An article having a textured surface and a method for manufacturing such an article is provided. The article comprises a polymeric layer coated on at least a portion of the article, a plurality of cavities formed in the polymeric layer, wherein each cavity in the plurality of cavities have a size between about 50 microns to about 2000 microns, and wherein a majority of the plurality of cavities have encircling perimeter ridges, and a plurality of channels formed in the polymeric layer between the encircling perimeter ridges.
TEXTURED SURFACE ARTICLES AND METHOD OF MAKING

CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application is a continuation application of U.S. application Ser. No. 11/639,017, filed Dec. 14, 2006 and published as U.S. Patent Application Publication No. 2007/0118967, which is a continuation application of U.S. application Ser. No. 10/882,916, filed Jun. 30, 2004 and issued as U.S. Pat. No. 7,771,644, which claims the benefit and priority of U.S. Provisional Application No. 60/484,602, filed Jul. 2, 2003, the disclosures of each of which are hereby incorporated in their entirety by reference thereto.

BACKGROUND

Field of the Invention

[0002] The present invention relates to an article with a textured surface and methods for making the textured surface.

Description of the Related Art

[0003] Articles such as unsupported gloves are manufactured by dipping glove formers shaped like hands into tanks of liquid latex and admixed chemicals. The latex may contain vulcanization agents that are used to cure the rubber, and a dry rubber film is produced. The formers are first precoated with a coagulant to gel the latex and to facilitate the subsequent removal of the glove from the former. The precoated formers are then dipped in the tanks of chemicals necessary to make the gloves. While still on the formers, the latex gloves also go through one or more rinses to leach out proteins and residual chemicals. The wet gel is dried and cured in a heated oven and the latex glove cures on the former before they are reversed stripped off the former, packaged, and/or sterilized. The inside surface of the stripped glove is smooth whilst the outside surface of the glove takes the impression of the texture from the former.

[0004] Supported gloves are manufactured by dip coating a supporting liner dressed on a glove former. The inside of the glove can be made of a knit material, a non woven fabric or other suitable material. After drying and curing in a heated oven the glove is removed from the former but not reversed hence a smooth outside surface of the glove results from the latex dip coating process. Alternatively, supported gloves can be made by dip coating the supporting liner with a layer of foamed latex material. Prior art gloves include dip coating with a foamed latex material that is unevenly applied to provide texture, but this surface levels out in the heating and curing process, leaving a closed cellular surface structure with a smooth surface layer.

[0005] Smooth layers of latex create problems with the wearer's ability to grip objects, especially when wet. The prior art includes unsupported gloves made using formers having embossed patterns designed to improve the wearer's grip. These patterns create designs on the finished glove product, however, they contribute little to improving grip and are primarily aesthetic. Additionally, the prior art shows that post-processing of the gloves to remove excess surfactants from the latex by washing may marginally improve the wet grip. Alternatively, surface treatment by a halogen, such as chlorine, will not only remove the surfactant but also chemically modifies the latex surface. The surface treatment provides a more chemically resistant surface that retards the rate of chemical absorption and perhaps material degradation, resulting in a marginal improvement in wet grip. In supported gloves, an overcoat of polymeric latex optionally containing rubber or mineral fillers may slightly improve grip. These processes also add to the cost of glove production and may require additional machinery.

[0006] In prior art gloves where the smooth latex is on the inside of the glove, the smooth surface is in close contact with the skin and it does not absorb sweat. This creates a clammy feeling on the wearer's hands. The prior art has included cotton flock on the inside of unsupported gloves to aid in sweat absorption, yet flock only absorbs small amounts of sweat.

[0007] Foam material with a closed cellular surface layer does little to aid circulation of air inside the glove but can absorb sweat. Also, a foam material on the outside of either unsupported or supported gloves has a closed cellular surface layer that does little to enhance the ability to grip wet or slippery objects.

[0008] It is therefore desirable to have a glove with a textured surface coating that is easily produced in the normal course of glove manufacture. A glove of this type would improve grip, such as wet/oil grip, when introduced to the outside of the glove. When included on the inside of the glove a textured surface would increase sweat absorption and reduce the degree of direct skin contact hence reducing the clammy feeling against the skin. It is therefore desirable to have a foam material layer with an open cellular structure with a textured surface.

SUMMARY

[0009] There is provided, in accordance with the principles of the present invention, an article having a textured surface and a method for manufacturing such an article is provided. The article comprises a polymeric layer, a plurality of cavities formed in the polymeric layer, wherein each of the plurality of cavities is surrounded by ridges of the polymeric layer material, the plurality of cavities and the ridges in the polymeric layer forming the textured surface over at least a portion of the article. The plurality of cavities have a size between about 50 microns to about 2000 microns, and a majority of the plurality of cavities are fully surrounded by ridges.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] FIG. 1 is a photograph of a plan view of a textured surface coating in a glove made according to one embodiment of the present invention.

[0011] FIG. 2 is a photograph of a plan view of a surface of a SOLVEX 3 7-676 nitrile glove of the prior art.

[0012] FIG. 3A illustrates a cross-sectional view of a layer with a textured surface layer 210 according to an embodiment of the present invention; FIG. 3B illustrates a cross-sectional view of a two-layer textured surface layer 310 made according to an embodiment of the present invention having a textured surface layer 310 and another layer 340; and FIG. 3C illustrates a cross-sectional view of a glove made according to an embodiment of the present invention having textured surface layer 410, and additional layers 440 and 450.
FIG. 4 illustrates a cross-sectional view of a single layer untextured SOLVEX 37-676 nitrile glove of the prior art.

FIGS. 5A to 5C show articles according to the invention. FIG. 5A illustrates a glove made from one or more textured polymeric layers; FIG. 5B shows a glove with a foamed outer textured polymeric layer; and 5C shows a glove having foamed inner textured polymeric layer.

FIG. 6A is a replica of FIG. 1, except further showing (with a box in dashed lines) the insert that is shown in blown-up view in FIGS. 6B and 6C.

FIG. 6B is a blown-up view of the indicated portion of FIG. 6A, further showing (with a box in dashed lines) the insert that is shown in blown-up view in FIG. 6D.

FIG. 6C is a blown-up view of the indicated portion of FIG. 6A, further showing cavities 50 (or reverse impressions of previously embedded particles, such as salt crystals), and elongated channels 40 (marked with white lines). The bottoms of cavities are apparent.

FIG. 6D is a schematic blown-up view of the indicated portion of FIG. 6B, further showing multiple thin, distinct ridges 20 encircling the cavities 50, and multiple elongated channels 40 between the ridges 20.

DETAILED DESCRIPTION

The present invention is directed to an article having a textured surface coating made from either nonfoamed latex or foamed latex produced by embedding discrete particles in a layer of ungelled latex. The latex layer 210 of FIG. 3A, 310 of FIG. 3B, and 410 of FIG. 3C is ideally gelled on contact with the discrete particles. The process is completed by drying and curing the glove. The discrete particles may be removed from the layer either after gelling or curing by dissolving the particles in a suitable solvent. This process leaves impressions 225, 325, or 425 where the discrete particles were embedded, resulting in a textured surface coating that can improve grip, air circulation within the glove with less direct skin contact and a degree of sweat absorption. For example, wet/oil grip is improved in the textured gloves of the present invention. Foamed material may be used in place of nonfoamed latex to produce the textured surface layer (e.g., 166 or 195), providing better grip, higher sweat absorption and a flexible layer of insulation.

The discrete particles used include, but are not limited to, various salts, including sodium chloride, calcium chloride, magnesium chloride, zinc chloride, calcium nitrate, zinc nitrate, or other soluble compounds such as sugar (sucrose). A salt that is substantially soluble in a solvent, such as water, is preferred. A preferred salt is sodium chloride. Sodium chloride has several advantages in that it is inexpensive, readily available, easily disposed of and recycled, or reused. One useful commercial preparation of sodium chloride, 99% purity, is available from BSS International Ltd., Peterborough, England. Useful mean particle sizes can range from about 50 microns to about 6000 microns. A preferred mean particle size range is from about 50 microns to about 2000 microns. While all of these salts can be used to provide a similar physical textured appearance, chloride salts provide a distinct improvement in wet/oil grip and chemical resistance of the textured surface of the present invention. A mean particle size of about 400 microns can be used to form the cavities.

A salt, such as, for example, sodium chloride, upon contact with a liquid latex used in the present invention, immediately destabilizes the latex to form a wet gel, and hence “freezes” that shape of the salt particle in the surface of the rubber. When the salt is removed a surface texture is created. This surface texture is the reverse image of the salt particle. Cavity sizes can range from about 50 microns to about 6000 microns, or from about 50 microns to about 2000 microns.

The desired texture will be controlled by the choice of discrete particle. For example, a dendritic salt will produce a multi-faceted impression because it is a many-pointed crystal. Different impression sizes will result from the particles chosen as well. Crushed salt will produce various sizes of impressions, while the very fine particles of table salt will produce a dense, more even distribution of small impressions. Mixtures or combinations of particle size can be used. The solvent used to dissolve away the discrete particles will depend on the solubility of the particles, and may be water, an acid or an alkaline compound.

According to embodiments of the present invention, gloves may be manufactured using a variety of different techniques. According to a preferred embodiment, the gloves are produced in a mass production line where a great plurality of gloves is sequentially, rapidly and consistently produced. Such a technique conveys and manipulates multiple glove formers through a series of chemical solutions and process steps to make the glove. The formers are made of porcelain, steel or plastic. According to the standard manufacturing process, gloves may be produced directly on the formers that are conveyed from one station to the next. For example, the formers are dipped into surfactants, waxes, coagulants and natural or synthetic elastomers to obtain a layer of the desired characteristics. The technique allows for altering the composition, the order of application, and the method of application of ingredients that make up the layer of the glove.

The glove may be built up from multiple dips into various substances. For example, the formers may be initially dipped into a composition of a powder free release agent and a coagulant. That release agent and coagulant dip supplies a release material for the subsequent removal of the finished glove from the formers. In addition, the coagulant material will destabilize subsequent liquid layers such as latex type elastomers.

After the release agent/coagulant dip is applied, the formers are preferably conveyed to the next station in the production line where the laminate layer (e.g., layer 340 or layer 450) is applied to the formers. The laminate layer may be comprised of a latex elastomeric dip, such as natural or synthetic rubber latex such as polyurethane, nitrile or polychloroprene. For example, various combinations and blends of latices can be used. The latices of the present invention optionally can be foamed. One useful nitrile latex is REVENEX 99G43 (Synthomer Ltd., United Kingdom). By varying the selection and composition of the latex material, the laminate layer may be varied to provide different degrees of strength, comfort, flexibility and chemical resistance. In any event, the content of the latex applied to the former will preferably be adjusted to provide protection from cuts and abrasion, liquid repellency and chemical resistance.

After the application of the laminate layer, a second coagulant dip may be applied if another laminate layer is to be applied. Additional coagulant dip and laminate layers
may be added to reach the desired degree of thickness and flexibility. After application of one or more laminate layers (e.g., layer 310, or layers 440 and 450 (a plurality of layers)), the formers are preferably passed through ovens at elevated temperatures to dry and cure and provide the final product. The gloves are then removed either manually or by an automated technique.

[0027] According to the substantially automated mass production technique described above, a great number of variations may be introduced to provide additional or different desired characteristics of the laminate in accordance with the present invention.

[0028] In one embodiment of the invention, as shown in FIG. 3B, the former is dipped to form a first layer of latex 340. This first layer of latex is then gelled and the former is dipped again to form a second layer of unaged latex 310. The viscosity of the foamed or nonfoamed latex layers of the second layer can range from about 100 cps to about 2000 cps (Brookfield). Discrete particles are then applied to the unaged second layer of latex by dipping the former into a fluidized bed of discrete particles or other mechanical means of embedding the discrete particles, for example, spraying. The fluidized bed process utilizes the suspension of salt particles (NaCl) in an air stream such that the particles behave in a manner similar to a liquid. The discrete particles are removed by dissolving with an appropriate solvent after the discrete particles have been applied or after gelling or curing of the glove to leave behind a textured surface coating substantially over the surface of the glove. For example, salt particles can be removed from the gelled surface by washing or spraying with water. Viscosity of the latex is one parameter that can be varied to achieve the desired textured effect. Textured nonfoamed layers provide the optimum durability and wet/oil grip combination.

[0029] In another embodiment of the invention as illustrated in FIG. 3C, the former is dipped into more than one layer of latex and gelled after each layer until the desired number of layers (e.g., layers 440 and 450) is achieved. The former is then dipped once more in latex and discrete particles are applied to this outermost unaged layer of latex 410 by dipping the former into a fluidized bed of discrete particles or other mechanical means of embedding the discrete particles, for example, spraying. The discrete particles are dissolved with an appropriate solvent after gelling or curing of the glove to leave behind a textured surface coating. Textured nonfoamed layers provide the optimum durability and wet/oil grip combination.

[0030] In yet another embodiment of the invention, the former is dipped to form a first layer of latex. This first layer of latex is then gelled and the former is dipped a second time in a foamed material to form a second layer. Discrete particles are then applied to the unaged layer of foamed material by dipping the former into a fluidized bed of discrete particles or other mechanical means, for example, spraying. The discrete particles are dissolved with an appropriate solvent after processing of the glove to leave behind a textured surface coating. This process creates a textured surface foam layer coating that retains an open cellular structure because the discrete particles gel the foam and hence capture the cellular structure. Additionally the reverse image of the discrete particles is captured in the surface layer following their removal by an appropriate solvent hence leaving a textured surface layer.

[0031] In another embodiment as shown in FIG. 3A, a single textured layer can be prepared according to the principles of the present invention. That is, no first or laminate layer is prepared prior to the preparation of a textured layer 210. In this embodiment, a nonfoamed or foamed layer is applied to a former. Discrete particles are then applied to the unaged layer of nonfoamed or foamed material by dipping the former into a fluidized bed of discrete particles or other mechanical means, for example, spraying. The discrete particles are dissolved with an appropriate solvent after processing of the glove to leave behind a textured surface layer.

[0032] Another embodiment of the invention includes a piece of non-latex material with a textured surface coating produced by embedding discrete particles in the outer layer of the latex overdip. For this embodiment, the former would have a layer of non-latex material applied as a support, for example, woven material or cotton flock, and be dipped in a layer of foamed or nonfoamed latex. An example of a useful woven material is a knitted liner. Discrete particles are then applied to the layer of foam material by dipping the former into a fluidized bed of discrete particles or other mechanical means of embedding the discrete particles, for example, spraying. The piece of material is then gelled or cured and the discrete particles are dissolved with an appropriate solvent to leave behind a textured surface coating. This material may then be cut apart and the pieces sewn to various glove parts to provide improved grip or absorb sweat. In embodiments of supported gloves, where latex coatings are made onto knitted linings, the first or subsequent latex layers can be subjected to texturing.

[0033] For internal linings of an unsupported glove, a substitute for traditional flocking can be made by using the textured surface against the skin. In this case a soft textured surface can be provided by applying the texture to a foamed latex. A soft feel can also be obtained by texturing a nonfoamed latex, but a softer low acrylonitrile ("AN") polymer as a nonfoamed latex is preferred. The textured surface of a foamed latex provides sweat absorption by means of the foam structure as well as providing a low surface contact area to the skin. Air circulation is enhanced, giving a reduced clammy feeling to skin compared to that of smooth rubber.

[0034] Additives, such as thickeners, accelerators, curatives or curing agents are used in the various embodiments of the textured surface coatings of the present invention. Useful thickeners include, but are not limited to, ammonium polyacrylate, methylcellulose, and polyvinyl alcohol. Useful accelerators include, but are not limited to, zinc diethylthiocarbamate ("ZDEC"), zinc dibutylthiocarbamate ("ZDBC"), zinc dimethylthiocarbamate ("ZDMC"), zinc butyl ethyl dithiocarbamate ("ZBED"), zinc mercaptothiazole ("ZMBT"), mercaptothiazole ("MBT"), and diphenylguanidine ("DPG"). Other useful curatives and additives include, for example, sulphur and zinc oxide. Foaming and frothing agents are useful in the various embodiments of the textured surface coatings of the present invention. Traditional processing aids to aid gel formation and control webbing may be used. Other useful commercial additives include aqueous ammonia, wetting agents, surfactants, and antiwebbing agents. One useful wetting agent is TRITON X-100, available from Union Carbide Ltd., U.S.A. One useful antiwebbing agent is DEFOAMER 1512M, available from Hercules Ltd., Wilmington, Del.
In the latex art, quantities of components are expressed in terms of parts by weight per hundred parts by weight rubber ("phr"). In the embodiments of the present invention, accelerators can be used in the range of between about 0.5 phr to about 1.5 phr individually, or in combination where the sum of the parts preferably should not exceed that range. A preferred embodiment will now be further described in the following example.

EXAMPLE 1

Step 1. The following coagulant solution is prepared:

Calcium nitrate, aq. concentration 35% by volume

---

TRITON X 100  
DEFOAMER 1512M

About 0.1% by volume  
About 0.5% by volume

---

The coagulant solution is heated to 30 to 40°C. A clean porcelain glove former is evenly coated over its surface by immersion in the coagulant solution. The speed of immersion is approx. 1.5 cm/sec, the dwell time is 5 to 10 sec, and the extraction speed is approx. 0.75 cm/sec.

Step 2. The coagulant coated former is inverted to fingers up position and dried in a warm gentle air flow (30 to 40°C) for 2 to 2.5 minutes.

Step 3. The dried coagulant coated former is inverted to fingers down position and dipped into a nitrile latex compound:

| REVENEX 99G43 | 100 phr |
| Sulphur | 0.5 phr |
| Zinc Oxide | 3.0 phr |
| ZMBT | 0.7 phr |

The pH of this latex has been adjusted to 9.0 (with ammonia or potassium hydroxide), and the viscosity of the latex has been adjusted to 500 cps (Brookfield viscometer model DV1+, spindle #2 @ 30 rpm) using ammonium polyacrylate. The latex is held at 20 to 25°C. The speed of immersion is approx. 1 to 3 cm/sec, the dwell time in the latex is approx. 10 to 30 sec, and the extraction speed is approx. 2 cm/sec.

Step 8. The nitrile glove shell, now having a liquid second layer of nitrile latex overdip is inverted to fingers up position to disperse finger drips and then quickly reinverted back to fingers down position. Particles of sodium chloride (99% purity, mean particle size 400 microns) are applied to the second layer of latex in a fluidized bed apparatus, available from Campbell Cotts Ltd., Southampton, England. The glove shell is held at ambient temperature. The speed of immersion into the fluidized bed is approx. 2 cm/sec, the dwell time in the fluidized bed is 5 to 10 sec, and the extraction speed is approx. 2 cm/sec. In a variant of step 8, during the dwell time the fluidized bed may be turned off so as to achieve a sharper/deeper impression into the latex layer. During the extraction of the former the fluidized bed is turned back on.

Step 9. The salt coated shell is washed with water at ambient temperature to remove sodium chloride remaining at the now gelled surface.

Step 10. The gelled glove product is then leached in warm water at approx. 40°C for approx. 15 minutes.

Step 11. The gelled glove product is dried and vulcanised in a conventional recirculating hot air oven at 130°C for approx. 60 minutes.

Step 12. The cured glove is allowed to cool and is then reversed stripped off the former. In a variant of step 12, an internal lining (e.g. cotton flocking) may be attached.

Step 13. The finished, cured glove is then turned inside out so that the textured surface is on the outside of the glove.

A pinch force test was developed to measure the grip force required to lift a steel weight having a polished surface and covered with a mixture of hydraulic oil and grease. Several gloves were tested, including a glove prepared according to Example 1 ("Textured Glove"), and known nitrile gloves of similar formulation, yet not having a textured surface coating, namely Ansell SOLVEX 37-676 and Ansell SOLKNIT 39-122.

The test apparatus employed a model PPS-6 Kg mass balance available from Applied Instruments Ltd., United Kingdom, modified with a stainless steel strip attached to its underside, directly opposite the flat stainless steel load pan of the balance. The entire apparatus is turned on its side for the test, in such a manner that it can be gripped by a gloved hand against the force of gravity while pointed toward the floor. The stainless steel surfaces were coated with mixture of hydraulic oil and grease for the following testing. The pinch force test was carried out as follows.

1. The test glove is donned by a volunteer tester.
2. The tester grips the apparatus at right angles to the surfaces using the thumb and the first finger (or second finger) only, one digit on each opposing surface at approx. 4 cm along the surface toward the floor, using only the last digit pads on finger and thumb as contact points.
The tester squeezes and attempts to lift the apparatus, then holds the apparatus with enough force to hold it motionless without slip. The immediate grip force is recorded in mass units read off of the mass balance. After the initial gripping and lifting, a steady grip force is recorded after approx. 5 to 10 seconds. The grip is steadily loosened in order to allow the apparatus to slip from the grip. The minimal grip force is recorded at the point of slip. Additional weights are subsequently added to the apparatus and steps 1-7 repeated.

Our test data, shown in Table 1, demonstrates that the textured surface, when used as the surface of a nitrile glove (or any latex glove) as prepared in Example 1, and then used to handle wet or oily objects, provides exceptional user grip and control results.

*Represents the approximate weight of the apparatus. **Cumulative weight.

As shown in Table 1, the textured glove made according to Example 1 exhibits improved grip control and confidence when slip occurs. When compared to conventional nitrile gloves, the textured glove requires the lowest grip force to lift the three weights defined by the apparatus. The textured glove required 29% and 31% less immediate grip force to lift the first weight and second weight, respectively, compared to the SOLVEX 37-676 glove; and required 20% less steady grip force to hold the second weight compared to the SOLVEX 37-676 glove. The textured glove required 24% and 44% less immediate grip force to lift the first weight and second weight, respectively, compared to the SOL knit 39-122 glove; and required 19% and 49% less steady grip force to hold the first weight and second weight, respectively, compared to the SOL knit 39-122 glove. It is notable that sudden, violent slip can occur using conventional gloves. In contrast, the textured glove provides control of slip even when slip occurred.

The use of the terms “a” and “an” and the” and similar referents in the context of describing the invention (especially in the context of the following claims) are to be construed to cover both the singular and the plural, unless otherwise indicated herein or clearly contradicted by context. Recitation of ranges of values herein are merely intended to serve as a shorthand method of referring individually to each separate value falling within the range, unless otherwise indicated herein, and each separate value is incorporated into the specification as if it were individually recited herein. All methods described herein can be performed in any suitable order unless otherwise indicated herein or otherwise clearly contradicted by context. The use of any and all examples, or exemplary language (e.g., “such as”) provided herein, is intended merely to better illuminate the invention and does not pose a limitation on the scope of the invention unless otherwise claimed. No language in the specification should be construed as indicating any non-claimed element as essential to the practice of the invention.

While the invention has been described in conjunction with specific embodiments thereof, it is evident that alternatives, modifications and variations will be apparent to those skilled in the art in light of the foregoing description. It should be understood that the illustrated embodiments are exemplary only, and should not be taken as limiting the scope of the invention. Accordingly, it is intended to embrace all such alternatives, modifications and variations as fall within the spirit and broad scope of the appended claims.

1. A textured polymeric layer having an outer surface comprising:
   a plurality of cavities, each cavity having a perimeter, wherein the perimeter of each cavity is defined by a ridge circumscribing substantially an entire perimeter of each cavity; and
   a plurality of channels located between the ridges, wherein the cavities have interior cavity shapes of diameter in a range of about 50 microns to about 2000 microns.

2. The layer of claim 1, wherein the polymeric layer is made from an unfoamed polymer, and wherein the ridges have substantially the same height measured from the base of the textured polymeric layer.

3. The textured polymeric layer of claim 1, wherein the textured polymeric layer is disposed at least partially on another polymeric layer.

4. The textured polymeric layer of claim 1, wherein the textured polymeric layer is disposed at least partially on fabric.

5. The textured polymeric layer of claim 4, wherein the fabric is a knitted fabric.

6. An article having a textured polymeric surface comprising:
   a polymeric layer coated on at least a portion of the article;
   a plurality of cavities formed in the polymeric layer, wherein each cavity in the plurality of cavities have a size between about 50 microns to about 2000 microns,
and wherein a majority of the plurality of cavities have encircling perimeter ridges; and a plurality of channels formed in the polymeric layer between the encircling perimeter ridges.

7. The article of claim 6, wherein the encircling perimeter ridges have substantially the same height relative to a base of the polymeric layer.

8. The article of claim 6, wherein the polymeric layer comprises a foamed polymer.

9. The article of claim 6, wherein the article is a fabric.

10. The article of claim 9, wherein the fabric is a knitted fabric.

11. A textured surface covering at least a portion of an article, the surface made by a process comprising:
applying a coagulant to a portion of the article;
applying a foamed or an unfoamed polymer to the coagulant-applied portion of the article to form an ungelled layer of the foamed or the unfoamed polymer on the coagulant-applied portion;
applying particles of salt to the ungelled layer, wherein the particles of salt have a size between about 50 microns to about 2000 microns, and wherein the salt particles coagulate at least partially the ungelled layer where the salt particles contact the ungelled layer;
exposing the ungelled layer to a solvent for removing the particles of salt and at least some material from the ungelled layer between the particles of salt; and curing the ungelled layer to form a textured surface comprising cavities that are reverse impressions of the salt particles and channels between the reverse impressions.

12. The textured surface of claim 11, wherein exposing the ungelled layer to the solvent comprises washing the ungelled layer with the solvent, which removes the salt particles and the at least some material from the ungelled layer between the salt particles.

13. The textured surface of claim 11, wherein the textured surface is disposed at least partially on another polymeric layer.

14. The textured surface of claim 11, wherein the article is a fabric.

15. The textured surface of claim 14, wherein the fabric is a knitted fabric.
