## Sulphonamide Derivatives

The present invention relates to the potentiation of glutamate receptor function using certain sulphonamide derivatives. It also relates to novel sulphonamide derivatives, to processes for their preparation and to pharmaceutical compositions containing them.

In the mammalian central nervous system (CNS), the transmission of nerve impulses is controlled by the interaction between a neurotransmitter, that is released by a sending neuron, and a surface receptor on a receiving neuron, which causes excitation of this receiving neuron. L-Glutamate, which is the most abundant neurotransmitter in the CNS, mediates the major excitatory pathway in mammals, and is referred to as an excitatory amino acid (EAA). The receptors that respond to glutamate are called excitatory amino acid receptors (EAA receptors). See Watkins \& Evans, Ann. Rev. Pharmacol. Toxicol., 21, 165 (1981); Monaghan, Bridges, and Cotman, Ann. Rev. Pharmacol. Toxicol., 29, 365 (1989); Watkins, Krogsgaard-Larsen, and Honore, Trans. Pharm. Sci., 11, 25 (1990). The excitatory amino acids are of great physiological importance, playing a role in a variety of physiological processes, such as long-term potentiation (learning and memory), the development of synaptic plasticity, motor control, respiration, cardiovascular regulation, and sensory perception.

Excitatory amino acid receptors are classified into two general types. Receptors that are directly coupled to the opening of cation channels in the cell membrane of the neurons are termed "ionotropic". This type of receptor has been subdivided into at least three subtypes, which are defined by the depolarizing actions of the selective agonists $N$-methyl-D-aspartate (NMDA), alpha-amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA), and kainic acid (KA). The second general type of receptor is the G-protein or second messenger-linked "metabotropic" excitatory amino acid receptor. This second type is coupled to multiple
second messenger systems that lead to enhanced phosphoinositide hydrolysis, activation of phospholipase D, increases or decreases in c-AMP formation, and changes in ion channel function. Schoepp and Conn, Trends in Pharmacol. Sci., 14, 13 (1993). Both types of receptors appear not only to mediate normal synaptic transmission along excitatory pathways, but also participate in the modification of synaptic connections during development and throughout life. Schoepp, Bockaert, and Sladeczek, Trends in Pharmacol. Sci., 11, 508 (1990); McDonald and Johnson, Brain Research Reviews, 15, 41 (1990).

AMPA receptors are assembled from four protein subunits known as GluR1 to GluR4, while kainic acid receptors are assembled from the sub-units GluR5 to GluR7, and KA-1 and KA-2. Wong and Mayer, Molecuiar Pharmacology 44: 505510, 1993. It is not yet known how these sub-units are combined in the natural state. However, the structures of certain human variants of each sub-unit have been elucidated, and cell lines expressing individual sub-unit variants have been cloned and incorporated into test systems designed to identify compounds which bind to or interact with them, and hence which may modulate their function. Thus, European patent application, publication number EP-A20574257 discloses the human sub-unit variants GluR1B, GluR2B, GluR3A and GluR3B. European patent application, publication number EP-A1-0583917 discloses the human subunit variant GluR4B.

One distinctive property of AMPA and kainic acid receptors is their rapid deactivation and desensitization to glutamate. Yamada and Tang, The Journal of Neuroscience, September 1993, 13(9): 3904-3915 and Kathryn M. Partin, J. Neuroscience, November 1, 1996, 16(21): 6634-6647. The physiological implications of rapid desensitization, and deactivation if any, are unknown.

It is known that the rapid desensitization and deactivation of AMPA and/or kainic acid receptors to glutamate may be inhibited using certain compounds. This
action of these compounds is often referred to in the alternative as "potentiation" of the receptors. One such compound, which selectively potentiates AMPA receptor function, is cyclothiazide. Partin et al., Neuron. Vol. 11, 1069-1082, 1993. Compounds which potentiate AMPA receptors, like cyclothiazide, are often referred to as ampakines.

Ampakines have been shown to improve memory in a variety of animal tests. Staubli et al., Proc. Natl. Acad. Sci., Vol. 91, pp 777-781, 1994, Neurobiology, and Arai et al., The Journal of Pharmacology and Experimental Therapeutics, 278: 627-638, 1996.

It has now been found that cyclothiazide and certain sulphonamide derivatives potentiate agonist-induced excitability of human GluR4B receptor expressed in HEK 293 cells. Since cyclothiazide is known to potentiate glutamate receptor function in vivo, it is believed that this finding portends that the sulphonamide derivatives will also potentiate glutamate receptor function in vivo, and hence that the compounds will exhibit ampakine-like behavior.

Accordingly, the present invention provides a method of potentiating glutamate receptor function in a mammal requiring such treatment, which comprises administering an effective amount of a compound of formula

The compounds of formula I may be prepared by reacting a compound of formula

$$
\mathrm{R}^{1}-\mathrm{L}-\mathrm{NH}_{2} \quad \mathrm{II}
$$

with a compound of formula

$$
\mathrm{R}^{2} \mathrm{SO}_{2} \mathrm{X} \quad \mathrm{III}
$$

in which $X$ represents a leaving atom or group, followed where necessary and/or desired by forming a pharmaceutically acceptable salt.

The leaving atom or group represented by X may be, for example, a halogen atom such as a chlorine or bromine atom.

The reaction is conveniently performed in the presence of a base, for example an alkali metal hydroxide such as sodium hydroxide, an alkali metal carbonate such as potassium carbonate, a tertiary amine such as triethylamine or 1,8-diazabicyclo[5.4.0]undec-7-ene.

Suitable solvents include halogenated hydrocarbons such as dichloromethane.

The reaction is conveniently performed at a temperature in the range of from -20 to $100^{\circ} \mathrm{C}$, preferably from -5 to $50^{\circ} \mathrm{C}$.

The compounds of formula in which $R^{1}$ represents a 4bromophenyl group may conveniently be converted into other compounds of formula $I$ in which $R$ represents another 4substituted phenyl group by reaction with an appropriate boronic acid derivative, for example, a benzeneboronic acid derivative. The reaction is conveniently performed in the presence of a tetrakis (triarylphosphine)palladium(0) catalyst, such as tetrakis (triphenylphosphine)palladium(0) and a base such as potassium carbonate. Convenient solvents for the reaction include aromatic hydrocarbons, such as toluene. The temperature at which the reaction is conducted is conveniently in the range of from 0 to $150^{\circ} \mathrm{C}$, preferably

75 to $120^{\circ} \mathrm{C}$. Bis aromatic intermediates useful in the preparation of compounds of formula I may be prepared by reacting a bromoaromatic or bromoheteroaromatic compound with an aromatic or heteroaromatic boronic acid in an analogous manner.

The boronic acid derivative used as a starting material may be prepared by reacting a trialkyl borate, such as triisopropyl borate with an appropriate organolithium compound at reduced temperature. For example, 2-fluorobenzeneboronic acid may be prepared by reacting 2 fluorobromobenzene with butyllithium in tetrahydrofuran at about $-78^{\circ} \mathrm{C}$ to afford 2 -fluorophenyl lithium, and then reacting this organolithium compound with triisopropyl borate.

Alternatively, the compounds of formula $I$ in which $R^{1}$ represents a 4-bromophenyl group may be converted to a 4(trimethylstannyl) phenyl or 4-(tri-n-butylstannyl)phenyl group by treatment of the corresponding bromide with a palladium(O) catalyst, such as tetrakis(triphenylphosphine)palladium(0) and hexaalkyldistannane, where the alkyl group is methyl or n-butyl, in an aprotic solvent such as toluene in the presence of a tertiary amine base such as triethylamine, at temperatures ranging from 80 to $140^{\circ} \mathrm{C}$, preferably from 90 to $110^{\circ} \mathrm{C}$.

The compounds of formula $I$ in which $R^{1}$ represents a 4-(tri-n-butylstannyl)phenyl group may then be reacted with an aryl- or heteroarylbromide, such as 2-bromothiophene-5carboxaldehyde, in the presence of a palladium(0) catalyst, such as tetrakis(triphenylphosphine)palladium(0), or a palladium(II) catalyst, such as bis(triphenylphosphine)palladium(II) dichloride, in an aprotic solvent, such as dioxane, at temperatures ranging from 80 to $140^{\circ} \mathrm{C}$, preferably from 90 to $110^{\circ} \mathrm{C}$, to afford the corresponding 4 (aryl)phenyl or 4-(heteroaryl)phenyl substituted compound.

The compounds of formula $I$ in which $R^{1}$ represents a 4bromophenyl group may be converted into other compounds of formula $I$ in which $R^{1}$ represents a 4 -substituted alkyl- or
cycloalkylphenyl group, such as 4-cyclopentylphenyl by treatment of the corresponding bromide with an appropriate alkyl- or cycloalkyl Grignard reagent, such as cyclopentylmagnesium bromide, in the presence of a palladium(II) catalyst, such as [1,1'-bis(diphenylphosphino)ferrocene]dichloropalladium(II)( $\left.\mathrm{PdCl}_{2}(d \mathrm{ppf})\right)$, in an aprotic solvent, such as diethyl ether at temperatures ranging from $-78^{\circ} \mathrm{C}$ to $25^{\circ} \mathrm{C}$.

The compounds of formula $I$ in which $R^{1}$ represents a 4bromophenyl group may be converted into a 4-substituted carboxyaldehydephenyl(formylphenyl) group by reaction of the corresponding bromide with the carbon monoxide gas which is bubbled into the reaction under atmospheric pressure in the presence of a palladium(II) catalyst, such as bis(triphenylphosphine)palladium(II) dichloride and sodium formate in an aprotic solvent, such as dimethylformamide at temperatures ranging from 70 to $110^{\circ} \mathrm{C}$, preferably at $90^{\circ} \mathrm{C}$.

The compounds of formula $I$ in which $R^{1}$ represents a 4hydroxyphenyl group may be converted into other compounds of formula $I$ in which $R^{1}$ represents an alkoxy group by treatment of the corresponding hydroxyphenyl group with an appropriate alkylhalide such as benzylbromide in the presence of sodium hydride in an aprotic solvent such as dimethylformamide at temperatures ranging from 25 to $100^{\circ} \mathrm{C}$, preferably from 50 to $90^{\circ} \mathrm{C}$.

The compounds of formula II are known or may be prepared by conventional methods, for example by reducing a corresponding amide or nitrile using borane.

Some of the nitriles or amides used as starting materials may conveniently be prepared by treatment of an acetonitrile of formula $\mathrm{R}^{1} \mathrm{CH}_{2} \mathrm{CN}$, for example a substituted phenylacetonitrile such as 4-methoxyphenylacetonitrile or an acetate of formula $\mathrm{R}^{1} \mathrm{CH}_{2} \mathrm{COOR}$ (where R is, for example alkyl), for example a phenylacetate such as methyl 4-tertbutylphenylacetate, with a strong lithium amide base, such as sodium or lithium bis(trimethylsilyl) amide, and an alkylhalide, such as methyl iodide, in an aprotic solvent,
such as tetrahydrofuran, at a temperature ranging from -78 to $25^{\circ} \mathrm{C}$. The esters are converted to amides by hydrolysis (water, alcohol and sodium or potassium hydroxide) to the acid, conversion of the acid to the acid chloride (SOCl2 or (COCl) 2 plus DMF (1 drop)) then conversion to the amide with aqueous ammonia and a co-solvent such as tetrahydrofuran or dioxane.

Certain nitriles used to prepare compounds of formula II may also conveniently be prepared by reacting a corresponding ketone derivative, for example a compound of formula $\mathrm{R}^{1} \mathrm{COR}^{8}$, such as (2-acetyl-5-thien-3-yl)thiophene, with tosylmethylisocyanide and potassium t-butoxide in dimethyl ether.

The ability of compounds of formula I to potentiate glutamate receptor function may be demonstrated using the following test procedures.

96 well plates containing confluent monolayers of HEK cells stably expressing human GluR4B (obtained as described in European Patent Application Publication Number EP-A1583917) were prepared. The tissue culture medium in the wells was then discarded, and the wells were each washed once with $200 \mu \mathrm{l}$ of 5 NaCa buffer (glucose, 10 mM , sodium chloride, 138 mM , magnesium chloride, 1 mM , potassium chloride, 5 mM , calcium chloride, $5 \mathrm{mM}, \mathrm{N}-[2$-hydroxyethyl]-piperazine-N-[2-ethanesulfonic acid], 10 mM , to pH 7.1 to 7.3). The plates were then incubated for 60 minutes in the dark with $20 \mu \mathrm{M}$ Fluo3-AM dye (obtained from Molecular Probes Inc, Eugene, Oregon) in 5 NaCa buffer in each well. After the incubation, each well was washed once with $100 \mu \mathrm{~L}=5 \mathrm{NaCa}$ buffer, $200 \mu \mathrm{l}$ of 5 NaCa buffer was added and the plates were incubated for 30 minutes.

Solutions for use in the test were also prepared as follows. $30 \mu \mathrm{M}, 10 \mu \mathrm{M}, 3 \mu \mathrm{M}$ and $1 \mu \mathrm{M}$ dilutions of test compound were prepared using 5NaCa buffer from a 10 mM solution of test compound in DMSO. $100 \mu \mathrm{M}$ cyclothiazide solution was prepared by adding $3 \mu \mathrm{l}$ of 100 mM cyclothiazide
to 3 ml of 5 NaCa buffer. Control buffer solution was prepared by adding $1.5 \mu \mathrm{LI}$ DSO to $498.5 \mu \mathrm{l}$ of 5 NaCa buffer. Each test was then performed as follows. The $200 \mu \mathrm{l}$ of 5 NaCa buffer in each well was discarded, and replaced with $45 \mu \mathrm{l}$ of 5 NaCa buffer. A first reading was then taken using a FLUOROSKAN II fluorimeter (Obtained from Labsystems, Needham Heights, MA, USA, a Division of Life Sciences International Plc). The buffer was then discarded from the wells, $45 \mu \mathrm{l}$ of 5 NaCa buffer was added to the outer wells and $45 \mu \mathrm{l}$ of test compound solution was added to the inner wells. A second reading was then taken using the fluorimeter. The plate was then left in the fluorimeter for 5 minutes, and a third reading was taken. $15 \mu \mathrm{l}$ of $400 \mu \mathrm{M}$ glutamate solution was then added to each well (final glutamate concentration $100 \mu \mathrm{M}$ ), and a fourth reading was taken immediately. Approximately three minutes later, a fifth reading was taken.

The activities of test compounds, control and cyclothiazide solutions was determined by subtracting the third from the fourth reading (fluorescence due to glutamate). The activities of test compounds were expressed relative to that of $100 \mu \mathrm{M}$ cyclothiazide.

In another test, HEK293 cells stably expressing human GluR4 (obtained as described in European Patent Application Publication No. EP-A1-0583917) were used in the electrophysiological characterization of AMPA receptor potentiators. The extracellular recording solution contained (in mM): $140 \mathrm{NaCl}, 5 \mathrm{KCl}, 10 \mathrm{HEPES}, 1 \mathrm{MgCl} 2,2$ $\mathrm{CaCl}_{2}, 10$ glucose, $\mathrm{pH}=7.4$ with $\mathrm{NaOH}, 295 \mathrm{mOsm} \mathrm{kg}^{-1}$. The intracellular recording solution contained (in mM): 140 CsCl, $1 \mathrm{MgCl}_{2}, 10$ HEPES, ( N -[2-hydroxyethyl]piperazine- $\mathrm{N}^{1}$ -[2-ethanesulfonic acid]) 10 EGTA (ethylene-bis(oxyethylenenitrilo)tetraacetic acid), $\mathrm{pH}=7.2$ with CsOH, 295 mOsm $\mathrm{kg}^{-1}$. With these solutions, recording pipettes had a resistance of $2-3 \mathrm{M} \Omega$. Using the whole cell voltage clamp technique, cells were voltage-clamped at -60 mV and control responses to $100 \mu \mathrm{M}$ glutamate were evoked. Once stable
baseline responses to this agonist challenge were obtained, the potentiator was introduced in the extracellular solution bathing the cells at the lowest concentration, and the response to $100 \mu \mathrm{M}$ glutamate in the presence of this concentration of potentiator was determined.

The concentration of the potentiator, both in the bathing solution and co-applied with the agonist, was increased in half log units until the maximum potentiation was seen. Data collected in this manner was fit to the Hill equation, yielding an EC50 value, indicative of the potency of the potentiator. The potentiator was then washed out of both the control solution and the agonist-containing solution in order to investigate its reversal. Once the control responses to the agonist challenge were reestablished, the potentiation of these responses by $100 \mu \mathrm{M}$ cyclothiazide was determined by its inclusion in both the bathing solution and the agonist-containing solution. In this manner, the efficacy of the potentiator relative to that of cyclothiazide could be determined.

The compounds exemplified herein were found to give an EC50 in this test of at least $30 \mu \mathrm{M}$. For instance, the compound of Example 28 gave an EC50 of $230 \pm 59 \mathrm{nM}$.

According to another aspect, the present invention provides a pharmaceutical composition, which comprises a compound of formula $I$ a or a pharmaceutically acceptable salt thereof as defined hereinabove and a pharmaceutically acceptable diluent or carrier.

The pharmaceutical compositions are prepared by known procedures using well-known and readily available ingredients. In making the compositions of the present invention, the active ingredient will usually be mixed with a carrier, or diluted by a carrier, or enclosed within a carrier, and may be in the form of a capsule, sachet, paper, or other container. When the carrier serves as a diluent, it may be a solid, semi-solid, or liquid material which acts as a vehicle, excipient, or medium for the active ingredient. The compositions can be in the form of tablets,
pills, powders, lozenges, sachets, cachets, elixirs, suspensions, emulsions, solutions, syrups, aerosols, ointments containing, for example, up to $10 \%$ by weight of active compound, soft and hard gelatin capsules, suppositories, sterile injectable solutions, and sterile packaged powders.

Some examples of suitable carriers, excipients, and diluents include lactose, dextrose, sucrose, sorbitol, mannitol, starches, gum, acacia, calcium phosphate, alginates, tragcanth, gelatin, calcium silicate, microcrystalline cellulose, polyvinylpyrrolidone, cellulose, water syrup, methyl cellulose, methyl and propyl hydroxybenzoates, talc, magnesium stearate, and mineral oil. The formulations can additionally include lubricating agents, wetting agents, emulsifying and suspending agents, preserving agents, sweetening agents, or flavoring agents. Compositions of the invention may be formulated so as to provide quick, sustained, or delayed release of the active ingredient after administration to the patient by employing procedures well known in the art.

The compositions are preferably formulated in a unit dosage form, each dosage containing from about 1 mg to about 500 mg , more preferably about 5 mg to about 300 mg (for example 25 mg ) of the active ingredient. The term "unit dosage form" refers to a physically discrete unit suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of active material calculated to produce the desired therapeutic effect, in association with a suitable pharmaceutical carrier, diluent, or excipient. The following formulation examples are illustrative only and are not intended to limit the scope of the invention in any way.

## Formulation 1

Hard gelatin capsules are prepared using the following ingredients:

|  | Quantity <br> (mg/capsule) |
| :--- | :---: |
| Active Ingredient | 250 |
| Starch, dried |  |
| Magnesium stearate | 200 |
| Total | $\underline{10}$ |

The above ingredients are mixed and filled into hard gelatin capsules in 460 mg quantities.

Formulation 2
Tablets each containing 60 mg of active ingredient are made as follows:

| Active Ingredient | 60 mg |
| :--- | ---: |
| Starch | 45 mg |
| Microcrystalline cellulose | 35 mg |
| Polyvinylpyrrolidone | 4 mg |
| Sodium carboxymethyl starch | 4.5 mg |
| Magnesium stearate | 0.5 mg |
| Talc | 1 mg |
|  |  |
| Total | 150 mg |

The active ingredient, starch, and cellulose are passed through a No. 45 mesh U.S. sieve and mixed thoroughly. The solution of polyvinylpyrrolidone is mixed with the resultant powders which are then passed through a No. 14 mesh U.S. sieve. The granules so produced are dried at $50^{\circ} \mathrm{C}$ and passed through a No. 18 mesh U.S. sieve. The sodium carboxymethyl starch, magnesium stearate, and talc, previously passed through a No. 60 mesh U.S. sieve, are then
