(54) Title: A METHOD AND PROCESS FOR DESIGN OF INTEGRATED CIRCUITS USING REGULAR GEOMETRY PATTERNS TO OBTAIN GEOMETRICALLY CONSISTENT COMPONENT FEATURES
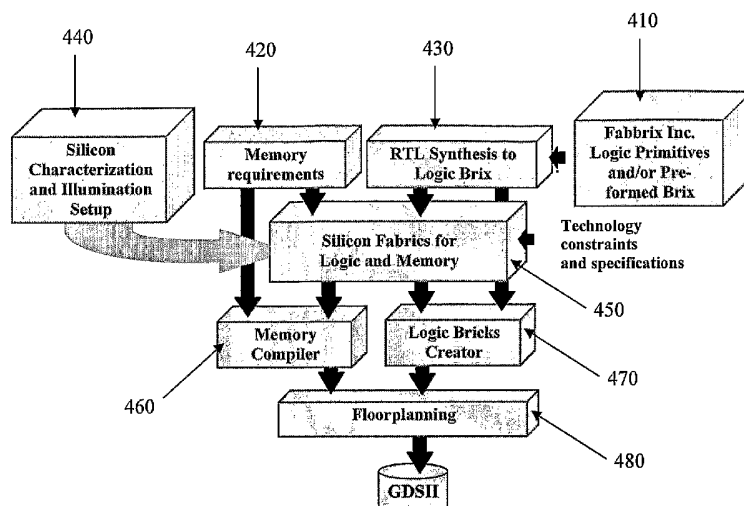

(57) Abstract: The invention provides a method and process for designing an integrated circuit based on using the results from both 1) a specific set of silicon test structure characterizations and 2) the decomposition of logic into combinations of simple logic primitives, from which a set of logic bricks are derived that can be assembled for a manufacturable-by-construction design. This implementation of logic is compatible with the lithography settings that are used for implementation of the memory blocks and other components on the integrated circuit, particularly by implementing geometrically consistent component features. The invention provides the ability to recompile a design comprised of logic and memory blocks onto a new geometry fabric to implement a set of technology-specific design changes, without requiring a complete redesign of the entire integrated circuit.

A METHOD AND PROCESS FOR DESIGN OF INTEGRATED CIRCUITS
USING REGULAR GEOMETRY PATTERNS TO OBTAIN GEOMETRICALLY
CONSISTENT COMPONENT FEATURES

PRIORITY CLAIM

[0001]   This application claims priority to U.S. Provisional Application No.
60/625,342 entitled "A Method and Process for Design of Integrated Circuits Using Regular
Geometry Patterns" filed on November 4, 2004, and which is expressly incorporated by reference
herein.

BACKGROUND

FIELD OF THE INVENTION

[0002]   The present invention relates to a method and process for design of integrated
circuits using regular geometry patterns to obtain component features that are geometrically
consistent and, more particularly to the design of integrated circuits that have memory cells and
logic components using regular geometry patterns to obtain geometrically consistent component
features.

BACKGROUND OF THE INVENTION

[0003]   The active devices (transistors) and metal interconnecting layers for an
integrated circuit (IC) are typically created by printing geometrical shapes onto a mask, then
using a lithography process to translate said shapes onto layers of materials that define the shapes
for the corresponding fabrication steps. Upon completion of multiple stages of said steps,
including the layering of materials, three dimensional devices and interconnecting layers are
ultimately produced to form the integrated circuit. As feature sizes are scaled well below the
wavelengths of the light that are used for this lithography, the shapes of the mask geometries
must be drawn substantially different from the shapes that are to be defined on the fabrication
materials due to the need for resolution enhancement techniques (RETs) and optical proximity
correction (OPC).

[0004]   In further detail, as illustrated in Figure 1, the traditional design flow for an Application-Specific Integrated Circuit (ASIC) that contains both memory cells/blocks and logic gates/blocks is illustrated. The memory bit-cells are carefully designed in silicon one or more times for a specific technology, then compiled into a memory block using software that is referred to as a memory compiler. The printability of the memory cells are controlled for compilation of memory blocks of any size by the design and silicon testing of bit-cells that are surrounded by identical neighboring bit-cells. To ensure proper control of the lithography process, the number of neighborhood cells required for a test-run of silicon is based on the silicon technology, the illumination controls and equipment used for lithography, and the manufacturing processes.

[0005]   In contrast to the memory block design, referring to the left side of Fig. 1, the traditional design flow for the logic portion of an IC, particularly an ASIC, corresponds to: designing a library of cells in test runs of silicon; characterizing the cells in terms of their layouts and performances; configuring interconnections of cells as part of technology mapping step for logic synthesis; and arranging as part of the physical design step to create a logic block.

[0006]   In this traditional flow, the lithography is controlled by post-processing of the geometrical patterns that are generated for physical design during the step that we refer to as the manufacturing interface in Fig. 1. It is important to note that the logic gates are designed without regular geometry pattern constraints, and their boundaries with neighboring cells in the final layout are not constrained for printability, and as such the manufacturing interface may not be able to ensure a high yield in terms of properly functioning (both logical operation correctness and performance) integrated circuits.

[0007]   Test structures are presently used to evaluate the printability of fundamental components, circuit primitives, and/or design rules, however these existing methodologies do not otherwise restrict the allowable geometry patterns from which the IC is constructed.

[0008]   What is needed is a means of fabricating silicon test structures to define uniform patterns of geometrical shapes that establish the underlying physical regularity from which the electronic devices and associated interconnects may be constructed.

SUMMARY OF THE INVENTION

[0009]   The invention provides a method and process for designing an integrated circuit based on using the results from both 1) a specific set of silicon test structure characterizations and 2) the decomposition of logic into combinations of simple logic primitives, from which a set of logic bricks are derived that can be assembled for a manufacturable-by-construction design. This implementation of logic is compatible with the lithography settings that are used for implementation of the memory blocks and other components on the integrated circuit, particularly by implementing component features that are geometrically consistent, preferably for a specific lithography setup. The invention provides the ability to recompile a design comprised of logic and memory blocks onto a new geometry fabric to implement a set of technology-specific design changes, without requiring a complete redesign of the entire integrated circuit.

BRIEF DESCRIPTION OF THE DRAWINGS

[00010]   These and other aspects and features of the present invention will become apparent to those of ordinary skill in the art upon review of the following description of specific embodiments of the invention in conjunction with the accompanying figures, wherein:

[00011]   Fig. 1 illustrates a traditional design flow for an integrated circuit;

[00012]   Fig. 2 illustrates an exemplary fabric according to the present invention;

[00013]   Fig. 3 illustrates the usage of controlled boundaries of logic functions so that common geometrical patterns appear among neighboring logic bricks according to the present invention; and

[00014]   Fig. 4 illustrates the design flow according to the present invention for designing an integrated circuit using regular geometry patterns according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

[00015]   This invention provides a method and process by which silicon test structures are first fabricated to define uniform patterns of geometrical shapes. These uniform patterns of geometrical shapes are used to define the underlying fabric from which the component features for the electronic devices and associated interconnect structures on the integrated circuit are derived such that they are geometrically consistent, preferably for a specific lithography setup.

The invention provides a means whereby these uniform patterns of geometrical shapes (also referred to as regular patterns, or regular geometrical patterns) will be optimized to match the corresponding settings for the illumination controls that will be used for lithography. The invention also provides a novel method and means by which illumination controls are determined by the requirements of the uniform pattern printing, as well as the printing of the geometrical patterns for memory cells and other integrated circuit components that are derived from the uniform patterns. The invention further provides the ability to recompile a design comprised of logic and memory blocks onto a new geometry fabric to implement a set of technology-specific design changes, without requiring a complete redesign of the entire integrated circuit.

[00016]   One aspect of the invention is that the number of patterns that exist and which are used to establish the underlying physical regularity of the component features is purposefully kept to a small number, such that the number of patterns is typically less than 100-200, and, put another way, for complex designs, will typically be orders of magnitude less in number than using patterns as used with conventional standard cell libraries.   And for each of the patterns that exist, there is associated with that pattern the corresponding settings for the illumination controls that will be used for lithography.   As such, due to the limited number of patterns within the memory blocks or logic bricks as described hereinafter, the overall number of patterns that will exist and require preprocessing (such as OPC and RET as discussed previously) is substantially smaller, thus causing a significant decrease in the amount of computing power needed for preprocessing, since the amount of computing power needed to properly optimize the shape and size of the illuminator for each different pattern is very significant, reducing the number of patterns for which such optimization is needed is a significant advance. Furthermore, greater attention can be paid to optimizing the OPC and RETs for the reduced number of patterns such that the resulting circuit components are constructed with superior performance in terms of significantly reduced process variations.

[00017]   The invention provides that the derived uniform patterns of geometrical shapes are used to specify an underlying fabric of regular geometry. All the geometrical shapes of the component features for all devices and interconnections are ultimately derived from combinations of these patterns. The resulting component features can be viewed in a number of manners, such as, for example, features obtained from removing segments from the fabric to derive a unique pattern on various layers which produces a specific circuit component, or building up such a component feature. In a preferred embodiment, the resulting geometrical shapes for a particular mask layer that correspond to the component features are derived by a process that is equivalent

to removing selected segments from the fabric that is based on the patterns and adding "vias" in restricted locations to connect neighboring layers, as is illustrated in Figure 2, with the fabric 200 containing different layers, with each layer thereby having geometrically consistent component features therein. All of the geometric shapes on a layer are at a fixed pitch, and have a fixed width for the horizontal and vertical directions respectively. Therefore the fabric can be represented by a fully connected graph, or grid. Geometrically consistent component features are achieved since they are optimized to match the corresponding settings for the illumination controls that will be used for lithography. In a particular aspect, similarities between regular geometric patterns can have associated therewith similarities in the settings for illumination controls.   It is noted that the layers that are above the substrate layer are typically referred to, and are herein referred to, as being the fabric, with the doped substrate layer not being considered part of the fabric. In one preferred embodiment, the removal of certain fabric portions using patterns and via connections between layers thereby create a brick 300 with devices and interconnections that implement predetermined functions, while implicitly satisfying the requirements for printability using the aforementioned illumination settings, though other manners of creating a series of uniform bricks can also be implemented. With this preferred embodiment, the fabric itself is not viewed as having unique patterns, since it is uniform, and loosely associated with the design rules. The bricks, however, can be defined by a set of unique patterns, as formed by removing segments of the fabric.

[00018]   As one example of this invention, a portion of a digital integrated circuit is formed by mapping a restricted set of logic primitives (e.g. nand, nor, invert and multiplex) onto areas of regular geometric fabrics, thereby forming the patterns on the layer that result in the component features for devices and interconnections that will be perform the intended logic functions, with different combinations of logic functions being used to instantiate different logic bricks. In such cases, the logic primitives are represented by subset patterns which are based on the underlying uniform patterns which define the fabric. The physical instantiations of the different logic function combinations in silicon are referred to as logic bricks, and the concept of logic bricks is known. The logic bricks according to the present invention, however, further distinguish from logic bricks as has been known in that they are formed using common geometric patterns that have been chosen for printability and which thus result in the consistent component features of the devices and interconnections of a particular brick. As such, the brick sizes and patterns used within the bricks are optimized for compatibility with the illumination control settings that will be used for the lithography of the bricks, as well as the lithography of the other

IC components, such as memory cells. As such, different logic bricks will contain different combinations of logic functions, implemented by different devices, but the physical patterns that make up the devices and interconnections in different logic bricks are consistent with the underlying uniform fabric, and therefore consistent the illumination setup.

[00019] Also, the physical boundaries of the logic bricks are controlled so that common geometrical patterns appear among neighboring logic bricks that are printed, as is illustrated in Figure 3. This is significant, since in the implementation of a typical integrated circuit, some small number of different logic bricks will be combined in order to produce the functionality needed. So, for example, in a particular integrated circuit design, there may be ten different logic bricks that are used, with each of the 10 logic bricks used some integer number of times, and, preferably, all of the different logic bricks being formed from the same fabric (and thereby resulting in a minimal number of additional unique patterns within different bricks to begin with). In addition, given that the at the physical boundary of each brick there are common geometrical patterns corresponding to component features, this even further reduces the overall number of unique patterns that will require optimizations such as OPC that are computationally large in terms of overall computer power needed, as mentioned above. Accordingly, in addition to having unique patterns within different bricks that are based upon regular patterns of the fabric, the existence of common geometrical patterns at the physical boundary of each brick further reduces the preprocessing computations that are necessary.

[00020] This invention also provides that once the physical design of a brick has been established based on the illumination controls, it can be evaluated for printability in silicon independently of the other bricks that will ultimately be printed in its neighborhood. Such evaluation is not needed in many instances, since the various bricks in a design preferably come from a common fabric. Nonetheless, typically the first time a brick is implemented it will be evaluated, and, subsequently, when modifications that are more than small changes to certain settings, as described hereinafter, are made, it can be prudent to perform another evaluation This method and process invention for logic design and implementation is therefore analogous to the process of memory block design, and in stark contrast to the process by which application-specific integrated circuits (ASICs) are built using standard cells.

[00021] The method and process for designing integrated circuits by the invention described herein is summarized in Fig. 4. In this method and process, the silicon characterization is performed for a compatible set of illumination controls that will define the geometry shapes for the memory bit-cells and for the regular geometry patterns for the logic circuits that are used to

operate upon the fabric. The invention provides concurrent design of the regular geometric patterns that are used to form the component features for the memory and the logic, a critical innovative step useful in producing high yield for integrated circuits that are designed in extreme scaled CMOS.

[00022]   The memory bit-cells are designed in a manner similar to the traditional flow, but they now additionally considers the geometry pattern requirements (and therefore the illumination control settings). An example of such a requirement would be the determination of the regular fabric required for control of process variations that impact effective channel length for the transistors that define the logic, which could in turn define the leakage currents for the devices, with the channel length being a component feature in this example. This method of design allows the application-specific technology targets to become part of the system level design process, as shown in Fig. 4.

[00023]   Following the methodology described in Fig. 4, described in detail hereinafter, an aspect of this invention is that the design of a block of logic gates can now be created analogously to the construction of a memory block. Once the fabric is derived for a particular technology with technology-specific settings (e.g. effective channel length), just as is done for a specific bit-cell for memory, the logic primitives are mapped to shapes that are consistent with or derived from the regular fabric patterns. In this invention, the physical patterns that comprise a small logic function are represented by logic bricks. Note that bricks can be of various sizes, and while somewhat analogous to "cells" used for standard cell design, bricks are very distinct in terms of their geometrical regularity.

[00024]   For memory block design, individual bit-cells are fabricated in test runs of silicon with neighboring bit-cells to mimic their environment on an IC. For standard cells, it is impractical to construct test chips that mimic all possible environments for all cells in a standard cell library. The invention provides that once the regular geometry patterns that are used to form the component features are derived from the silicon test structures, the regular geometry patterns that are used to form the component features for the bricks and their environment are sufficiently understood so that lithography can be controlled in a manner analogous to that which is possible for memory compilation.

[00025]   Referring to Fig. 4, the silicon test structures and the technology-specific design requirements are used to derive the regular geometry patterns that are used to form the component features for both the logic components and the memory components in a manner in which they are geometrically consistent with each other as shown in the functional step 450

labeled "Silicon Fabrics for Logic and Memory". These regular geometry patterns that are used to form the component features for both the logic components and the memory components are obtained using information on the technology constraints and specifications, as well as from the silicon characterization and illumination controls input step 440. From these regular geometry patterns that are used to form the component features, the logic bricks are compiled in step 470 from a combination of the fabric constraints and the logic primitives or preformed brick component features that are obtained as shown at step 410 and synthesized as shown at step 430. Similarly, the memory block (or blocks in the case of two or more different types of memories on the same IC being used) is compiled in step 460, using regular geometry patterns that are used to form the component features from the silicon fabrics for logic and memory step 450, as well as information obtained from the memory requirements input step 420. Thereafter, the traditional floor planning of the memory blocks and regular logic fabric blocks step 480 can occur, so that the results can be stored for subsequent use.

[00026]   Note that the bricks can be unique for each logic function required as determined from synthesis, as long as the physical creation of each brick is done so while maintaining the required geometrical regularity. Bricks can also be derived from the design specifications (as described by the design netlist) of one or more applications whereby each set of regular geometry patterns which form bricks can be slightly modified to "configure" the bricks for a specific logic function. One example of such configuration could be the insertion of vias to connect neighboring layers of metal to form a connection, thereby configuring the logic to perform a specific function.

[00027]   A feature of this invention is that, unlike standard cells, for which cells are designed and tested in silicon for specific technology settings (e.g. effective channel lengths), the logic representations for bricks can be mapped to new regular fabrics to implement new technology settings without requiring the explicit characterization of the bricks in silicon. This is a powerful capability for allowing technology-specific adjustments to be made to a design. For example, a lower leakage design can be derived for a specific bricks design whereby the incurred area and performance can be estimated prior to fabrication based on the physical changes in the bricks.

[00028]   Another implementation of the invention uses an already existing memory bit-cell block, which block already has established its lithography settings and optimizations. The lithography settings and optimizations, along with the regular geometric patterns that result in the geometrically consistent memory cell features that exist in the memory bit-cell block, can be used

for the regular geometric patterns are used to obtain the geometrically consistent features within the logic bricks.

[00029]   In an implementation that is a bit different than that described above, for an already existing memory bit-cell block, which block already has established its lithography settings and optimizations, the lithography settings and optimizations, preferably along with the regular geometric patterns that result in the geometrically consistent memory cell features that exist in the memory bit-cell block, can be used to derive a geometrically consistent fabric for the logic, from which the compatible logic bricks can be constructed.

[00030]   As another example of application specific process optimization, since the logic brick/memory block design will have only a limited number of patterns that are shared between them, it is easier to optimize process parameters, such as scanner settings used for lithography. Therefore, given a logic brick/memory block design, one can actually explore alternative process settings and be able to easily assess the impact on performance and design quality using the available simulation tools.

[00031]   One optimization example that will change the component features based upon changing a parameter is changing the pitch of the poly silicon lines (and corresponding process settings) that define the size and locations of the transistors to achieve a different trade-off between OFF (leakage) and ON (which defines transistor speed) currents and design density (area). This allows one to adjust a finalized layout to meet an originally intended power/performance/area objective that is impossible to optimize a priori.   Also, as the process evolves for a specific design in a specific technology, new advances in the process can be easily introduced in the design (i.e. design can keep up with advances in the current process). The existing logic brick/memory block design can be adjusted to accommodate those process changes without requiring a redesign.

[00032]   The present invention enables this adjustment without redesign because more optimal and accurate OPC (optical proximity correction) models can be applied to the limited number of patterns that are present in the design. For example, metal line-ends near thick metals (such as power strips) require modification of the power strip in order to print within an acceptable budget. Conventional OPC, which is not context aware, could not make these kind of corrections. With regular fabrics being used with logic bricks, changing the underlying grid spacings allows correction of the OPC because of a small number of unique patterns, and it is a much more predictable change.

[00033] Further, if a given pattern in a particular brick is found not provide good yield, it can be readily be replaced by a more manufacturable pattern with direct assessment of the area cost. For example, in a standard cell design, two metals line-ends at close proximity cannot be easily reproduced if they are in a dense region of metal. Thus, this specific pattern would have to be removed, and replaced with a pattern containing the line-ends in a more isolated region of metal.

[00034] For metal layers which connect and define the brix (m1/m2), for a given pitch, the width/space can be modified to obtain the desired yield/performance point. For example, decreasing the width of the lines, which will reduce the parasitic capacitances (to substrate & cross-coupled), will thus obtain better performance, at the expense of being able to fill-in thinner gaps in the dielectric (i.e. yield losses due to an open line). Of course this can be applied in reverse, trading off larger capacitance for less likelihood of an open (a failed manufacturing of a line which results in it being an open circuit and not connected).

[00035] And with respect to line-ends, the invention allows modifying the extension of metal over a via/contact at the expense of the spacing b/w metals. This allows a trade off of yield due to metal short defects vs. not enough via coverage.

[00036] Although the present invention has been particularly described with reference to embodiments thereof, it should be readily apparent to those of ordinary skill in the art that various changes, modifications and substitutes are intended within the form and details thereof, without departing from the spirit and scope of the invention. Accordingly, it will be appreciated that in numerous instances some features of the invention will be employed without a corresponding use of other features. Further, those skilled in the art will understand that variations can be made in the number and arrangement of components illustrated in the above figures. It is intended that the scope of the appended claims include such changes and modifications.

WHAT IS CLAIMED IS:

1.   A method of representing a portion of an integrated circuit design of an integrated circuit
device, the method comprising the steps of:

        providing a memory cell representation , the memory cell representation representing a
memory cell having memory cell components with geometrically consistent memory cell
component features; and

        providing a plurality of logic brick representations, each of the logic brick representations
representing a different logic structure having logic components with geometrically consistent
logic component features, the geometrically consistent memory cell component features and the
geometrically consistent logic component features being geometrically consistent with each other.

2.   The method according to claim 1 further including the step of using the plurality of
memory cell representations and the plurality of logic brick representations to create the masks
for the integrated circuit device.

3.   The method according to claim 2 wherein the plurality of memory cell representations and
the plurality of logic brick representations have associated therewith a common set of
illumination control settings used during the fabrication of the memory cell component features
and the logic component features.

4.   The method according to claim 3 wherein sizes of the geometrically consistent memory
cell component features and the geometrically consistent logic component features are
substantially less than wavelengths of light used in a lithography process during fabrication of the
integrated circuit device.

5.   The method according to claim 1 wherein the plurality of memory cell representations and
the plurality of logic brick representations have associated therewith a common set of
illumination control settings used during the fabrication of the memory cell component features
and the logic component features.

6.   The method according to claim 1 wherein sizes of the geometrically consistent memory

cell component features and the geometrically consistent logic component features are substantially less than wavelengths of light used in a lithography process during fabrication of the integrated circuit device.

7.   The method according to claim 1 wherein the plurality of geometrically consistent features for the memory cell representations and the plurality of geometrically consistent features for the logic brick representations are designed concurrently.

8.   The method according to claim 1 wherein the step of providing provides a second memory cell representation that represents second memory cells of the previously compiled integrated circuit design, the second memory cells having second memory cell components with the geometrically consistent component features.

9.   The method according to claim 1 wherein the geometrically consistent memory cell component features and the geometrically consistent logic component features are unique patterns that derive from a set of uniform patterns of geometrical shapes.

10.   The method according to claim 9 wherein a number of the patterns in the set of uniform patterns of geometrical shapes is less than 200.

11.   A method of recompiling a previously compiled integrated circuit design having memory cells and logic structures to obtain a variant design having the memory cells and the logic structures comprising the steps of:

        reading in layouts of geometrically consistent component features used in the previously compiled integrated circuit design, the layouts of the geometrically consistent component features being geometrically consistent with each other and used in forming the memory cell representation and logic brick representations of the previously compiled design, wherein

        the memory cell representation representing the memory cells of the previously compiled integrated circuit design, the memory cells having memory cell components with the geometrically consistent component features,

        the logic brick representations representing the logic structures of the previously compiled integrated circuit design, each logic structure having logic components with the geometrically consistent component features,

concurrently adjusting at least one parameter of the geometrically consistent component features of the layouts based on one of technology information and circuit design and performance objectives to obtain updated layouts;

using the updated layouts to complete the variant design without changing a relative ordering of the memory cells and the logic structures relative to each other and without changing a location of the memory cells and the logic structures relative to each other.

12.   The method according to claim 11 wherein the step of concurrently adjusting the at least parameter of the geometrically consistent component features occurs without determining which geometrically consistent component features are memory cell component features and which are geometrically consistent logic component features.

13.   The method according to claim 11 wherein the step of concurrently adjusting obtains updated memory cell representations and updated logic brick representations, wherein the updated memory cell representations represent the memory cells having the memory cell components with updated geometrically consistent memory cell component features and the updated logic brick representations representing the logic components with updated geometrically consistent logic component features,

14.   The method according to claim 13 wherein the updated geometrically consistent memory cell component features and the updated geometrically consistent logic component features are used to adjust all of the memory cells and all of the logic structures that are used in the variant design.

15.   The method according to claim 11 wherein the step of using the updated layout to complete the variant design includes the step of recharacterizing the memory cells and the logic structures.

16.   The method according to claim 17 wherein the step of recharacterizing includes the step of recharacterizing timing characteristics of the variant design.

17.   The method according to claim 11 wherein the layouts of geometrically consistent component features are also used by a second memory cell representation that represents a second

memory cell representation representing second memory cells of the previously compiled integrated circuit design, the second memory cells having second memory cell components with the geometrically consistent component features.

18.   The method according to claim 11 using the updated layouts to complete the variant design includes the step of using the updated layouts to create the masks for the integrated circuit device.

19.   The method according to claim 18 wherein the updated layouts include a plurality of updated memory cell representations and a plurality of updated logic brick representations that have associated therewith a common set of illumination control settings used during the fabrication of the variant design.

20.   The method according to claim 19 wherein sizes of updated geometrically consistent memory cell component features and updated geometrically consistent logic component features are substantially less than wavelengths of light used in a lithography process during fabrication of the variant design.

21.   A method of using memory cell illumination control levels associated with memory cell fabrication to fabricate additional logic bricks on the same integrated circuit device comprising the steps of:
        reading in a memory cell representation representing the memory cells of an integrated circuit design, the memory cells having memory cell components with geometrically consistent memory cell component features,
        determining the geometrically consistent component features of the geometrically consistent memory cell component features;
        providing a plurality of logic brick representations, each logic brick representation representing a different desired logic structure and having logic components with logic component features;
        associating the geometrically consistent component features with each of the logic component features, so that the logic component features are geometrically consistent with the memory cell component features.

22.   The method according to claim 21 further including the step of using the plurality of memory cell representations and the plurality of logic brick representations to create the masks for the integrated circuit device.

23.   The method according to claim 22 wherein the plurality of memory cell representations and the plurality of logic brick representations have associated therewith a common set of illumination control settings used during the fabrication of the memory cell component features and the logic component features.

24.   The method according to claim 23 wherein sizes of the geometrically consistent memory cell component features and the geometrically consistent logic component features are substantially less than wavelengths of light used in a lithography process during fabrication of the integrated circuit device.

25.   The method according to claim 21 wherein the plurality of memory cell representations and the plurality of logic brick representations have associated therewith a common set of illumination control settings used during the fabrication of the memory cell component features and the logic component features.

26.   The method according to claim 21 wherein sizes of the geometrically consistent memory cell component features and the geometrically consistent logic component features are substantially less than wavelengths of light used in a lithography process during fabrication of the integrated circuit device.

27.   The method according to claim 21 wherein the geometrically consistent memory cell component features and the geometrically consistent logic component features are unique patterns that derive from a set of uniform patterns of geometrical shapes.

28.   The method according to claim 27 wherein a number of the patterns in the set of uniform patterns of geometrical shapes is less than 200.

29.   A method of creating a plurality of logic brick representations used in representing different portion of an integrated circuit design, the method comprising the steps of:

obtaining a set of uniform patterns of geometrical shapes based upon regular patterns from a memory cell representation; and

determining a plurality of logic brick representations, each logic brick representation representing a different desired logic structure and having logic components that have geometrically consistent component features that are unique patterns that derive from the set of uniform patterns of geometrical shapes.

30.   The method according to claim 29 wherein the step of using uses a same fabric for each of the logic brick representation.

31.   The method according to claim 30 wherein the step of determining the plurality of logic brick representations determines as the same fabric a logic fabric that is geometrically consistent with the set of uniform patterns of geometrical shapes.

32.   The method according to claim 31 wherein illumination control settings used on the logic fabric are obtained from memory illumination control settings used with the uniform patterns of geometrical shapes based upon regular patterns from the memory cell representation.

33.   The method according to claim 29 wherein the step of determining the plurality of logic brick representations differ only in via placements therein.

34.   The method according to claim 33 further including the step of using the plurality of logic brick representations in designing an integrated circuit device.

35.   The method according to claim 34 further including the step of using the plurality of logic brick representations to create the masks for the integrated circuit device.

36.   The method according to claim 35 wherein the plurality of logic brick representations have associated therewith a common set of illumination control settings used during the fabrication of the geometrically consistent logic component features.

37.   The method according to claim 36 wherein sizes of the geometrically consistent logic component features are substantially less than wavelengths of light used in a lithography process during fabrication of the integrated circuit device.

38.   The method according to claim 36 wherein the illumination control settings are obtained from memory illumination control settings used with the uniform patterns of geometrical shapes based upon regular patterns from the memory cell representation.

39.   The method according to claim 29 wherein the plurality of logic brick representations have associated therewith a common set of illumination control settings used during the fabrication of the geometrically consistent logic component features.

40.   The method according to claim 29 wherein sizes of the geometrically consistent logic component features are substantially less than wavelengths of light used in a lithography process during fabrication of the integrated circuit device.

41.   The method according to claim 35 wherein the geometrically consistent logic component features are made using a pattern or combinations of patterns obtained from a set of uniform patterns of geometrical shapes.

42.   The method according to claim 41 wherein a number of the patterns in the set of uniform patterns of geometrical shapes is less than 200.
