added aqueous 1N NaOH. The reaction mixture was cooled to 0 °C and treated with isopropenyl chloroformate (0.1 mL, 0.94 mmol) over 30 sec. The reaction mixture was stirred for 15 min at 0 °C and 1h at RT. The reaction was poured into THF-EtOAc (1:1; 40 mL) and washed with H₂O (2x10 mL) and brine (2x10 mL). The organics were dried (Na₂SO₄), concentrated and the residue purified via column chromatography or recrystallization to provide the target (prop-1-en-2-yl)carbamate. To the carbamate (usually 0.26 mmol) was added the appropriate amine (usually 0.26 mmol) in THF (2 mL) and 1-methylpyrrolidine (catalytic amount) and the reaction mixture was stirred at 60 °C for 18h. The mixture was diluted with CH₂Cl₂ (2 mL) and hexane (0.5 mL) solution, and stirred for 10 min. The resultant solid was filtered and dried.

[0120] General Method C: To a stirring solution of the carboxylic acid (0.24 mmol) and TEA (1.2 mmol) in 1,4-dioxane (4.5 mL) at RT was added DPPA (0.29 mmol). After 30 min at -78 °C, the resulting solution was treated with isopropenyl chloroformate (3.2 mmol, 1.0 eq). After another 30 min at -78 °C, the completed reaction was diluted with 3M HCl, warmed to RT and extracted with EtOAc (2x). The combined organics were washed with H₂O (1x), satd. NaHCO₃ (1x), and brine (1x), dried (MgSO₄), filtered and concentrated *in vacuo* to afford the target prop-1-en-2-yl carbamate which was used as is, purified by silica gel chromatography or recrystallized.

Section 4. Biological Data

c-ABL kinase (Seq. ID no. 1) assay

[0253] Activity of c-ABL kinase (Seq. ID no. 1) was determined by following the production of ADP from the kinase reaction through coupling with the pyruvate kinase/lactate dehydrogenase system (e.g., Schindler, *et al.* Science (2000) 289, 1938-1942). In this assay, the oxidation of NADH (thus the decrease at A_{340nm}) was continuously monitored spectrophotometrically. The reaction mixture (100 µl) contained c-ABL kinase (1 nM, c-ABL from deCode Genetics), peptide substrate (EAIYAAPFAKKK, 0.2 mM), MgCl₂ (10 mM), pyruvate kinase (4 units), lactate dehydrogenase (0.7 units), phosphoenol pyruvate (1 mM), and NADH (0.28 mM) in 90 mM Tris buffer containing 0.2 % octyl-glucoside and 3.5 % DMSO, pH 7.5. Test compounds were incubated with c-ABL (Seq. ID no. 1) and other reaction reagents at 30 °C for 2 h before ATP (500 µM) was added to start the reaction. The absorption at 340 nm was monitored continuously for 2 hours at 30 °C on Polarstar Optima plate reader (BMG). The reaction rate was calculated using the 1.0 to 2.0 h time frame. Percent inhibition was obtained by comparison of reaction rate with that of a control (i.e. with no test compound). IC₅₀ values were calculated from a series of percent inhibition values determined at a range of inhibitor concentrations using software routines as implemented in the GraphPad Prism software package.

c-ABL kinase (Seq. ID no. 2) assay

[0254] Activity of T315I c-ABL kinase (Seq. ID no. 2) was determined by following the production of ADP from the kinase reaction through coupling with the pyruvate kinase/lactate dehydrogenase system (e.g., Schindler, *et al.* Science (2000) 289, 1938-1942). In this assay, the oxidation of NADH (thus the decrease at A_{340nm}) was continuously monitored spectrophotometrically. The reaction mixture (100 µl) contained c-ABL kinase (4.4 nM, M315I c-ABL from deCode Genetics), peptide substrate (EAIYAAPFAKKK, 0.2 mM), MgCl₂ (10 mM), pyruvate kinase (4 units), lactate dehydrogenase (0.7 units), phosphoenol pyruvate (1 mM), and NADH (0.28 mM) in 90 mM Tris buffer containing 0.2 % octyl-glucoside and 1 % DMSO, pH 7.5. Test compounds were incubated with T315I c-ABL (Seq. ID no. 2) and other reaction reagents at 30 °C for 1 h before ATP (500 µM) was added to start the reaction. The absorption at 340 nm was monitored continuously for 2 hours at 30 °C on Polarstar Optima plate reader (BMG). The reaction rate was calculated using the 1.0 to 2.0 h time frame. Percent inhibition was obtained by comparison of reaction rate with that of a control (i.e. with no test compound). c-KIT kinase (Seq. ID no. 9) assay

[0255] Activity of c-KIT kinase (Seq. ID no. 9) was determined by following the production of ADP from the kinase reaction through coupling with the pyruvate kinase/lactate dehydrogenase system (e.g., Schindler, et al. Science (2000) 289, 1938-1942). In this assay, the oxidation of NADH (thus the decrease at A340nm) was continuously monitored spectrophotometrically. The reaction mixture (100 μ l) contained c-KIT (cKIT residues T544-V976, from ProQinase, 5.4 nM), polyE4Y (1 mg/ml), MgCl₂ (10 mM), pyruvate kinase (4 units), lactate dehydrogenase (0.7 units), phosphoenol pyruvate (1 mM), and NADH (0.28 mM) in 90 mM Tris buffer containing 0.2 % octyl-glucoside and 1 % DMSO, pH 7.5. Test compounds were incubated with C-MET (Seq. ID no. 9) and other reaction reagents at 22 °C for < 2 min before ATP (200 μ M) was added to start the reaction. The absorption at 340 nm was monitored continuously for 0.5 hours at 30 °C on Polarstar Optima plate reader (BMG). The reaction rate was calculated using the 0 to 0.5 h time frame. Percent inhibition was obtained by comparison of reaction rate with that of a control (i.e. with no test compound). IC₅₀ values were calculated from a series of percent inhibition values determined at a range of inhibitor concentrations using software routines as implemented in the GraphPad Prism software package.

c-MET kinase (Seq. ID no. 10) assay

[0256] Activity of c-MET kinase (Seq. ID no. 10) was determined by following the production of ADP from the kinase reaction through coupling with the pyruvate kinase/lactate dehydrogenase system (e.g., Schindler, et al. Science (2000) 289, 1938-1942). In this assay, the oxidation of NADH (thus the decrease at A340nm) was continuously monitored spectrophotometrically. The reaction mixture (100 μ l) contained c-MET (c-MET residues: 956-1390, from Invitrogen, catalogue #PV3143, 6 nM), polyE4Y (1 mg/ml), MgCl₂ (10 mM), pyruvate kinase (4 units), lactate dehydrogenase (0.7 units), phosphoenol pyruvate (1 mM), and NADH (0.28 mM) in 90 mM Tris buffer containing 0.25 mM DTT, 0.2 % octyl-glucoside and 1 % DMSO, pH 7.5. Test compounds were incubated with C-Met (Seq. ID no. 10) and other reaction reagents at 22 °C for 0.5 h before ATP (100 μ M) was added to start the reaction. The absorption at 340 nm was monitored continuously for 2 hours at 30 °C on Polarstar Optima plate reader (BMG). The reaction rate was calculated using the 1.0 to 2.0 h time frame. Percent inhibition was obtained by comparison of reaction rate with that of a control (i.e. with no test compound). IC₅₀ values were calculated from a series of percent inhibition values determined at a range of inhibitor concentrations using software routines as implemented in the GraphPad Prism software package.

Cell Culture

[0257] BaF3 cells (parental or transfected with the following: wild type p210 BCR-ABL and T315I p210 BCR-ABL) was obtained from Professor Richard Van Etten (New England Medical Center, Boston, MA). Briefly, cells were grown in RPMI 1640 supplemented with 10% characterized fetal bovine serum (HyClone, Logan, UT) at 37 degrees Celsius, 5% CO₂, 95% humidity. Cells were allowed to expand until reaching 80% saturation at which point they were subcultured or harvested for assay use.

Cell Proliferation Assay

[0258] A serial dilution of test compound was dispensed into a 96 well black clear bottom plate (Corning, Corning, NY). For each cell line, three thousand cells were added per well in complete growth medium. Plates were incubated for 72 hours at 37 degrees Celsius, 5% CO₂, 95% humidity. At the end of the incubation period Cell Titer Blue (Promega, Madison, WI) was added to each well and an additional 4.5 hour incubation at 37 degrees Celsius, 5% CO₂, 95% humidity was performed. Plates were then read on a BMG Fluostar Optima (BMG, Durham, NC) using an excitation of 544 nM and an emission of 612 nM. Data was analyzed using Prism software (Graphpad, San Diego, CA) to calculate IC₅₀'s.
