WO 2011/159854 A1

CYCLOHEXYL-AZETIDINYL ANTAGONISTS OF CCR2

FIELD OF THE INVENTION

The invention is directed to substituted azetidine compounds, which are antagonists to the chemoattractant cytokine receptor 2 (CCR2), pharmaceutical compositions, and methods for use thereof. More particularly, the CCR2 antagonists are substituted cyclohexyl azetidiny compounds useful for preventing, treating or ameliorating a CCR2 mediated syndrome, disorder or disease.

BACKGROUND OF THE INVENTION

CCR2 is a member of the GPCR family of receptors, as are all known chemokine receptors, and are expressed by monocytes and memory T-lymphocytes. The CCR2 signaling cascade involves activation of phospholipases (PLC β 2), protein kinases (PKC), and lipid kinases (PI-3 kinase).

Chemoattractant cytokines (i.e., chemokines) are relatively small proteins (8-10 kD), which stimulate the migration of cells. The chemokine family is divided into four subfamilies based on the number of amino acid residues between the first and second highly conserved cysteines.

Monocyte chemoattractant protein-1 (MCP-1) is a member of the CC chemokine subfamily (wherein CC represents the subfamily having adjacent first and second cysteines) and binds to the cell-surface chemokine receptor 2 (CCR2). MCP-1 is a potent chemotactic factor, which, after binding to CCR2, mediates monocyte and lymphocyte migration (i.e., chemotaxis) toward a site of inflammation. MCP-1 is also expressed by cardiac muscle cells, blood vessel endothelial cells, fibroblasts, chondrocytes, smooth muscle cells, mesangial cells, alveolar cells, T-lymphocytes, macrophages, and the like.

After monocytes enter the inflammatory tissue and differentiate into macrophages, monocyte differentiation provides a secondary source of several proinflammatory modulators, including tumor necrosis factor- α (TNF- α), interleukin-1 (IL-1), IL-8 (a member of the CXC chemokine subfamily, wherein CXC represents one amino acid residue between the first and

second cysteines), IL-12, arachidonic acid metabolites (e.g., PGE₂ and LTB₄), oxygen-derived free radicals, matrix metalloproteinases, and complement components.

Animal model studies of chronic inflammatory diseases have demonstrated that inhibition of binding between MCP-1 and CCR2 by an antagonist suppresses the inflammatory response. The interaction between MCP-1 and CCR2 has been implicated (see Rollins B J, Monocyte chemoattractant protein 1: a potential regulator of monocyte recruitment in inflammatory disease, *Mol. Med. Today*, 1996, 2:198; and Dawson J, et al., Targeting monocyte chemoattractant protein-1 signaling in disease, *Expert Opin. Ther. Targets*, 2003 Feb. 7 (1):35-48) in inflammatory disease pathologies such as psoriasis, uveitis, atherosclerosis, rheumatoid arthritis (RA), multiple sclerosis, Crohn's Disease, nephritis, organ allograft rejection, fibroid lung, renal insufficiency, type II diabetes and diabetic complications, diabetic nephropathy, diabetic retinopathy, diabetic retinitis, diabetic microangiopathy, tuberculosis, sarcoidosis, invasive *staphylococci*, inflammation after cataract surgery, allergic rhinitis, allergic conjunctivitis, chronic urticaria, Chronic Obstructive Pulmonary Disease (COPD), allergic asthma, periodontal diseases, periodontitis, gingivitis, gum disease, diastolic cardiomyopathies, cardiac infarction, myocarditis, chronic heart failure, angiostenosis, restenosis, reperfusion disorders, glomerulonephritis, solid tumors and cancers, chronic lymphocytic leukemia, chronic myelocytic leukemia, multiple myeloma, malignant myeloma, Hodgkin's disease, and carcinomas of the bladder, breast, cervix, colon, lung, prostate, and stomach.

Monocyte migration is inhibited by MCP-1 antagonists (either antibodies or soluble, inactive fragments of MCP-1), which have been shown to inhibit the development of arthritis, asthma, and uveitis. Both MCP-1 and CCR2 knockout (KO) mice have demonstrated that monocyte infiltration into inflammatory lesions is significantly decreased. In addition, such KO mice are resistant to the development of experimental allergic encephalomyelitis (EAE, a model of human MS), cockroach allergen-induced asthma, atherosclerosis, and uveitis. Rheumatoid arthritis and Crohn's Disease patients have improved during treatment with TNF- α antagonists (e.g., monoclonal antibodies and soluble receptors) at dose levels correlated with decreases in MCP-1 expression and the number of infiltrating macrophages.

MCP-1 has been implicated in the pathogenesis of seasonal and chronic allergic rhinitis, having been found in the nasal mucosa of most patients with dust mite allergies. MCP-1 has also been found to induce histamine release from basophils in vitro. During allergic conditions, both

allergens and histamines have been shown to trigger (i.e. to up-regulate) the expression of MCP-1 and other chemokines in the nasal mucosa of people with allergic rhinitis, suggesting the presence of a positive feedback loop in such patients.

There remains a need for small molecule CCR2 antagonists for preventing, treating or ameliorating a CCR2 mediated inflammatory syndrome, disorder or disease resulting from MCP-1 induced monocyte and lymphocyte migration to a site of inflammation.

The term “C_(a-b)” (where *a* and *b* are integers referring to a designated number of carbon atoms) refers to an alkyl, alkenyl, alkynyl, alkoxy or cycloalkyl radical or to the alkyl portion of a radical in which alkyl appears as the prefix root containing from *a* to *b* carbon atoms inclusive. For example, C₍₁₋₄₎ denotes a radical containing 1, 2, 3 or 4 carbon atoms.

The term “cycloalkyl” refers to a saturated or partially unsaturated monocyclic or bicyclic hydrocarbon ring radical derived by the removal of one hydrogen atom from a single ring carbon atom. Typical cycloalkyl radicals include cyclopropyl, cyclobutyl, cyclopentyl, cyclopentenyl, cyclohexyl, cyclohexenyl, cycloheptyl and cyclooctyl. Additional examples include C₍₃₋₈₎cycloalkyl, C₍₅₋₈₎cycloalkyl, C₍₃₋₁₂₎cycloalkyl, C₍₃₋₂₀₎cycloalkyl, decahydronaphthalenyl, and 2,3,4,5,6,7-hexahydro-1H-indenyl.

The term “heteroaromatic” or “heteroaryl” refers to 5- to 7-membered mono- or 8- to 10-membered bicyclic aromatic ring systems, containing from one to four heteroatoms selected from N, O, or S where the nitrogen and sulfur atoms can exist in any allowed oxidation state. Examples include, but are not limited to, benzimidazolyl, benzothiazolyl, benzothienyl,

benzoxazolyl, furyl, imidazolyl, isothiazolyl, isoxazolyl, oxazolyl, pyrazinyl, pyrazolyl, pyridyl, pyrimidinyl, pyrrolyl, quinolinyl, thiazolyl and thienyl.

The term “heteroatom” refers to a nitrogen atom, an oxygen atom or a sulfur atom wherein the nitrogen and sulfur atoms can exist in any allowed oxidation states.

For use in medicines, the salts of the compounds of this invention refer to non-toxic “pharmaceutically acceptable salts.” FDA approved pharmaceutically acceptable salt forms (*Ref. International J. Pharm.* 1986, 33, 201-217; *J. Pharm. Sci.*, **1977**, Jan, 66(1), p1) include pharmaceutically acceptable acidic/anionic or basic/cationic salts.

Throughout this specification, compounds are described as being separated, usually by silica gel column, although preparatory thin layer chromatography, or high or low pressure liquid chromatography may also be used. It is generally accepted that when eluting compounds through a silica gel-type separation medium, that the least polar compounds elute before the more polar compounds. Therefore, the term “less polar isomer”, refers to the isomer that will elute first from a silica gel type separation medium.

Examples of a CCR2 mediated syndrome, disorder or disease for which the compounds of Formula I are useful include chronic obstructive pulmonary disorder (COPD), ophthalmic disorders, uveitis, atherosclerosis, rheumatoid arthritis, psoriasis, psoriatic arthritis, atopic dermatitis, multiple sclerosis, Crohn's Disease, ulcerative colitis, nephritis, organ allograft rejection, fibroid lung, renal insufficiency, type-I diabetes, type II diabetes, diabetic complications, diabetic nephropathy, diabetic retinopathy, diabetic retinitis, diabetic microangiopathy, overweight, obesity, obesity-associated insulin resistance, metabolic syndrome, tuberculosis, chronic obstructive pulmonary disease, sarcoidosis, invasive *staphylococci*, inflammation after cataract surgery, allergic rhinitis, allergic conjunctivitis, chronic urticaria, asthma, allergic asthma, periodontal diseases, periodontitis, gingivitis, gum disease, diastolic cardiomyopathies, cardiac infarction, myocarditis, chronic heart failure, angiostenosis, restenosis, reperfusion disorders, aortic abdominal aneurism, multiple sclerosis, glomerulonephritis, solid tumors and cancers, chronic lymphocytic leukemia, chronic myelocytic leukemia, multiple myeloma, malignant myeloma, Hodgkin's disease, carcinomas of the bladder, breast, cervix, colon, lung, prostate, or stomach, and chronic neuroinflammatory disorders including, but not limited to, Alzheimer's disease, ischemic stroke, spinal cord injury, nerve crush injury and traumatic brain injury.

The term "administering" with respect to the methods of the invention, means a method for therapeutically or prophylactically preventing, treating or ameliorating a syndrome, disorder or disease as described herein by using a compound of Formula I or a form, composition or medicament thereof. Such methods include administering an effective amount of said compound, compound form, composition or medicament at different times during the course of a therapy or concurrently in a combination form. The methods of the invention are to be understood as embracing all known therapeutic treatment regimens.

The term "subject" refers to a patient, which may be animal, typically a mammal, typically a human, which has been the object of treatment, observation or experiment. In one aspect of the invention, the subject is at risk of (or susceptible to) developing a syndrome, disorder or disease that is associated with elevated MCP-1 expression or MCP-1 overexpression, or a patient with an inflammatory condition that accompanies syndromes, disorders or diseases associated with elevated MCP-1 expression or MCP-1 overexpression.

The term "therapeutically effective amount" means that amount of active compound or pharmaceutical agent that elicits the biological or medicinal response in a tissue system, animal or human, that is being sought by a researcher, veterinarian, medical doctor, or other clinician, which includes preventing, treating or ameliorating the symptoms of a syndrome, disorder or disease being treated.

The term "uveitis" generically refers to any inflammatory disease involving the eye. Uveitis can be divided into clinically distinct subtypes based on the part of the eye in which the inflammation is present (percentages correspond to patients known to fit these categories): anterior (51%), intermediate (13%), posterior (20%), or panuveitis (16%) and, according to the course of the disease, as either acute (16%), recurring (26%), or chronic (58%). Those with anterior uveitis (19%) eventually develop irreparable vision damage despite aggressive treatment such as unilateral blindness (9%), bilateral blindness (2%), or unilateral or bilateral vision impairment (8%). Most cases of uveitis are idiopathic, but known causes include infection (e.g., toxoplasmosis, cytomegalovirus, and the like) or development as a component of a systemic inflammatory and/or autoimmune disorder (e.g., juvenile RA, HLA-B27 associated spondyloarthropathies, sarcoidosis, and the like). (HLA-B27: Human Leukocyte Antigen B*27- is a class I surface antigen encoded by the B locus in the major histocompatibility complex (MHC) on chromosome 6 and presents microbial antigens to T cells. HLA-B27 is strongly associated with a certain set of autoimmune diseases referred to as the seronegative spondyloarthropathies.)

When employed as CCR2 inhibitors, the compounds of the invention may be administered in an effective amount within the dosage range of about 0.5 mg to about 10 g, preferably between about 0.5 mg to about 5 g, in single or divided daily doses. The dosage administered will be affected by factors such as the route of administration, the health, weight and age of the recipient, the frequency of the treatment and the presence of concurrent and unrelated treatments.

It is also apparent to one skilled in the art that the therapeutically effective dose for compounds of the present invention or a pharmaceutical composition thereof will vary according to the desired effect. Therefore, optimal dosages to be administered may be readily determined by one skilled in the art and will vary with the particular compound used, the mode of administration, the strength of the preparation, and the advancement of the disease condition. In

addition, factors associated with the particular subject being treated, including subject age, weight, diet and time of administration, will result in the need to adjust the dose to an appropriate therapeutic level. The above dosages are thus exemplary of the average case. There can, of course, be individual instances where higher or lower dosage ranges are merited, and such are within the scope of this invention.

The compounds of Formula I may be formulated into pharmaceutical compositions comprising any known pharmaceutically acceptable carriers. Exemplary carriers include, but are not limited to, any suitable solvents, dispersion media, coatings, antibacterial and antifungal agents and isotonic agents. Exemplary excipients that may also be components of the formulation include fillers, binders, disintegrating agents and lubricants.

The pharmaceutically-acceptable salts of the compounds of Formula I include the conventional non-toxic salts or the quaternary ammonium salts which are formed from inorganic or organic acids or bases. Examples of such acid addition salts include acetate, adipate, benzoate, benzenesulfonate, citrate, camphorate, dodecylsulfate, hydrochloride, hydrobromide, lactate, maleate, methanesulfonate, nitrate, oxalate, pivalate, propionate, succinate, sulfate and tartrate. Base salts include ammonium salts, alkali metal salts such as sodium and potassium salts, alkaline earth metal salts such as calcium and magnesium salts, salts with organic bases such as dicyclohexylamino salts and salts with amino acids such as arginine. Also, the basic nitrogen-containing groups may be quaternized with, for example, alkyl halides.

The pharmaceutical compositions of the invention may be administered by any means that accomplish their intended purpose. Examples include administration by parenteral, subcutaneous, intravenous, intramuscular, intraperitoneal, transdermal, buccal or ocular routes. Alternatively or concurrently, administration may be by the oral route. Suitable formulations for parenteral administration include aqueous solutions of the active compounds in water-soluble form, for example, water-soluble salts, acidic solutions, alkaline solutions, dextrose-water solutions, isotonic carbohydrate solutions and cyclodextrin inclusion complexes.

The present invention also encompasses a method of making a pharmaceutical composition comprising mixing a pharmaceutically acceptable carrier with any of the compounds of the present invention. Additionally, the present invention includes pharmaceutical compositions made by mixing a pharmaceutically acceptable carrier with any of the compounds of the present invention. As used herein, the term "composition" is intended to encompass a

product comprising the specified ingredients in the specified amounts, as well as any product which results, directly or indirectly, from combinations of the specified ingredients in the specified amounts.

POLYMORPHS AND SOLVATES

Furthermore, the compounds of the present invention may have one or more polymorph or amorphous crystalline forms and as such are intended to be included in the scope of the invention. In addition, the compounds may form solvates, for example with water (i.e., hydrates) or common organic solvents. As used herein, the term "solvate" means a physical association of the compounds of the present invention with one or more solvent molecules. This physical association involves varying degrees of ionic and covalent bonding, including hydrogen bonding. In certain instances the solvate will be capable of isolation, for example when one or more solvent molecules are incorporated in the crystal lattice of the crystalline solid. The term "solvate" is intended to encompass both solution-phase and isolatable solvates. Non-limiting examples of suitable solvates include ethanولات, methanولات, and the like.

It is intended that the present invention include within its scope polymorphs and solvates of the compounds of the present invention. Thus, in the methods of treatment of the present invention, the term "administering" shall encompass the means for treating, ameliorating or preventing a syndrome, disorder or disease described herein with the compounds of the present invention or a polymorph or solvate thereof, which would obviously be included within the scope of the invention albeit not specifically disclosed.

In another embodiment, the invention relates to a compound as described in the Examples or Formula I for use as a medicament.

In another embodiment, the invention relates to the use of a compound as described in the Examples of Formula I for the preparation of a medicament for the treatment of a disease associated with an elevated or inappropriate CCR2 activity.

The present invention includes within its scope prodrugs of the compounds of this invention. In general, such prodrugs will be functional derivatives of the compounds which are readily convertible *in vivo* into the required compound. Thus, in the methods of treatment of the present invention, the term "administering" shall encompass the treatment of the various disorders described with the compound specifically disclosed or with a compound which may not be specifically disclosed, but which converts to the specified compound *in vivo* after

administration to the patient. Conventional procedures for the selection and preparation of suitable prodrug derivatives are described, for example, in "Design of Prodrugs", Ed. H. Bundgaard, Elsevier, 1985.

Where the compounds according to this invention have at least one chiral center, they may accordingly exist as enantiomers. Where the compounds possess two or more chiral centers, they may additionally exist as diastereomers. It is to be understood that all such isomers and mixtures thereof are encompassed within the scope of the present invention.

Where the processes for the preparation of the compounds according to the invention give rise to mixture of stereoisomers, these isomers may be separated by conventional techniques such as preparative chromatography. The compounds may be prepared in racemic form, or individual enantiomers may be prepared either by enantiospecific synthesis or by resolution. The compounds may, for example, be resolved into their component enantiomers by standard techniques, such as the formation of diastereomeric pairs by salt formation with an optically active acid, such as (-)-di-p-toluoyl-D-tartaric acid and/or (+)-di-p-toluoyl-L-tartaric acid followed by fractional crystallization and regeneration of the free base. The compounds may also be resolved by formation of diastereomeric esters or amides, followed by chromatographic separation and removal of the chiral auxiliary. Alternatively, the compounds may be resolved using a chiral HPLC column.

During any of the processes for preparation of the compounds of the present invention, it may be necessary and/or desirable to protect sensitive or reactive groups on any of the molecules concerned. This may be achieved by means of conventional protecting groups, such as those described in Protective Groups in Organic Chemistry, ed. J.F.W. McOmie, Plenum Press, 1973; and T.W. Greene & P.G.M. Wuts, Protective Groups in Organic Synthesis, John Wiley & Sons, 1991. The protecting groups may be removed at a convenient subsequent stage using methods known from the art.

Example 64: N-(1-((1*r*,4*r*)-4-hydroxy-4-(thiazol-2-yl)cyclohexyl)azetidin-3-yl)-2-(methyl(6-(trifluoromethyl)quinazolin-4-yl)amino)acetamide

Step A: ethyl 2-(((benzyloxy)carbonyl)(methyl)amino)acetate

A rapidly stirred mixture of ethyl acetate and saturated aqueous sodium bicarbonate containing commercially available 2 ethyl 2-(methylamino)acetate (1.91 g, 12.4 mmol, HCl salt) was cooled to 0 °C and treated dropwise with benzyl chloroformate (4.10 mL, 12.3 mmol). After stirring overnight warming to room temperature, the aqueous layer was removed and the organic layer concentrated in vacuo. Purification of the residue by flash chromatography (silica gel, DCM) yielded the product.

Step B: 2-(((benzyloxy)carbonyl)(methyl)amino)acetic acid

After stirring at room temperature for 3 hours, the pH was adjusted to ~5 by the addition of aqueous HCl. After extraction with ethyl acetate, the organic layer was dried over Na₂SO₄ and concentrated in vacuo to yield the product.

Step C: tert-butyl 3-(2-(((benzyloxy)carbonyl)(methyl)amino)acetamido)azetidine-1-carboxylate

The reaction mixture was stirred at room temperature overnight and then concentrated in vacuo. The residue was dissolved in ethyl acetate, washed with saturated ammonium chloride solution, 1 N NaOH solution, brine and the organic layer dried over Na₂SO₄. After concentration in vacuo, the residue was purified by flash chromatography (silica gel, 0%-5% MeOH/EtOAc) to give a white solid after drying under high vacuum.

The flask was evacuated and back filled with argon. Methanol (100 mL) was carefully added via syringe and the flask was evacuated with stirring. It was then back filled with hydrogen and stirred 2 days under a hydrogen balloon. After evacuation with stirring and back filling with argon, the catalyst was removed by filtration over Celite 521 and concentrated in vacuo to afford the product.

Step E: tert-butyl 3-(2-(methyl(6-(trifluoromethyl)quinazolin-4-yl)amino)acetamido)azetidine-1-carboxylate

The reaction was stirred overnight at room temperature. The solvent was removed in vacuo and the residue first triturated with ether, decanting the supernatant, and dried on the high vacuum to give the title compound as a TFA salt containing extra TFA (colorless foam). The amount of TFA varied from run to run and was determined by integration of the ^{19}F NMR signals of the aryl CF_3 and the CF_3 from TFA.

Step A: 2,6-bis(trifluoromethyl)quinazolin-4-ol

A mixture of Trifluoroacetic anhydride (0.882 mL, 6.35 mmol) and 2-amino-5-(trifluoromethyl)benzoic acid (425 mg, 2.01 mmol) were suspended in heptane (40 mL) and heated under Dean-Stark conditions at 110 °C for 18 hours. After cooling to room temperature, reaction mixture was concentrated in vacuo to 15 mL volume, treated acetic acid, concentrated again to 30 mL total volume, ammonium acetate (1 g, 13 mmol) was added and the mixture was heated to for 4 days. After cooling to room temperature, the reaction was concentrated to dryness in vacuo, and the residue slowly quenched with saturated aqueous NaHCO₃. The resulting precipitate was collected by filtration, washed with water and heptanes and dried in vacuo to afford the product as a gold solid.

Step A: N-(1-{1,4-dioxaspiro[4.5]decan-8-yl}propyl)-2,2,2-trifluoroacetamide

Into a 50 mL round-bottom flask was placed a solution of 1-1,4-dioxaspiro[4.5]decan-8-ylpropan-1-amine hydrochloride (as prepared in Example 104, Step B) (100 mg, 0.42 mmol, 1.00 equiv) in dichloromethane (10 mL) and TEA (85.6 mg, 0.85 mmol, 2.00 equiv). This was followed by the addition of 2,2,2-trifluoroacetyl 2,2,2-trifluoroacetate (107 mg, 0.51 mmol, 1.20 equiv) dropwise with stirring at 0 °C. The resulting solution was stirred overnight at room temperature, then quenched by the addition of 20 mL of water. The resulting solution was

extracted with 2x20 mL of dichloromethane. The organic layers were combined, dried over anhydrous sodium sulfate and concentrated under vacuum. This resulted in 89 mg (crude) of N-(1-{1,4-dioxaspiro[4.5]decan-8-yl}propyl)-2,2,2-trifluoroacetamide as a yellow solid.

Step B: 2,2,2-trifluoro-N-(1-(4-oxocyclohexyl)propyl)acetamide

The resulting mixture was concentrated under vacuum. The residue was diluted with 10 mL of aq. sodium bicarbonate (1M). The resulting solution was extracted with 2x20 mL of dichloromethane. The organic layers were combined, dried over anhydrous sodium sulfate and concentrated under vacuum to give the title compound as a yellow oil.

Step C: 2,2,2-trifluoro-N-((S)-1-((1S,4R)-4-(3-(2-((6-(trifluoromethyl)quinazolin-4-yl)amino)acetamido)azetidin-1-yl)cyclohexyl)propyl)acetamide

Into a 50 mL round-bottom flask were placed a solution of 2,2,2-trifluoro-N-(1-(4-oxocyclohexyl)propyl)acetamide (66 mg, 0.26 mmol, 1.00 equiv) in dichloromethane (10 mL), N-(azetidin-3-yl)-2-(6-(trifluoromethyl)quinazolin-4-ylamino)acetamide 2,2,2-trifluoroacetic acid (as prepared in Example 1, Step G) (126 mg, 0.29 mmol, 1.10 equiv) and TEA (27 mg, 0.27 mmol, 1.00 equiv). The resulting solution was stirred for 30 min at room temperature, then added NaBH(OAc)₃ (201 mg, 0.95 mmol, 3.60 equiv). The resulting solution was stirred for an additional 2 h at room temperature, then it was concentrated under vacuum. The crude product was purified by Prep-HPLC with the following conditions: Column, Xbridge phenyl, 5 μm,

19x150mm; mobile phase, water (0.03% NH₃H₂O) and CH₃CN; Detector, UV 254nm. The title compound was obtained as a white solid.

The resulting solution was stirred overnight at room temperature. This was followed by the addition of a solution of NaN₃ (4.6 g, 70.77 mmol, 1.98 equiv) in water (40 mL) dropwise with stirring at

0 °C in 1 min. The reaction mixture was stirred for 3 hours at 70 °C. The resulting solution was diluted with 100 mL of DCM, was washed with 3x50 mL of sodium bicarbonate/H₂O, and was concentrated under vacuum. This resulted in 800 mg (25%) of 3-aminocyclobutanone as yellow oil.

Step B: tert-butyl 3-oxocyclobutylcarbamate

Into a 50 mL round-bottom flask, was placed a solution of 3-aminocyclobutanone (as prepared in the previous step) (250 mg, 2.94 mmol, 1.00 equiv) in N, N-dimethylformamide (15 mL), triethylamine (351 mg, 3.48 mmol) and (Boc)₂O (697 mg, 3.20 mmol, 1.09 equiv). The reaction mixture was stirred for 5 h at room temperature. The reaction was then quenched by the addition of 10 mL of H₂O. The resulting solution was extracted with 3x20 mL of ethyl acetate. The combined organic layers was washed with 3x10 mL brine, dried over sodium sulfate, and concentrated under vacuum. The title compound was obtained as a yellow solid.

This was followed by the addition of n-BuLi (3.7 mL, 1.20 equiv) dropwise with stirring at -78 °C in 1 hr. After half-hour, the benzyl 4-oxopiperidine-1-carboxylate (1.85 g, 7.94 mmol, 1.00 equiv) was added dropwise with stirring at -78 °C in 0.5 hr. The resulting solution was extracted with 3x100 mL of ethyl acetate, and the combined organic layers washed with 2x100 mL of brine, dried (Na₂SO₄), and concentrated under vacuum. The residue was purified by chromatography over a silica gel column with ethyl acetate/petroleum ether (1:20-1:1). Compounds of the invention were subjected to various representative biological tests. The results of these tests are intended to illustrate the invention in a non-limiting fashion.

MCP-1 Receptor Binding Assay in THP-1 Cells

Human monocytic cell line THP-1 cells were obtained from American Type Culture Collection (Manassas, Va., USA). The THP-1 cells were grown in RPMI-1640 (RPMI: Roswell Park Memorial Institute Medium-cell culture growth media) supplemented with 10% fetal bovine serum in a humidified 5% CO₂ atmosphere at 37 °C. The cell density was maintained between 0.5×10⁶ cells/mL.

THP-1 (cells were incubated with 0.5 nM ¹²⁵I labeled MCP-1 (Perkin-Elmer Life Sciences, Inc. Boston, Mass.) in the presence of varying concentrations of either unlabeled MCP-1 (R & D Systems, Minneapolis, Minn.) or test compound for 2 hours at 30 °C. in a 96 well plate. Cells were then harvested onto a filter plate, dried, and 20 μ L of Microscint 20 was added to each well. Plates were counted in a TopCount NXT, Microplate Scintillation & Luminescence Counter (Perkin-Elmer Life Sciences, Inc. Boston, Mass.). Blank values (buffer only) were subtracted from all values and drug treated values were compared to vehicle treated values. 1 μ M cold MCP-1 was used for nonspecific binding.

Table 1 lists IC₅₀ values for inhibition of MCP-1 binding to CCR2 obtained for test compounds of the invention. Where an IC₅₀ value was not obtained for a particular compound, the percent inhibition is provided at a test concentration of 25 μ M.

Example 172: Animals.

Mouse CCR2 knock-out / human CCR2 knock-in mice are generated using targeted 129Sv/Evbrd embryonic stem cell clones injected into C57BL/6 mice. Expression of the *hCCR2* transcript is confirmed by quantitative reverse transcription-polymerase chain reaction performed on spleen and blood total RNA from homozygous hCCR2 knock-in mice. Backcrossing into C57BL/6 genetic background continued to the eighth generation. Transgenic mice are housed in a specific-pathogen-free, temperature-controlled facility that maintained a 12-hour light/12-hour dark cycle. Mice have free access to water and food. Experimental procedures are carried out in accordance with institutional standards for animal care and are approved by the institute's animal care and use committee.

Example 173: Murine In vivo Cell Migration Assay.

Animals are orally dosed with vehicle or CCR2 antagonists at 3, 10 and 30 mg/kg bid. Animals undergo anesthesia and laparotomy. A distal loop of small bowel (5 cm in length) is gently everted onto moist sterile gauze. Synthetic human MCP-1 (1 mg/100 ml sterile PBS) or PBS alone is administered drop-wise onto the serosa of the everted loop. A suture knot is placed into the mesentery to mark the terminus of the treated area. Twenty-four hours later, the animal is sacrificed and the segment of bowel plus the adjacent region is removed. The tissue is opened along the mesenteric border, pinned flat and the mucosa removed. The remaining muscle layer is fixed briefly in 100% EtOH and then stained using Hanker-Yates reagent to detect myeloperoxidase-containing immune cells. At 10 mpk, P.O. bid, a compound is deemed efficacious if the inhibition of cell migration reaches 30% compared with vehicle-treated animals.

Example 174: Thiolycollate-Induced Peritonitis in Mice.

Animals are orally dosed with vehicle or CCR2 antagonists at 3, 10, 30 and 100 mg/kg bid). One hour later, the animals are intraperitoneally injected with sterile thioglycollate (25 mL/kg, ip, Sigma) for induction of peritonitis. Animals are orally treated twice daily with vehicle or CCR2 antagonists. At 72-hour time point, peritoneal cavities are lavaged with 10 mL of sterile saline. Total cell counts in the peritoneal lavage fluid are performed using a microscope and cell differentiation was performed using cytospin analysis after Giemsa staining (Hema Tek 2000). Percent inhibition of the thioglycollate-induced peritonitis is calculated by comparing the change in number of leukocytes of CCR2 antagonist treated mice to the vehicle-treated mice.

Example 175: MCP-1-Induced Monocyte Recruitment to Airway of Mice.

Animals are orally treated with vehicle or CCR2 antagonists at 3, 10, and 30 mg/kg po bid). One hour later, the animals are intranasally dosed with 4 µg of MCP-1 in sterile saline. The animals are orally treated twice daily with vehicle or CCR2 antagonists. After 48 h, mice are euthanized by intraperitoneal injection of anesthesia solution (Sleepaway-Sodium pentobarbital). Whole bronchoalveolar lavage (BAL) is performed using 1.4 mL of ice-cold PBS containing 3 mM EDTA. Total cell counts in the BAL lavage fluid are performed using a microscope and cell differentiation was performed using cytospin analysis after Giemsa staining (Hema Tek 2000). Percent inhibition is calculated by comparing the change in number of total leukocyte counts (including monocytes/macrophages and lymphocytes) of compound-treated mice to the vehicle-treated mice. Compounds are deemed efficacious if percent inhibition reaches 30%.

Example 176: High-fat Diet Induced Obesity and Insulin Resistance in Mice.

Obesity is induced by a high-fat diet that derived approximately 60% calories from lipids (D-12492; Research Diets Inc.) in animals for 10- 24 weeks at age of 7 weeks. Prior to age 7 weeks, animals are fed a standard pellet diet, in which 5% of calories are provided as fat. Obese animals are randomized by body weight and fat mass. The obese animals are orally treated with vehicle or CCR2 antagonists at 3, 10 and 30 mg/kg, po bid. Body weight and food intake and fasting blood glucose levels are monitored. Body mass is determined by a NMR analyzer (Burker MiniSpec). Insulin tolerance test is carried out in animals that fasted for 3 hours. After an intraperitoneal bolus injection of recombinant human insulin (1.5 U/kg), blood glucose

concentrations are measured using a Glucometer before and 15, 30, 45, 60, 90 and 120 minutes after injection. Glucose tolerance tests are performed after an overnight (17-hour) fast. Blood glucose concentrations are measured before and after 15, 30, 60, 90, 120 minutes after an oral dose of glucose dissolved in water (1g/kg). Energy expenditure analysis is monitored by a complete laboratory animal monitor system. After 40 days treatment with vehicle or CCR2 antagonists, the animals are sacrificed by CO₂ asphyxiation. Percent of weight loss is calculated by comparing the body weight changes of the compound-treated mice with the vehicle-treated mice.

Example 177: Mouse Model of Allergic Asthma.

Animals are sensitized by intraperitoneal injection of 10 µg chicken egg albumin (OVA) absorbed to 1 mg Imject[®] in 100 µL phosphate-buffered saline (PBS) on days 0 and 5. Control animals receive PBS ip. OVA-immunized animals are challenged by inhalation of 0.5% OVA aerosol for 10 minutes by an ultrasonic nebulizer on days 12, 16 and 20. Control animals are challenged with PBS in similar fashion. The OVA-sensitized animals receive vehicle (0.5% Methocel) or CCR2 antagonists orally at 3, 10, 30 mg/kg twice daily from days 9-20 and once daily on day 21, 2 hours before sacrifice. Dexamethason (5 mg/kg) and Montelukast (1 mg/kg) are given orally once a day. On day 21, 2 hours post the last dose of CCR2 compounds, bronchial reactivity to aerosolized methacholine is measured using a Buxco whole body plethysmograph. On day 21, the animals are sacrificed. Bronchoalveolar lavage fluid is collected (1 mL) and total cells counted. The numbers of eosinophils, lymphocytes, monocytes and neutrophils are determined using cytopsin analysis after Giemsa staining (Hema Tek 2000). Percent inhibition of total BAL leukocyte count (and eosinophil count) is calculated by comparing the compound-treated mice with vehicle-treated mice. Compounds are deemed efficacious if the inhibition reaches 30%.
