Publication Classification(51) **Int. Cl.⁷ G06F 19/00**

A system and methods to allow multiple stations in geographically dispersed locations to monitor and track vehicle repair record and service status information in a coordinated fashion. In a service area comprised of a number of geographically-bounded service regions, at least one regional communications terminal is provided in communication with a plurality of local communications terminals. Each local communications terminal and regional communications terminal communicates with a vehicle service status database. Vehicle service events are entered into a vehicle tracking system and maintained using the vehicle status database. Database files are exchanged between local communications terminals and regional communications terminals and with a central equipment manager in order to provide timely and accurate dissemination of service status. Vehicle service status, including an equipment availability prediction, is shared with marketing offices and retail locations to enable personnel at such locations to make informed decisions in allocating particular equipment to a customer based on the customer's needs.

FIG. 20

VEHICLE SERVICE STATUS TRACKING SYSTEM AND METHOD

[0001] A portion of this disclosure contains material which is subject to copyright protection. The copyright owner has no objection to the facsimile reproduction by anyone of the patent document or patent disclosure, as it appears in the Patent and Trademark Office files or records, but otherwise reserves all copyright rights whatsoever.

FIELD OF THE INVENTION

[0002] The present invention relates to a vehicle service status tracking system and method.

SUMMARY OF THE INVENTION

[0003] The present invention provides a system and methods to allow multiple stations in geographically dispersed locations to monitor and track vehicle repair record and service status information. In a service area comprised of a number of geographically-bounded service regions, at least one regional communications terminal is provided in communication with a plurality of local communications terminals. Each local communications terminal is typically located at a separate repair or service location having responsibility for servicing the vehicles temporally located within the region.

[0004] The present invention provides a system and methods for maintaining and disseminating vehicle service information within and among regions. Vehicle service events are entered into a vehicle tracking system and maintained using a vehicle status database. Database files are exchanged among regional communications terminals and with a central equipment manager in order to provide timely and accurate dissemination of service status.

[0005] A further aspect of the present invention is the sharing of vehicle service status with marketing offices and retail locations. This enables personnel at such locations to understand the repair history of a particular vehicle.

[0006] A still further aspect of the present invention is the ability to predict vehicle availability or time of return from service. The system and methods according to the present invention provide an availability prediction for operations personnel to allocate fleet vehicles while taking account of anticipated vehicle demand.

[0007] Other advantages and objectives of the present invention are apparent upon inspection of this specification and the drawings appended thereto.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] FIG. 1 is a block diagram depicting the overall arrangement of a preferred embodiment of a vehicle tracking system according to the present invention;

[0009] FIG. 2 is a functional block diagram of a preferred embodiment of a vehicle tracking system according to the present invention;

[0010] FIG. 3 depicts the components of a preferred implementation of a local communications terminal and a regional communications terminal according to the present invention;

[0011] FIG. 4 depicts the contents of a vehicle status database according to a preferred embodiment of the present invention;

[0012] FIG. 5 depicts a preferred format for a control number for use with a vehicle tracking system according to the present invention;

[0013] FIG. 6 is an information flow diagram depicting the flow of vehicle repair and service status information throughout a preferred vehicle tracking system;

[0014] FIGS. 7A and 7B depict processing accomplished by a local communications terminal in a preferred embodiment of the present invention;

[0015] FIG. 8 depicts the processing accomplished by a regional communications terminal in a preferred embodiment of the present invention;

[0016] FIG. 9 depicts vehicle repair history processing performed by a local communications terminal and a regional communications terminal according to the present invention;

[0017] FIG. 10 is a preferred user interface by which a user enters equipment/location validation information at a local communications terminal according to the present invention;

[0018] FIG. 11 is a preferred user interface for a local communications terminal according to the present invention by which a user may enter portions of vehicle repair/service event information;

[0019] FIG. 12 is a preferred user interface for a local communications terminal according to the present invention by which a user may modify portions of vehicle repair/service event information;

[0020] FIG. 13 is a preferred user interface by which a local communications terminal according to the present invention displays a control number to a user;

[0021] FIG. 14A is a preferred user interface for a local communications terminal according to the present invention providing the capability for a user to edit location information and view location-related reports;

[0022] FIG. 14B is a preferred user interface for a local communications terminal according to the present invention providing the capability for a user to view a variety of repair shop oriented reports;

[0023] FIG. 14C is a preferred user interface for a local communications terminal according to the present invention providing the capability for a user to view a variety of traffic reports;

[0024] FIG. 14D is a preferred user interface for a local communications terminal according to the present invention providing the capability for a user to view a variety of special programs reports;

[0025] FIG. 15 is a preferred embodiment of an on-screen pop-up multiple breakdown advisory warning provided by a preferred embodiment of the present invention;

[0026] FIG. 16 is an example of a preferred campaign information warning report provided by a central equipment manager according to the present invention;

[0027] FIG. 17 is a preferred advisory warning generated by a local communications terminal and a regional communications terminal according to the present invention;

[0028] FIG. 18 is a preferred report generated by a local communications terminal according to the present invention showing a portion of the out-of-service vehicles whose service has not been completed within a projected repair time;

[0029] FIG. 19 is a preferred display of a calculated repair/service time provided by a local communications terminal according to the present invention; and

[0030] FIG. 20 is a preferred down equipment report generated by a local communications terminal and a regional communications terminal according to the present invention displaying information contained in a vehicle history file.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0031] The present invention provides a system and methods to allow multiple stations in geographically dispersed locations to monitor and track vehicle repair record and service status information regardless of vehicle location.

[0032] FIG. 1 illustrates the overall arrangement of a preferred embodiment of a vehicle tracking system 100 according to the present invention. Referring now to FIG. 1, vehicle tracking system 100 includes a central equipment manager 101, regional communications terminals 102, and local communications terminals 103. Preferably, a single regional communications terminal 102 is allocated to support a given particularly-bounded geographical region. For example, FIG. 1 shows three regions (Regions A, B, and C) each having a regional communications terminal 102. However, one or more additional regional communications terminals 102 may provide backup communications and processing for one or more regions.

[0033] Each regional communications terminal 102 is preferably located in a regional company office or other such location having responsibility for maintaining and servicing the vehicles within a particular geographical region or regions. Each local communications terminal 103 is preferably located in a repair and service station having responsibility for repairing broken-down or out-of-service vehicles, as well as for providing routine service and preventive maintenance, for vehicles temporally within that region. A local communications terminal 103 communicates with a regional communications terminal 102 within its local region; however, a given local communications terminal 103 may communicate with one or more regional communications terminals 102 within or outside of its local region. Regional communications terminal 102 is thus provided in shared communication with multiple local communications terminals 103.

[0034] FIG. 2 further illustrates the logical relationships among these elements of vehicle tracking system 100. Referring now to FIG. 2, each regional communications terminal 102 communicates with central equipment manager 101. Central equipment manager 101 maintains at a single office location vehicle service status information for all regions, and periodically disseminates this information to all regional communications terminals 102 and local communications terminals 103.

[0035] In a preferred embodiment, each regional communications terminal 102 communicates with central equipment manager 101 and multiple local communications terminals 103 using a frame relay network 104. Frame relay is a packet-switched protocol used for connecting terminals to a Wide Area Network (WAN) supporting T-1 or T-3 data rates. Alternatively, frame relay network 104 comprises public switched or private telecommunications circuits such as telephone landlines, the Internet, or wireless transmission systems including, but not limited to, personal communications services, cellular data, satellite, or point-to-point microwave communications. Regional communications terminals 102 are interconnected via frame relay network 104.

[0036] Referring again to FIG. 2, vehicle tracking system 100 includes a vehicle status database 200 operably coupled to each local communications terminal 103 and regional communications terminal 102. A vehicle status database 200 is also operably coupled to central equipment manager 101. In a preferred embodiment, central equipment manager 101 is a mainframe computer system, such as a DEC® VAX™ or IBM® Model 3070 system, having a frame relay gateway and an Internet interface. Alternatively, central equipment manager 101 is implemented according to a client-server architecture. Central equipment manager 101 preferably communicates with regional communications terminals 102 via frame relay network 104 and with local communications terminal 103 via Internet interface 108.

[0037] Central equipment manager 101 transmits a multiple breakdown advisory 215 (see FIG. 6) to all local communications terminals 103 and all regional communications terminals 102, preferably once per 24-hour period. Central equipment manager 101 transmits a multiple breakdown advisory 215 to local communications terminals 103 as a database file via File Transfer Protocol (FTP) using Internet interface 108. Preferably, central equipment manager 101 transmits multiple breakdown advisory 215 to regional communications terminals 102 as a database file via frame relay network 108. Users at repair/service locations having local communications terminal 103 are able to withhold rental of vehicles listed on multiple breakdown advisory 215 if, in the user's judgment, the vehicle's repair history indicates a high likelihood of break-down during an extended trip such as, for example, an inter-regional or cross-country trip. This allows an operator of vehicle tracking system 100 to achieve higher overall customer satisfaction and to save money on operating costs such as vehicle towing.

[0038] Preferably, multiple breakdown advisory 215 is also used to indicate additional conditions affecting the status of a given vehicle such as, but not limited to, a stolen or missing vehicle. For example, FIG. 17 illustrates a preferred advisory warning generated by local communications terminal 103 and regional communications terminal 102 in response to receiving a multiple breakdown advisory 215 from central equipment manager 101 providing and indication of a stolen or missing vehicle.

[0039] Referring again to FIG. 2, a local communications terminal 103 typically provides vehicle service status file 205 to a single regional communications terminal 102. However, as shown in FIG. 2, local communications terminal 103 may alternatively provide vehicle service status file 205 to multiple regional communications terminals 102

located in different regions. The latter situation may occur, for example, when local communications terminal **103** is located sufficiently physically proximate to two or more regional communications terminals **102** such that it is advantageous for that repair/service location to support vehicles within the control span of either or both regional offices.

[0040] Referring again to **FIG. 2**, local communications terminal **103** includes an interface for receiving an entity master list **280** (see **FIG. 6**) transmitted from central equipment manager **101**. Preferably, central equipment manager **101** transmits entity master list **280** using FTP via Internet interface **108**. The entity master list **280** is useful for identifying the current set of regional company offices, retail locations, and marketing offices.

[0041] Local communications terminal **103** includes an interface to an Automated Repair Management System (ARMS) **105** for receiving vehicle history file **210** transmitted from central equipment manager **101**. In a preferred embodiment, ARMS **105** is a frame relay network. Central equipment manager **101** preferably transmits vehicle history file **210** to local communications terminals **103** as a database file via File Transfer Protocol (FTP) using ARMS **105**.

[0042] Referring again to **FIG. 2**, local communications terminal **103** preferably includes interfaces to retail outlet **106** and marketing office **107** using frame relay network **104**. Local communications terminal **103** transmits vehicle service status file **205** to retail outlet **106** and marketing office **107** via frame relay network **104**. In a preferred embodiment, retail outlet **106** and marketing office **107** include an availability database **300** containing, without limitation, information concerning the availability status of vehicles in the fleet. Users at retail outlet **106** and marketing office **107** are able to allocate vehicle resources to customers, and to predict equipment availability to customers, using the vehicle repair and service status provided in vehicle service status file **205** and availability database **300**.

[0043] **FIG. 3** shows a preferred implementation of local communications terminal **103** and regional communications terminal **102**. Local communications terminal **103** and regional communications terminal **102** include a personal computer based server **150** having standard peripherals including monitor, printer (not shown), keyboard and mouse (not shown), and having an interface to a frame relay network **104** and an Internet interface **108**, and having a vehicle status database **200**. In a preferred embodiment, server **150** is an Intel® Pentium™-based personal computer (PC) running Microsoft® Windows™ operating system software, including Windows™ version 4.0. Server **150** executes programmed instructions in accordance with a software application program in order to achieve the functionality described herein. In a preferred embodiment, server **150** application software is written in FoxPro™ version 2.6 for Microsoft® Windows™. In a preferred embodiment, vehicle tracking system **100** includes two independent application programs: one application program for execution at local communication terminal **103**, and a second application program for execution at regional communications terminal **102**.

[0044] Local communications terminal **103** and regional communications terminal **102** include a web browser and electronic mail capability to enable electronic communication using the Internet, including Hypertext Transport Pro-

tolocol (HTTP), File Transfer Protocol (FTP), and Simple Mail Transfer Protocol (SMTP). In a preferred embodiment, local communications terminal **103** and regional communications terminal **102** use Microsoft® Internet Explorer™ and Outlook™ application software.

[0045] In a preferred embodiment, vehicle status database **200** is implemented using FoxPro™ version 2.6™ version 7.0. Server **150** interfaces with vehicle status database **200** using FoxPro™ queries and instructions.

[0046] **FIG. 4** describes the contents of vehicle status database **200**. Referring now to **FIG. 4**, vehicle status database **200** includes one or more vehicle service status files **205**, a vehicle history file **210**, and multiple breakdown advisory **215**.

[0047] **FIG. 6** illustrates the flow of vehicle repair and service status information comprising vehicle status database **200** throughout vehicle tracking system **100**, as described herein.

[0048] Vehicle service status file **205** is comprised of one or more service event notifications **220**. A service event notification **220** is created or modified by a user, usually a service professional, at a local repair or service location by logging vehicle repair and service information using local communications terminal **103**. Referring again to **FIG. 4**, service event notification **220** may include, for example, a control number **225**, a vehicle identifier **230**, an equipment type indicator **235**, current status **240**, location identifier **245**, date-in-building indicator **250**, type-of-service-required indicator **255**, an availability prediction **260**, and remarks **265**.

[0049] In a preferred embodiment, local communications terminal **103** provides for generation of availability prediction **260** by calculating an average repair/service time for the particular location and providing this information to the user. To calculate the average repair/service time, local communications terminal **103** retrieves from vehicle status database **200** service event notifications **220** for repair/service activities accomplished at this service location during the past thirty days. Local communications terminal **103** then computes an average repair/service time by averaging the number of days from date-in-building **250** to closing of the service event notification **220** for each service event notification within the thirty day period. **FIG. 19** illustrates a preferred display of the calculated repair/service time provided by local communications terminal **103**. Alternatively, a period of time of shorter or longer duration than thirty days is used in calculating the average repair/service time. Preferably, the average repair/service time is calculated daily. Local communications terminal **103** displays the calculated average repair/service time to the user. Local communications terminal **103** further includes an operator interface that allows the user to enter availability prediction **260** using a keyboard, the user having considered a variety of factors including the average repair/service time.

[0050] In a first alternative, local communications terminal **103** calculates availability prediction **260** based on, without limitation, the mean-time-to-repair (typically measured in hours) to complete a particular service job for a particular item of equipment. In this alternative embodiment, vehicle status database **200** further includes a set of mean-time-to-repair values indexed by equipment type **235**

and type-of-service-required **255**. Mean-time-to-repair values are periodically updated in response to changes in the calculated average repair/service time described above. Local communications terminal **103** sets availability prediction **260** equal to the mean-time-to-repair value associated with the particular equipment type **235** and type-of-service-required **255**. Local communications terminal **103** may modify availability prediction **260** based upon user-provided factors such as, but not limited to, the service backlog at this location, staffing levels at this location, and parts availability.

[0051] In a second alternative embodiment, local communications terminal **103** automatically calculates availability prediction **260** by setting availability prediction **260** equal to the date occurring three business days following the date service event notification **220** is entered into vehicle service database **200**. Local communications terminal **103** further includes an operator interface that allows a user to modify availability prediction **260** by manually entering a different projected availability date using a keyboard.

[0052] Local communications terminal **103** stores availability prediction **260** with its associated service event notification **220** record using vehicle status database **200**. In a preferred embodiment, availability prediction **260** is included in the service event notification **220** record as shown in **FIG. 4**. Alternatively, the service event notification **220** record includes a pointer to a memory location containing availability prediction **260**.

[0053] **FIG. 5** shows a preferred control number **225** for use with vehicle tracking system **100**. Referring now to **FIG. 5**, control number **225** is formed by sequentially concatenating two numeric digits corresponding to the current month, two numeric digits corresponding to the current day of the month, and a three-digit sequential service number **275**. Service number **275** is preferably determined by local communications terminal **103** at the time the user enters a new service event notification **220**. A distinct control number **225** is provided for each service request for an individual vehicle. Control number **225** thus patently conveys to an observer an indication of: (1) the date that a particular service event notification **220** was created for the associated vehicle, and (2) the order in which that service event notification **220** was created with respect to other service event notifications **220** logged by that local communications terminal **103** on a particular date.

[0054] Referring again to **FIG. 4**, vehicle service status file **205** is comprised of the service event notifications **220** entered or modified at a local communications terminal **103** since the last time vehicle service status file **205** was uploaded to regional communications terminal **102**. In a preferred embodiment, vehicle service status file **205** is created by local communications terminal **103** immediately prior to uploading it to regional communications terminal **102**. Local communications terminal **103** creates vehicle service status file **205** by formulating a query requesting retrieval all of the service event notifications **220** entered or modified (e.g., service ticket closed at the completion of repair, service location changed) since the time of the most recent upload. The retrieved service event notification **220** records are then stored as vehicle service status file **205** using vehicle status database **200**.

[0055] Referring again to **FIG. 6**, vehicle service status file **205** is then uploaded to regional communications ter-

terminal **102** using frame relay network **104**. In a preferred embodiment, local communications terminal **103** automatically uploads vehicle status file **205** periodically at a frequency of once every 30 minutes. Alternatively, the frequency of upload can be decreased to minimize the number of transmissions or increased to approach real-time notification. Personnel at regional company offices use regional communications terminal **102** to determine equipment status and location in order to manage reservations. For example, if equipment is scheduled to be serviced in a particular region, personnel at other regions will not reserve that vehicle for an inter-regional trip.

[0056] Regional communications terminal **102** aggregates each of the vehicle status files **205** received from local communications terminals **103** into a vehicle service status report **285**. Regional communications terminal **102** then transmits vehicle service status report **285** to central equipment manager **101**. In a preferred embodiment, regional communications terminal **102** automatically uploads vehicle service status report **285** periodically at a frequency of once every 30 minutes. In a preferred embodiment, vehicle service status report **285** is uploaded from regional communications terminal **102** using frame relay network **104**.

[0057] Vehicle history file **210** comprises all of the service event notifications **220** associated with a particular vehicle identifier **230**, preferably including all service event notifications **220** occurring in the previous twelve-month period. Vehicle history file **210** is received by local communications terminal **103** and regional communications terminal **102** from central equipment manager **101** and stored using vehicle status database **200**. **FIG. 20** illustrates a preferred down equipment report generated by local communications terminal **103** and regional communications terminal **102** displaying information contained in vehicle history file **210** received from central equipment manager **101**.

[0058] Vehicle history file **210** preferably includes multiple breakdown advisory **215**, a separate indication also provided by central equipment manager **101**. In a preferred embodiment, multiple breakdown advisory **215** is provided as a separate record of vehicle history file **210**. Users of vehicle tracking system **100** are able to detect root cause problems or other systemic problems based on the pattern of recurring repair/service actions for a particular vehicle provided by vehicle history file **210**. For example, a series of dead battery service events can be indicative of an underlying electrical problem. Local communications terminal **103** and regional communications terminal **102** provide a history search capability to allow a user to review service event notifications **220** for a particular vehicle occurring over a period of time which is preferably the previous twelve-month period.

[0059] **FIGS. 7A and 7B** describe the processing accomplished by local communications terminal **103** in a preferred method of managing a fleet of vehicles, and vehicle repair record and service status information, in vehicle tracking system **100** (see **FIG. 1**) having multiple geographically remote service locations, according to the present invention.

[0060] Referring now to **FIG. 7A**, a user of vehicle tracking system **100** uses local communications terminal **103** to enter and log vehicle repair and service information (block **301**). **FIG. 10** illustrates a preferred user interface for local communications terminal **103** by which a user enters

equipment/location validation information. Specifically, upon a determination of a repair or service action being required for a particular vehicle, a user enters information specific to the repair/service event using local communications terminal 103. Referring again to FIG. 4, such user-entered repair/service event information includes, but is not limited to, vehicle identifier 230, equipment type 235, current status 240, type of service required 255, location 245, date in building 250, and any specific explanatory remarks 265. FIG. 11 depicts a preferred user interface for local communications terminal 103 by which a user may enter portions of vehicle repair/service event information. FIG. 12 depicts a preferred user interface for local communications terminal 103 by which a user may modify portions of vehicle repair/service event information.

[0061] In a typical application, local communications terminal 103 is located in a repair and service station having responsibility for repairing and servicing vehicles. Referring again to FIG. 7A, a user, such as a service professional, preferably enters the repair/service event information using an interactive data entry screen and keyboard/mouse provided by local communications terminal 103. For example, repair/service event information may be manually entered from a written work order, or, alternatively, in conjunction with creation of a written work order.

[0062] Alternatively, local communications terminal 103 receives repair/service event information from an external source via Internet interface 108 (block 303). External sources include, but are not limited to, a mobile repair unit, a remote repair or service location, or other location not equipped with local communications terminal 103. In this case, an external source transmits vehicle repair/service information to local communications terminal 103 using an electronic message such as, for example, an email message, over Internet interface 108.

[0063] After entry or receipt of vehicle repair/service information, local communications terminal 103 generates control number 225 for a new service event notification 220 as described herein in reference to FIG. 5 (block 305). FIG. 13 illustrates a preferred user interface by which local communications terminal 103 displays the generated control number 225 to a user. Local communications terminal 103 also generates availability prediction 260 as described elsewhere herein (block 307). In a preferred embodiment, control number 225 is generated per block 305 prior to availability prediction 260 being generated per block 307; however, these two operations may be accomplished without regard to any particular sequence, or in parallel as well. After obtaining vehicle repair/service information in blocks 301 or 303, generating control number 225 in block 305, and generating availability prediction 260 in block 307, local communications terminal 103 creates service event notification 220 using this information as shown in FIG. 4 (block 309).

[0064] After creating service event notification 220, each such new service event notification 220 is stored in the local vehicle status database 200 operably coupled to the local communications terminal 103 that generated that service event notification 220 (block 311). FIGS. 14A through 14D illustrate a preferred user interface for local communications terminal 103 by which a user may request to receive a variety of service event reports generated by local commu-

nications terminal 103 using the vehicle repair/service information contained in vehicle repair database 200.

[0065] Referring now to FIG. 14A, local communications terminal 103 provides the capability for a user to edit location information and view location-related reports.

[0066] Referring now to FIG. 14B, local communications terminal 103 provides the capability for a user to view a variety of repair shop oriented reports, including reports indicating various aspects of equipment disposition and availability at this location, including equipment for which the scheduled repair date has been exceeded. FIG. 18 illustrates a preferred report generated by local communications terminal 103 showing a portion of the out-of-service vehicles whose service has not been completed within a projected repair time.

[0067] Referring now to FIG. 14C, local communications terminal 103 provides the capability for a user to view a variety of traffic reports.

[0068] Referring now to FIG. 14D, local communications terminal 103 provides the capability for a user to view a variety of special programs reports, including campaign information (received from, for example, a particular vehicle manufacturer), equipment history search, control number search, and shop transfers.

[0069] Referring now to FIG. 7B, service event notification 220 processing as described with respect to FIG. 7A continues as required at local communications terminals 103 (reference blocks 313, 315, and 317). However, new service event notifications 220 are periodically uploaded to regional communications terminal 102 (block 331), marketing offices 107 (block 333), and retail outlets 106 (block 335). Local communications terminal 103 maintains a series of software-implemented upload timers used to determine when the current set of new service event notifications 220 are collected and uploaded to each of these destination nodes. In a preferred embodiment, a first timer, TIMER_1, is used to determine when local communications terminal 103 uploads the current set of new service event notifications 220 to regional communications terminal 102 (block 313). Another timer, TIMER_2, is used to determine when local communications terminal 103 uploads the current set of new service event notifications 220 to marketing office 107 (block 315). A third timer, TIMER_3, is used to determine when local communications terminal 103 uploads the current set of new service event notifications 220 to retail outlets 106 (block 317).

[0070] In a preferred embodiment, local communications terminal 103 employs three separate upload timers each having independent expiration times but each being set to a value of approximately 30 minutes. The timer values are each independently modifiable by the user. In a first alternative embodiment, a single timer may be used to effect periodic uploading of the current set of new service event notifications 220 to regional communications terminal 102, marketing offices 107, and retail outlets 106. In a second alternative embodiment, service event notification 220 upload is accomplished aperiodically in response to the occurrence of one or a combination of external events, or upon receiving an upload request from the destination node.

[0071] Referring again to FIG. 7B, upon the expiration of upload TIMER_1 (block 313), local communications termi-

nal 103 retrieves from its local vehicle status database 200 the set of service event notifications 220 entered since the time of the last upload action associated with TIMER_1 (block 319). In a preferred embodiment, this is accomplished by formulating a database query to retrieve service event notifications 220 having entry dates later in time than the most recently accomplished upload action associated with TIMER_1. This database query is then transmitted to vehicle status database 200. Vehicle status database 200 responds by providing to local communications terminal 103 the set of service event notifications 220, if any, meeting the query criteria.

[0072] Local communications terminal 103 gathers the set of service event notifications 220 from block 319 into a vehicle service status file 205 (block 325) as described in FIG. 4. In block 331, local communications terminal 103 then uploads vehicle service status file 205 to regional communications terminal 102 via Frame relay network 104. Similarly, upon the expiration of upload TIMER_2 (block 315), local communications terminal 103 retrieves from its local vehicle status database 200 the set of service event notifications 220 entered since the time of the last upload action associated with TIMER_2 (block 321). Local communications terminal 103 gathers the set of service event notifications 220 from block 321 into a vehicle service status file 205 (block 327). In block 333, local communications terminal 103 then uploads vehicle service status file 205 to marketing office 107 via frame relay network 104.

[0073] Further, upon the expiration of upload TIMER_3 (block 317), local communications terminal 103 retrieves from its local vehicle status database 200 the set of service event notifications 220 entered since the time of the last upload action associated with TIMER_3 (block 323). Local communications terminal 103 gathers the set of service event notifications 220 from block 323 into a vehicle service status file 205 (block 329). In block 335, local communications terminal 103 then uploads vehicle service status file 205 to retail outlet 106 via frame relay network 104.

[0074] Referring now to FIG. 8, regional communications terminal 102 receives vehicle service status file 205 from one or more local communications terminals 103 via frame relay network 104 (block 351). Upon receiving vehicle service status file 205, regional communications terminal 102 stores vehicle service status file 205 using its local vehicle status database 200 (block 353).

[0075] Regional communications terminal 102 maintains a software-implemented upload timer to determine when the current set of new vehicle service status files 205 are to be collected and uploaded to central equipment manager 101 (block 355). In a preferred embodiment, regional communications terminal 102 upload timer is set to a value of approximately 30 minutes. The timer value may be modified as required by the user. Alternatively, vehicle service status file upload is accomplished aperiodically in response to the occurrence of one or a combination of external events, or upon receiving a request for upload from central equipment manager 101.

[0076] Upon the expiration of the upload timer (block 355), regional communications terminal 102 retrieves from its local vehicle status database 200 the set of vehicle service status files 205 entered since the time of the last upload action (block 357). In a preferred embodiment, this is

accomplished by formulating a database query to retrieve vehicle service status files 205 having receipt dates later in time than the most recently accomplished upload action. This database query is then transmitted to vehicle status database 200. Vehicle status database 200 responds by providing to regional communications terminal 102 the set of vehicle service status files 205, if any, meeting the query criteria.

[0077] Regional communications terminal 102 collects the set of vehicle service status files 205 from block 357 into a vehicle service status report 285 (block 359). In a preferred embodiment, vehicle service status report 285 is a single file formed by sequentially appending the contents (i.e., service event notification 220 records) of each vehicle service status file 205 in a sequence from oldest to newest (with respect to time of receipt). In block 361, regional communications terminal 102 then uploads vehicle service status report 285 to central equipment manager 101 via frame relay network 104.

[0078] In a preferred embodiment, local communications terminal 103 and regional communications terminal 102 receive vehicle history file 210, entity master 280, and multiple breakdown advisory 215 from central equipment manager 101 once per 24-hour period.

[0079] Referring now to FIG. 9, central equipment manager 101 periodically transmits vehicle history file 210 to local communications terminals 103 and regional communications terminals 102 using electronic network 105. Electronic network 105 may be referred to as an Automated Repair Management System (ARMS). Local communications terminal 103 and regional communications terminal 102 receive vehicle history file 210 (block 371) and store the received vehicle history file 210 using vehicle status database 200 (block 377).

[0080] Local communications terminal 103 and regional communications terminal 102 receive additional information from central equipment manager 101 via electronic network 105. For example, FIG. 16 provides an example campaign information warning report received from central equipment manager 101.

[0081] Referring again to FIG. 9, central equipment manager 101 periodically transmits entity master 280 list to local communications terminals 103 using Internet interface 108 and to regional communications terminals 102 using frame relay network 104. Upon receiving entity master 280 list (block 373), local communications terminal 103 and regional communications terminal 102 store the received entity master 280 list using vehicle status database 200 (block 379).

[0082] Central equipment manager 101 also transmits multiple breakdown advisory 215 to all local communications terminals 102 and all regional communications terminals 103. Upon receiving a multiple breakdown advisory (block 375), local communications terminal 103 and regional communications terminal 102 provide a multiple breakdown advisory warning (block 387) to alert the user to consider this information in assessing the suitability of the vehicle for a particular rental itinerary. In a preferred embodiment, local communications terminal 103 and regional communications terminal 102 provide the advisory warning in the form of an on-screen pop-up warning box on

the display device of processor **150**. **FIG. 15** illustrates a preferred embodiment of an on-screen pop-up multiple breakdown advisory warning.

[0083] In addition, regional communications terminal **102** reviews service event notifications **220** received from local communications terminals **103** in vehicle service status files **205** for actual service completion times (block **381**).

[0084] In a preferred embodiment, regional communications terminal **102** determines if the repair/service action has not occurred by the time specified by availability prediction **260**. Specifically, if the repair/service action is not accomplished within 24 hours of the projected completion date specified by availability prediction **260** (block **383**), then regional communications terminal **102** provides a service time advisory warning (block **389**). The time in excess of the availability prediction **260** that triggers the advisory warning is user-programmable from as little as two hours to as long as four weeks. In a preferred embodiment, regional communications terminal **102** provides the service time advisory warning in the form of an on-screen pop-up warning text box on the display device of processor **150**. The user may thereafter take corrective action such as, for example, telephoning the service location to determine the cause of the service delay.

[0085] In a preferred embodiment, local communications terminal **103** reviews service event notifications **220** for vehicles whose number of repair/service actions exceed a pre-defined threshold (block **385**). If the repair threshold has been exceeded, then regional communications terminal provides multiple breakdown advisory **215** as described above for block **387**. In a preferred embodiment, the pre-defined threshold for multiple breakdown advisory is two service event notifications **220** within the last sixty-day period. If the threshold is exceeded, multiple breakdown advisory **215** provides the user the option of retrieving and displaying or printing the service event notifications **220** associated with the vehicle.

[0086] Thus, a system and methods for managing a fleet of vehicles has been shown that allows multiple geographically dispersed locations to monitor and track vehicle service status, including generating a prediction of vehicle availability.

[0087] While the above description contains many specific details of the preferred embodiments of the present invention, these should not be construed as limitations on the scope of the invention, but rather are presented in the way of exemplification. Other variations are possible. Accordingly, the scope of the present invention should be determined not by the embodiments illustrated above, but by the appended claims and their legal equivalents.

10. A method comprising the steps of:

maintaining, in a moving equipment database, status information of a plurality of moving equipment items;

receiving an event notification related to one of the moving equipment items in the plurality of moving equipment items; and, predicting a status change time based on the event notification.

11. The method of claim 10, further comprising the step of modifying status information related to the one of the moving equipment items in the plurality of moving equipment items based on the event notification.

12. The method of claim 10, wherein status information includes availability information.

13. The method of claim 10, wherein the event notification is a service event notification.

14. The method of claim 13, further comprising the step of modifying a service history of the one of the moving equipment items in the plurality of moving equipment items based on the service event notification.

15. The method of claim 13, further comprising the step of determining when a predetermined number of service event notifications has been received within a predetermined time period.

16. The method of claim 15, further comprising the step of generating a notification when it is determined that the predetermined number of service event notifications has been received within the predetermined time period.

17. The method of claim 15, wherein the predetermined number of service event notifications is two service event notifications.

18. The method of claim 15, wherein the predetermined time period is a sixty day period.

19. The method of claim 10, further comprising the steps of:

changing a status of the one of the moving equipment items in the plurality of moving equipment items to a first indicator based on the event notification;

tracking a time period while the status remains at the first indicator; and,

generating a notification if the time period exceeds a predetermined amount.

20. The method of claim 19, wherein the predetermined amount is twenty-four hours.

21. The method of claim 19, wherein the predetermined amount is an overdue amount of time past the status change time.

22. The method of claim 21, wherein the overdue amount of time is selectable from two hours to four weeks.

23. An article of manufacture comprising a program storage medium having computer readable program code embodied therein comprising:

computer readable code for maintaining, in a moving equipment database, status information of a plurality of moving equipment items;

computer readable code for receiving an event notification related to one of the moving equipment items in the plurality of moving equipment items; and,

computer readable code for predicting a status change time based on the event notification.

24. The article of manufacture of claim 23, further comprising computer readable code for modifying status infor-

mation related to the one of the moving equipment items in the plurality of moving equipment items based on the event notification.

25. The article of manufacture of claim 23, wherein status information includes availability information.

26. The article of manufacture of claim 23, wherein the event notification is a service event notification.

27. The article of manufacture of claim 26, further comprising computer readable code for modifying a service history of the one of the moving equipment items in the plurality of moving equipment items based on the service event notification.

28. The article of manufacture of claim 26, further comprising computer readable code for determining when a predetermined number of service event notifications has been received within a predetermined time period.

29. The article of manufacture of claim 28, further comprising computer readable code for generating a notification when it is determined that the predetermined number of service event notifications has been received within the predetermined time period.

30. The article of manufacture of claim 28, wherein the predetermined number of service event notifications is two service event notifications.

31. The article of manufacture of claim 28, wherein the predetermined time period is a sixty day period.

32. The article of manufacture of claim 23, further comprising:

computer readable code for changing a status of the one of the moving equipment items in the plurality of moving equipment items to a first indicator based on the event notification;

computer readable code for tracking a time period while the status remains at the first indicator; and,

computer readable code for generating a notification if the time period exceeds a predetermined amount.

33. The article of manufacture of claim 32, wherein the predetermined amount is twenty-four hours.

34. The article of manufacture of claim 32, wherein the predetermined amount is an overdue amount of time past the status change time.

35. The article of manufacture of claim 34, wherein the overdue amount of time is selectable from two hours to four weeks.
